The date shows when this volume was taken.

HOME USE RULES.

Books not needed for instruction or research are returnable within 4 weeks.

Volumes of periodicals and of pamphlets are held in the library as much as possible. For special purposes they are given out for a limited time.

Borrowers should not use their library privileges for the benefit of other persons.

Books not needed during recess periods should be returned to the library, or arrangements made for their return during borrower's absence, if wanted.

Books needed by more than one person are held on the reserve list.

Books of special value and gift books, when the giver wishes it, are not allowed to circulate.

VOL. XXVIII. NEW YORK, JANUARY 4, 1905. NO. 1.

ELECTRICITY.

Published every Wednesday by the
ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.
Long Distance Telephone, 4021 Cortlandt

SUBSCRIPTION RATES:
United States, Canada and Mexico..$1.00
Foreign Countries...................... 3.00
Single Copies......................10 cents
Remit by Draft. Post Office Order, Registered Letter or in Stamps.

Owing to the expense involved in keeping back numbers, papers over two years old will be charged for at the rate of 25 cents apiece.

ADVERTISING RATES.

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than Saturday morning preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

EDITORIAL NOTES.

A Word About "Electricity."

As a general rule we do not consider it either seemly or becoming for a journal to "blow its own horn." This issue, however, being the first of the New Year, we deem it necessary to call our readers' attention to a few features of ELECTRICITY as they were last year and as we propose to make them during the next twelve months.

During 1904 there appeared in the columns of this journal, besides a large number of excellent short articles, several serials by authoritative writers. The subjects covered by the latter were electrical station practice, steam boiler pressures, Corliss engines and electric wiring.

At the present time a serial entitled "Electricity Leaflets" is running, which should prove of great value to the practical man who wishes to more thoroughly familiarize himself with the subject of electrical engineering. During 1905 our intention is to present to our subscribers articles of merit by well-known writers, both in this country and abroad. These articles will be up-to-date and will be devoid of hieroglyphics and intricate mathematics, but will nevertheless be technically correct.

The General News Department will be carefully looked after and every effort made to publish as early as possible information as to where bids are wanted.

That our efforts during 1904 have been appreciated may be inferred from the large number of new subscribers that have been added to our list. More will be added this year and it is our intention and determination to give to the public for $1 a year so large and choice an amount of reading matter that they will feel compelled to subscribe.

Oil as a Power Producer.

Illimitable coal fields do not compensate for the costliness of steam power producers. The inherent defect remains as ineradicable to-day as in the past. The unfortunate items of radiation and condensation, of heat escaping up the chimney and combustive processes which represent heavy losses—all of these, summed up, are the total which detracts from the whole, which levels beautiful theories to the ground and makes all improvements merely fancy frills to a finished and unchangeable fabric. The defects referred to as ineradicable are the natural defects of reciprocating steam engines. But this does not mean that such gloomy conclusions must be drawn with respect to other reciprocating forms of power producers. This is not the case, for instance, with the gas or oil engine, and particularly not the case with regard to those engines which utilize crude oil.

Nature has stored away deep down in the bowels of the earth vast reservoirs of oil. Here, as one of the last feats performed by this economical and perpetually busy housewife, she has gathered up from the gigantic pits which served as graves for her prehistoric forests, in vast subterranean pools, the exudations of these slowly carbonizing masses—known to-day by the descriptive and explicit title of "natural oil."

This, perhaps is the savior of mankind in the field of cheap electric power production, and in this respect it must be stated that oil engines carry within themselves hosts of possibilities of the utmost importance to theoreticians, engineers and financiers.

And why is this so? may be very properly asked by those whose curiosity cannot find an adequate response without help from technical statistics. The reasons briefly stated are these: Engines which consume crude oil successfully are far ahead in cheapness of operation of those depending upon other forms of combustible fluids. Both efficiency and cheapness can claim prominence in this category of advantages. Then comes the important feature of a concentrated form of fuel. Liquid fuel is certainly the advance agent of progress. Take the Diesel engine in which ignition of the oil in a highly desiccated form takes place through it coming in contact with a portion of air so highly compressed that its temperature rises to a point which excites combustion. Here, then, is an engine which represents certain theoretical ideals which have been largely crystallized in its construction. It consumes a crude form of oil; its cheapness of operation gives it prominence without further comment. It is a type of the oil consuming engine which threatens to predominate in the near future. It is not mentioned here except as a unique type which offers a solution of that all-important problem, "cheap electricity." Coal has had its day, not because it is not a cheap and satisfactory fuel, but because the steam engine is about to undergo a great revolution in construction. And this revolution is but the beginning of a series of vast changes in the economy of electric power houses, which must lead to the production of electricity for the public at prices the humblest of homes can pay.

* * *

Refuse Burning and Electricity Generation.

The most exhaustive independent examination that has yet been made of the actual steam raising values obtained in the working of combined dust destructors and electricity works is that recently issued by an English consulting electrical engineer, Mr. W. P. Adams. In the course of detailed analyses of the results which have been recorded by the engineers of different types of plants in different parts of the United Kingdom, he has obtained figures which afford convincing evidence that great advances have been made in the problem of utilizing waste heat since the pioneering destructor installations were put down. The results still leave room for substantial improvement, however, by closer attention to the details of construction of furnaces and flues, and the general arrangement of the plant; also by improving the methods of handling and burning the refuse, by careful utilization of the steam generated, and by the adoption of an economical form of blast. Mr. Adams expresses the conviction that, given suitable conditions, there is undoubtedly a substantial gain to be affected by the combination of electricity and destructor works; but owing to the variation in the calorific value of refuse in different localities, and to other special local considerations, every proposed case of combination needs to be considered on its merits by persons qualified to make an independent and intelligent inquiry. Wherever such combined undertakings exist it is most desirable that the accounts of each department be separately kept so that it may be possible to have a true record of the real extent of the value of combination.

To English electrical engineers especially, Mr. Adams' collection of data is of great value because of the many plants that have lately been erected and because of the increasing popularity of combined systems with municipal authorities in England. The paper, which was read before the London Institution of Electrical Engineers on December 15, contains many statistical tables of interest.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

The Cleveland (O.) Electric Company will experiment in 3-cent fares for a distance of two miles from the center of the city.

At the recent meeting of the Benjamin Franklin fund managers in Boston a letter was read from President Henry S. Pritchett of the Massachusetts Institute of Technology containing a proposition from Andrew Carnegie to duplicate the amount of the fund, which has now reached $400,000, provided the total be devoted to the establishment of a school for the industrial training of men and women along the lines of the Mechanics and Tradesmen's School, of New York, and the Cooper Union, the city of Boston to furnish a site. The board voted to thank Mr. Carnegie for his offer and to give the matter early consideration.

Chief Engineer William Barclay Parsons has submitted to the New York Rapid Transit Commission plans for additional lines in Manhattan, the Bronx and Brooklyn, which, if carried out, are calculated to go far toward solving the rapid transit problem. The estimated cost of the proposed new lines in Manhattan is about $40,000,000 and the extension of the Subway system in the Bronx and Brooklyn will involve an outlay of $9,000,000. The Commission will hold a public hearing a week from next Thursday.

Rear Admiral Colby M. Chester, in charge of the United States Observatory at Washington, D. C., on Monday night received a cablegram from Sydney, Australia, indicating that the New Year's flash to that point on New Year's night, broke the record. The flash went from Washington to Sydney, 12,000 miles, over relays, in 2.96 seconds. "This," said Lenehan, operator at Sydney, "is a triumph for the electrical department of the American Observatory. Congratulations."

It is announced officially that the Merchant's Association of New York is preparing for submission to the Legislature an act to regulate the price of electric lighting in the same way as the price of gas is now regulated. The act will apply to private consumers as well as to the city, and there will be a unit of price—so much per kilowatt hour—with penalties for violations of the act.

Ningpo, China, is shortly to have an electric lighting plant which will supply 4,000 lights.

Consul Nason reports from Grenoble, France, that the utilization of the enormous power of the mountain streams and glaciers, called the "white coal," is year by year attaining larger proportions. The last achievement is the lighting of the entire city by electricity generated 27 miles away. Ornate standards, 30 feet high, with curving pendants terminating with powerful arc lights, have been erected in the streets, and the full illumination, after a period of testing, is soon to be made the object of a festival night.

A civil service examination will be held in Cleveland, O., January 18 for aids and laboratory apprentices, Department of Commerce and Labor. January 18-19 there will be examinations for inspectors of mechanical and electrical engineering in the office of the supervising architect and assistants to the chief inspector of the quartermaster's department at Philadelphia. The position of laboratory aids and apprentices will pay $480 a year, engineering inspectors $2,190 a year and assistant to the chief inspector $1,500 a year.

The submarine tunnel connecting Boston and East Boston was opened for public travel last Friday. About 40 trolley cars of special adaptability are in use.

TELEPHONE PROTECTIVE DEVICES.

BY RALPH SCOTT.

A telephone arrester or diverter is a device for protecting a telephone from injury by lightning or other static high potential discharges. These discharges are usually the result of the tendency of the atmospheric electricity to pass to ground. When lightning strikes a telephone line wire, it passes along this line to the nearest instrument or set of instruments and thence to ground, depending upon the facilities which have been provided for its escape. An unprotected instrument is at best a hazardous unit during a lightning storm, either to itself or to the adjacent person or buildings.

The protection of telephone circuits has become lately a very important matter, both to the subscriber and also to the company. The subscriber looks at the question of lightning protection from a view of security and safety, since there are numerous cases with which he is familiar, of poorly protected telephones being frequently the cause of dangerous fires or accidents.

The company, on the other hand, views complete protection from the standpoint of the saving of apparatus, since its experience has shown that a small outlay in protective devices is usually more than compensated by the minimizing of the loss of instruments due to the destructive discharge.

In designing an arrester which will be satisfactory, therefore, it is necessary to consider both the subscriber and the company, so that the protection afforded will be both a means of saving property or life, and also the means of saving the instrument to which the device is connected.

Much effort has been expended in devising and improving arresters for telephone protection. A discharge of lightning that would not affect a telegraph instrument or similar appliance would be absolutely fatal to a telephone. This is because of the fact that a telephone contains a number of flimsy and minute devices that require but little disturbance to be put out of order. Also it is not safe to allow an impeded lightning discharge to enter a house or other building without a safe means of escaping to the ground.

When telephony had not as yet become an established industry it was classed in construction work in the same light as the then well-established telegraphy. The line construction, together with the installation of the central offices, was placed in the hands of men experienced in the art of telegraphy. The result of the reversion was the pressing into service of construction and protection material which has become standard in telegraph work. As high tension circuits were not at that time as frequent as at the present, the only trouble which had to be guarded against was that caused by lightning. For the protection of the instruments and stations against lightning, telegraph lightning arresters were employed.

These arresters consisted of metal plates separated by an air-gap or by a piece of paraffined paper. This arrester proved fairly efficient for separate line work, but when cables were introduced its operation was entirely unsatisfactory. The result was the new designs of arresters were attempted, among the earliest of which was that formed by wrapping a few turns of wire around a grounded rod, this wire being insulated from the rod by means of paper. This device proved itself fairly effective, but the increased use of high tension currents and the extension of trolley system brought further trouble which could not be obviated by this device. This trouble, known as foreign currents, brought about the construction of an entirely different set of apparatus, which at the present time is in a remarkable state of perfection. The forerunner of these protectors was an electric magnet in series with which was a circuit opener operated by the magnet itself. When a current passed through the magnet which was stronger than the allowable amount, the circuit was opened by the magnet much in the manner of an overload circuit breaker.

A lightning or other static discharge consists of an enormous number of oscillatory surges. It has been estimated that a discharge of lightning consists in reality of about 100,000,000 surgings back and forth; although it is probable that the entire flash does not occupy more than one-millionth of a second. By reason of this frequency such a discharge will not pass through even a very slight impedance. On account of its enormously high potential, however, it will readily pass through a very high ohmic resistance, providing this resistance be in a perfectly straight line.

To show the effects of impedance, the loop shown in Fig. 1 should be considered. If a discharge of lightning passes initially from E to S, the loop L, and the curves 00 will offer such a great amount of impedance that the discharge will jump across the air-gap at A.

The formula for impedance in ohms is:

$$\sqrt{R^2 + (2 \times 3.1416\ n\,L)^2}$$

In which n is the frequency, R the resistance and L the inductance. On account of the great value which n has when dealing with lightning it is seen that the impedance becomes great even though L is small.

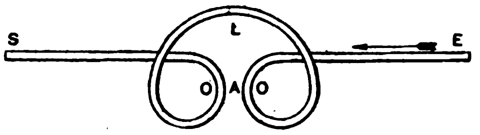

Fig. 1.

The surges which occur during the lightning discharge are shown diagrammatically in Fig. 2, being alternately positive and negative in direction, and gradually decreasing in intensity, as shown by the position of the ordinates with respect to the line AB.

The effect of inductance may be given the following mechanical analogy: Suppose that a wheel provided with spokes be set in motion by a crank which is so solidly constructed as to be unbreakable. If now the wheel be set in back and forth motion by this crank slowly, the strain imposed upon the spokes by reason of the inertia of the rim will be very small. If, however, the wheel be quickly started, in first one direction and then another, the strain upon the spokes will be increased. If such motion be set up very rapidly the spokes will be broken.

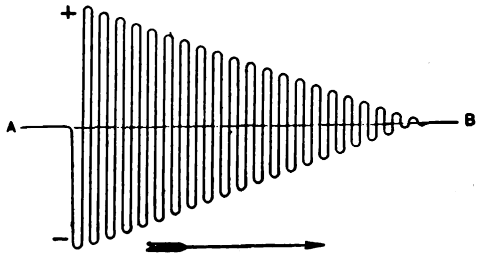

Fig. 2.

The exact nature of the lightning discharge is not understood, although recently considerable discussion and research has been carried out for the purpose of increasing this knowledge. In view of this research a summarization shows that the uncertainty of the action of lightning is known to a far greater degree than formerly. The result is that definite laws which might be laid down as covering the theory of lightning seem farther off at the present time than ever before.

The best answer that can be given to the question, "How may apparatus be best protected?" is: by providing as many paths as possible for the lightning to escape to the earth.

It is well known that such a discharge has certain selective tendencies, which are not greatly overcome by ohmic resistance, but are much so by the slightest impedance. The paths to the ground should be provided at such points as it is known that the lightning is most likely to pass.

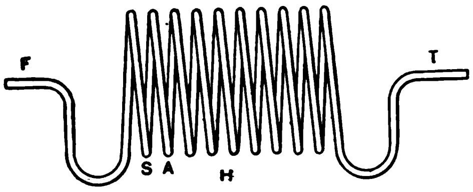

FIG. 3.

If we consider the solenoid H, shown in Fig. 3, then a discharge passing between F and T will jump across the air-gap separating the coils S, A, etc., rather than pass around the coils themselves.

It is this principle which led to the early use of the arrangement shown in Fig. 4; this consists of a metal cylinder O, around which a coil C is wound, this coil being insulated from O by means of a fiber or mica; one end N of this coil being connected to a line wire, and the other end U to the instrument to be protected. The cylinder is grounded at G. When a discharge passes through this arrangement it will jump from the layers of the coil to the cylinder, thus passing to ground.

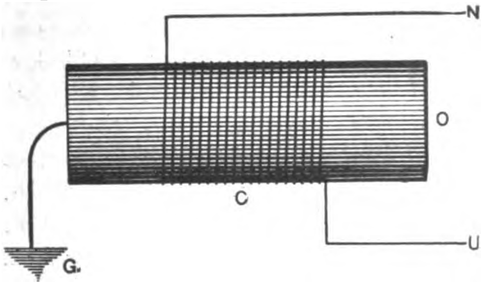

FIG. 4.

On account of the high resistance offered to a discharge by an inductive conducting medium it is evident that the arrangement shown in Fig. 5, which is often used in setting up telephones, is dangerous. The wireman, in installing a telephone, usually forms helices at the ends of the wires, which connect to the instrument and ground, these being formed of a number of turns. Connected to the binding posts H, A and S of the telephone E, are the ends of the coils F, T and Y. It is evident that such an arrangement offers a great resistance to an incoming lightning discharge, and prevents, in a great measure, its escaping to the ground by the required path.

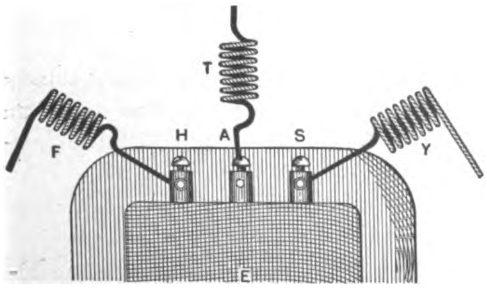

FIG. 5.

The disadvantage of an arrester formed of carbon blocks separated by a piece of paper or mica, is the fact that a heavy discharge is liable to produce a carbonization of the paper and thus connect electrically the two blocks, which connect the instrument to the ground. This action is shown in Fig. 6, which gives a section of a paper sheet that has been thus punctured. While a comparatively large amount of equidistant discharging area will prevent in a great measure this action, it is usually best after a severe lightning storm to replace the separating medium in such arresters as have been in operation.

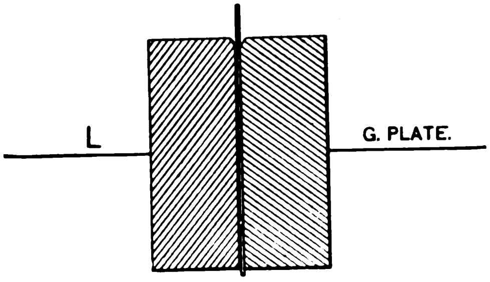

FIG. 6.

An arrester that works successfully on telegraph or signal line would not necessarily be practicable for application to a telephone. For this reason special appliances are employed, which, while seemingly flimsy and makeshift from a construction point of view, are capable of performing their work well.

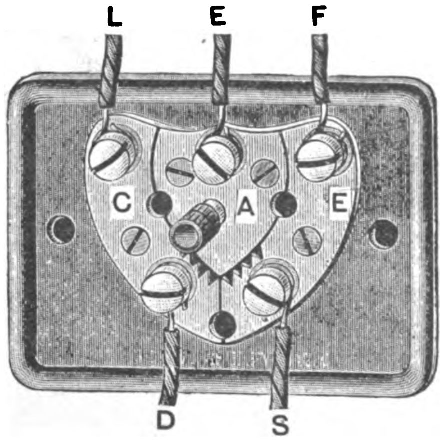

FIG. 7.

A good telephone arrester will fulfill the following conditions—first, be economical in construction; second, be of small size and pleasing appearance; third, offer the best possible path to ground for a high potential discharge.

Although brass plates, either separated by mica or paper, or provided with points, have been used very largely in arrester construction, long practice has shown that carbon, separated by a thin sheet of special paper is to be preferred. The necessary construction and consequent cost are reduced by this substitution, with perhaps an increase in efficiency.

When carbon is oxidized, the resulting compound, CO_2, is a gas, which readily passes off, leaving the oxidized surface in a better condition than before. The similar oxidation of metals on the other hand is liable to result in fusing the plates together. This, and the higher cost of the metals, has argued against their use.

Arresters for telephone purposes are used at the central office for every line and also at each instrument. With long lines it is frequently necessary to include intermediate arresters. They are also used at sub-stations and line junctions. It will be thus seen that a large number are used even on a small system. This renders imperative the use of a device that takes up but little space.

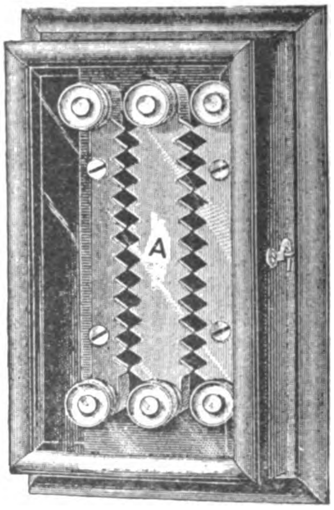

FIG. 8.

The simplest arrester made, but doubtless the most inefficient, is known as the saw-tooth arrester, two forms of which are shown in Figs. 7 and 8. Describing that shown in Fig. 7, we have: Upon a suitable insulating base are mounted the brass plates C, A and E, these being of the form shown. Connected to these outer parts are the line wires L and F and the instrument wires D and S. The plate A is connected to ground by the wire E. Plates C and E are provided with points or saw teeth, the purpose of which is to allow the high potential discharges to pass to the earth.

It is a well-known fact that static electricity passes more readily from a point to a plate than from a plate to a plate, hence the object of this construction. This arrester is also provided with a plug, by means of which the instrument may be cut out, leaving the line continuous. This feature is especially valuable for series party lines. The plug may also be used to connect either line to ground.

In Fig. 8 a modified form of saw-tooth

arrester is shown, The ground plate A, centrally located, is provided on both sides with teeth. This device was formerly used for telephones that are "bunched."

(*To be continued.*)

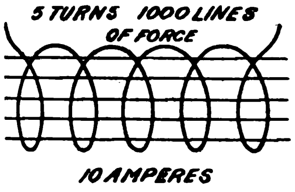
ELECTRICITY LEAFLETS.

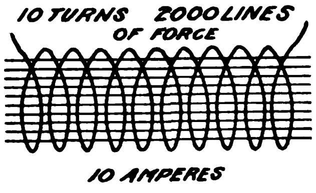
BY NEWTON HARRISON, E. E.

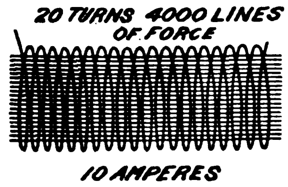
ELECTRO-MAGNETISM.

Laws of Electro-Magnetism.—In practical work it is possible to calculate with the greatest accuracy results in electro-magnetism by using a simple law embracing all of its applications. In order to fully grasp the idea it represents it is necessary to know the meaning of the constituents by which it is presented for practical use and through which the relationship between the parts of an electro-magnetic circuit are best understood.

Magneto-motive Force.—The electromagnet consists of a coil of wire carrying a current and either possessing a core of iron or not as the circumstances require. It is easy to see that the production of magnetism depends upon the number of loops of wire carrying a current. It is also evident that not only are the number of loops to be considered but the strength of current they carry as well. Here, then, is the point involved: That the greater the number of turns or loops of wire and the greater the current in these turns the greater the magnetic effect produced in total.







Ampere Turns.—It is customary to speak of the loops of wire as turns and the combination of current and turns as *ampere turns.* From a purely physical standpoint the "magnetism producing" elements of an electro-magnet are the ampere turns. These are obtained by multiplying the turns of wire composing the magnet by the amperes passing through, the total representing ampere turns. For instance, if an electro-magnet consists of 1,000 turns carrying a current of 10 amperes, the ampere turns = 10 × 1,000 = 10,000 ampere turns. If the turns are 1,000 and the current $\frac{1}{10}$ of an ampere then the product = $\frac{1}{10}$ × 1,000 = 100 ampere turns. But the case may be slightly different if, for example, there are 10,000 turns and 1 ampere or 1 turn and 10,000 amperes. In either case the total ampere turns = 10,000 which means that the *magneto-motive force* is the same.

In calculating the magneto-motive force the ampere turns are multiplied by 4π giving as the complete value $4\pi n c$ where π 3.1416, n = turns, c = amperes. For instance, the magneto-motive force of a coil of 1,000 turns carrying 10 amperes is equal to 4 × 3.1416 × 10 × 1,000, = 125,664. If the current is reduced the magneto-motive force reduces correspondingly, and the power of the coil to force magnetism through an iron bar is also reduced.

The idea, therefore, associated with magneto-motive force is the power of the ampere turns to force magnetism at a certain strength through a bar of iron. If the bar is long it would require more magneto-motive force to produce a certain number of lines of force throughout than if the bar is short. In other words, the dimensions of the iron bar, its length, breadth and thickness, will have to be considered in conjunction with the magneto-motive force in order to arrive at a clear and adequate idea of the conditions governing the development of a magnetic field produced by electro-magnetism.

Law of Electro-magnetism.—The law of electro-magnetism states that "the magnetic flux is directly proportional to the magneto-motive force and inversely proportional to the magnetic reluctance." This can be represented in the following form:

$$\text{Magnetic Flux} = \frac{\text{Magneto-motive Force}}{\text{Magnetic Reluctance}}$$

The magnetic flux and reluctance will each be treated separately and will be found to represent respectively, first, the number of lines of force produced, and, secondly, the conditions through which the magneto-motive force must operate to produce the magnetic flux; said conditions consisting of the dimensions of the space or material through which the magnetism is being produced and the permeability of the material magnetized.

Magnetic Reluctance.—The reluctance of the material to be magnetized calls for a greater or less magneto-motive force to produce a given magnetic flux, the same as the greater the resistance of an electric circuit the greater the electro-motive force required to send through it a current of given strength. The reluctance of any magnetic circuit must consist of four items, three of which are dimensions and the fourth is a native peculiarity of the material called permeability. The dimensions are naturally the length, breadth and thickness or the length and cross-section of the material undergoing magnetization.

Permeability.—Permeability is sometimes called the ratio between the lines of force in iron and the lines of force in air.

$$\text{Permeability of Iron} = \frac{\text{Lines of force in a magnetized bar}}{\text{lines of force without iron}}$$

For instance, if the magneto-motive force of a coil carrying a certain current produces 10,000 lines of force in air, which when a bar of iron is inserted increase to 10,000,000, then the permeability or multiplying power of the iron can be represented by the ratio of 10,000,000 to 10,000, or permeability = 10,000,000 ÷ 10,000 = 1,000.

Many cases can be cited to illustrate the meaning of permeability in iron, steel or air which would disclose the fact that in the softer grades of iron like wrought iron and mild steel the permeability is higher than in cast iron or any of its modifications.

Air as a Standard of Permeability.—Air is taken as a standard of permeability and is called 1. In comparison the magnetizable metals rate very high and range according to the following schedule as regards their permeability:

Air	1
Cast Iron	800
Mild Steel	2,000
Wrought Iron	3,000

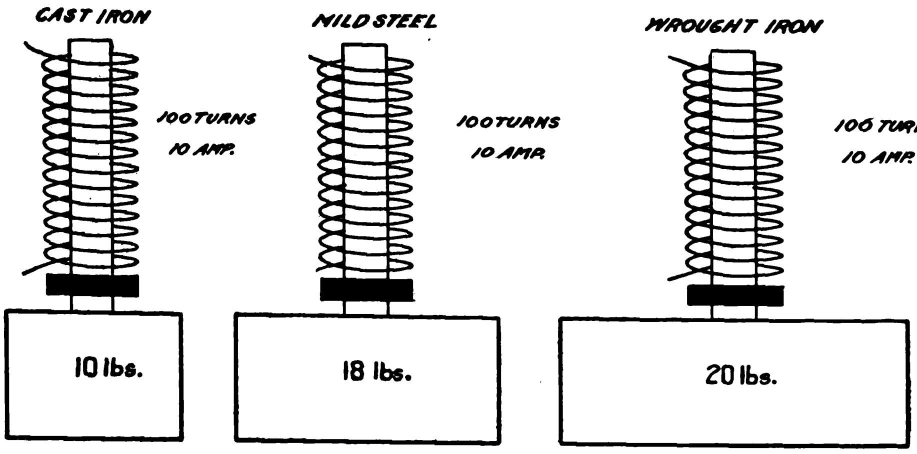
The result of a lower permeability is less lines of force when the same magnetizing force is employed by means of a coil.

This idea can be well represented by making three bars of cast, wrought iron and steel of exactly the same dimensions and placing them in three coils of the same number of turns and supplied with exactly the same current apiece. This would give the same magneto-motive force to each coil and the same dimensions to each magnetizable bar; the only difference would be found in the different permeabilities of the metals respectively.

The law that the magnetic flux is proportional to the magneto-motive force and inversely proportional to the reluct ance can now be represented symbolically as follows:

$$F = \frac{\text{M. M. F.}}{\text{R}}$$

Where F = flux, M M F = magneto-motive force and R = reluctance. If the magneto-motive force can be represented by 4π n c and the permeability is represented by the Greek character μ, then the flux can be calculated by the following formula which presents exactly the same proposition but has given a symbol, and a value in consequence, to all the elements which compose a problem in electro-magnetism:



$$\text{Lines of force} = \frac{4 \times \pi \times \text{n} \times \text{c} \times \mu \times \text{q}}{10 \times \text{l}}$$

Where 4π n c = magneto-motive force.
μ = permeability.
q = cross section of iron in square centimeters.
l = length of iron in centimeters.

To show the application of the formula suppose a coil has 500 turns and carries 2 amperes. The iron has 10 square centimeters cross section and is 20 centimeters long with a permeability at that point of magnetization of 1,000; how many lines of force will be produced?

$$\text{Lines of force} = \frac{4 \times 3.1416 \times 500 \times 2 \times 1{,}000 \times 10}{10 \times 20}$$

Lines of force = 628,320.

The formula can be transformed to suit the requirements of the English system by calling every centimeter .4 of an inch, or 1 inch = 2.5 centimeters, and every square inch equal to 6.25 square centimeters.

If the formula is carefully examined it will be found to consist of 4π n c, the magneto-motive force and permeability and cross-section in the numerator. If these symbols are placed below in the denominator the formula would appear in this form:

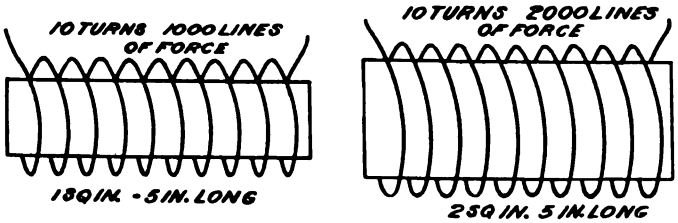
$$\text{Lines of force} = \frac{4\pi \text{ n c}}{10\left(\frac{1}{\mu \text{q}}\right)}$$

Here the μ and q have been placed below to constitute what is called the reluctance, thus giving as the elements of the formula:

Magneto-motive force = 4π n c

$$\text{Reluctance} = \frac{\text{l}}{\mu \text{ q}}$$

The 10 is there to reduce amperes into absolute units of current which are equal to 10 amperes. If 10 amperes were employed in the coil only 1 absolute unit of current would appear in the formula. The reluctance consists of the dimensions l and q and the permeability μ. If the reluctance becomes less, the lines of force will increase with the magneto-motive force remaining the same. If the reluctance increases, the lines of force diminish if the magneto-motive force remains the same. If the formula for the reluctance is examined it will be found that the reluctance can only be increased by increasing l or the length of the magnetic circuit or decreasing μ or q the permeability and cross-section of the circuit. On the other hand, the formula given as below shows that a great magnetic reluctance can be compensated for by increasing the magneto-motive force :



EFFECT OF REDUCED RELUCTANCE.

$$\text{Lines of force} = \frac{12.57 \times \text{turns} \times \text{amperes} \times \text{permeability} \times \text{cross-section}}{10 \times \text{length of magnetic circuit}}$$

$$= \frac{1.257 \times \text{ampere turns}}{\text{reluctance.}}$$

This simple formula shows that the lines of force produced by a given magneto-motive force will increase or decrease according to the reluctance. In a given coil in which various bars of iron and steel are inserted of equal size, the lines of force produced in each case with a constant current in the coil will depend upon the respective reluctances of the bars.

THE CONICAL WIND MOTOR.*

BY DR. ALFRED GRADENWITZ.

The Danish Government has for a number of years paid much attention to the problem of utilizing the power of wind, and Prof. La Cour has been entrusted with the conduct of systematic experiments in that direction in an experimental mill built expressly for the purpose, in the neighborhood of the town of Askov. Now, some years ago, Mr. Sorensen, a mill engineer, submitted to the Danish professor a wooden wind motor of his own construction, which had shown quite a surprising performance, as, four of the 10 sails of the motor having been broken by a storm, the mill, far from being damaged, worked more satisfactorily than before. This fact showed that the ancient principle, according to which the amount of power gained would be the higher the greater the surface, was false, and further experiments by Prof. La Cour go to bear out this conclusion.

Mr. Sorensen, with the aid of the experience thus gained, improved his motor, and eventually supplied the experimental mill with some wind motor models of a conical shape, having six wings with their points bent forward, the surface area, inclination of wing points and inclination of the wheel shaft being determined according to certain principles. Two types were subsequently tested jointly with eight other wind motors of all the current patterns, including motors with wings both narrow and broad, hollow and level, more or less numerous, and of varying inclination, but all of which had the same diameter as the conical wind motors. The results of some of these comparative tests are shown below, and the shapes of some of the motors are also indicated:

	Fig. 1. Ventotrat.	Fig. 2. Wind-rose.	Fig. 3. Sorensen's old motor	Fig. 4. Conical wind motor.
Area. sq. cm.........	7,440	2,976	1,116	1,188
Output, kgm. sec.	1.59	1.77	1.81	2.34

It is hence inferred that conical wind

---

*From the "Electrical Review," London.

motors will give an output nearly 50 per cent. higher than a ventotrat, which is seven times greater, 33⅓ per cent. higher than a wind-rose of 2.8 times greater surface, and 29 per cent. higher than the original Sorensen motor, which was only 7 per cent. smaller. This extraordinary power of conical wind motors may thus be accounted for: The main force of the wind will be applied to the paddle-shaped extremities, the parts most effective in producing torque; while, on the other hand, the wind will be allowed to pass between the wings, thus carrying along the air behind the latter and reducing the back pressure.

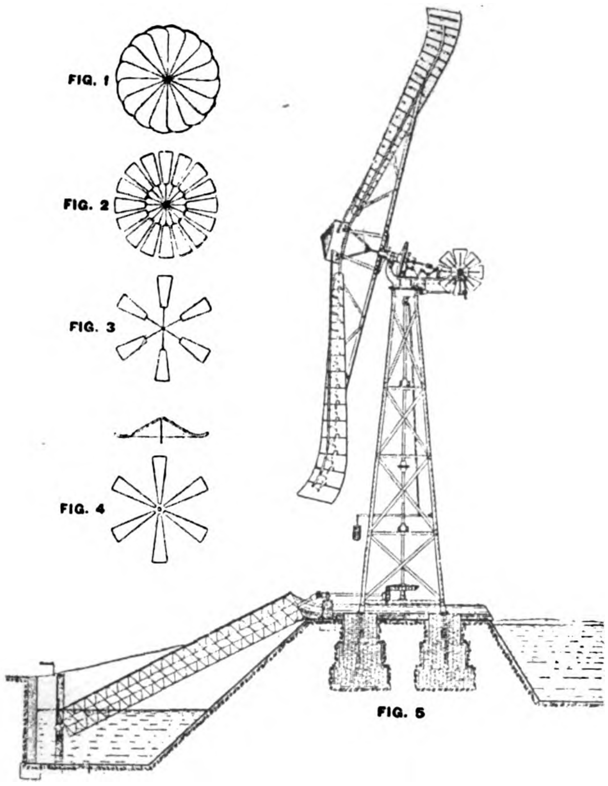


Fig. 5.—Waterworks, with 15 hp. Conical Wind Motor.

That the wind acts on a perforated surface with a power much greater than in the case of an equal surface closed throughout, is borne out by the following experiment: Two plank fences of the same thickness and height, one of which had intervals between the planks, while the other was compact, were submitted to the action of the wind, when the open fence was thrown down, though the compact fence obviously opposed the greater surface to the wind. A further fact known in this connection is that perforated sails will work more satisfactorily than those free from any holes, and this has been utilized in a recent Italian invention.

A further feature of conical motors is their safety against storms. Conical forms are mechanically strong, and the conical shape allows of a far more efficient construction, mechanically; moreover, the area exposed to sudden blasts is quite immaterial in the case of conical wind motors. In the state of rest, the motor is left with the sections wholly opened, as in Fig. 7.

Another feature, i. e., the automatic regulation of the motor, will prove of the highest importance. This regulation is effected by the swivelling boards of the wings being opened by their centrifugal force, when the speed of rotation exceeds a prearranged amount, thus allowing the surplus wind to pass through. As soon as the wind slackens down, the motor rotates at a slower rate, the centrifugal force of the boards will no longer keep them open, and a counterweight draws them together automatically. The regulation according to the direction of the wind, i. e., the steering of the motor, also takes place automatically. In smaller types (up to 6 hp.) this is done wholly by means of a weather flag, which, being thrown by the wind into its direction, will at any time turn the motor towards the wind. For the larger types of motor a wind-rose is used instead, adjusting the wing wheel to the wind by means of worm gearing. Motors intermediate between 6 and 15 hp. may be fitted either with a flag or with a wind-rose.

Apart from the above steering flag, which is made of wood, the conical wind motor consists wholly of iron and steel, even the wind-rose being made of iron.

Conical wind motors are in many cases used in the place of a steam engine. Pumps, wood and iron-working shops and agricultural and milling plants may be operated by these wind motors, which do not require any appreciable amount of supervision; they may also be used for generating electricity. For the latter purpose, the firm of Theodor Reuter & Schumann, of Kiel, Germany, who are the manufacturers of the motors, have designed a very simple apparatus for regulating the speed of the gearing driven from the wind motor with absolute accuracy, as required by a dynamo. Another device enables a wind motor and a steam engine to work jointly on the same transmission, when the wind motor serves to relieve the steam engine, thus securing a considerable saving of coal. In the event of the intensity of the wind decreasing so that the wind motor cannot keep up to the speed of the steam engine, another device will throw it out automatically

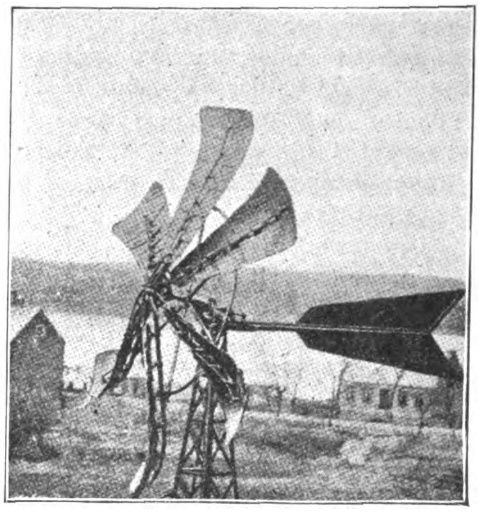

Fig. 6.—Conical Wind Motor, with Wings Closed.

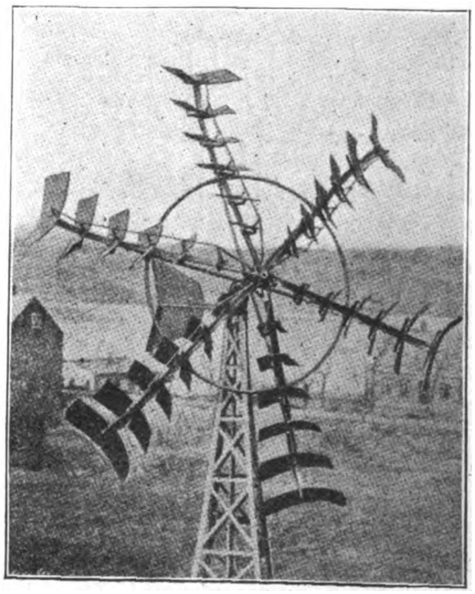

Fig. 7.—Conical Wind Motor, with Wings Open.

during the time of low wind intensity; the steam engine never has to turn the wind motor round.

FOG-DISPELLING APPARATUS.*

Sir Oliver J. Lodge has been granted a patent in England (No. 24,305 of 1903), entitled, "Improvements in means for the production of continuous high potential electrical discharges applicable for the deposition of dust, fume, smoke, fog and mist, for the production of rain and for other purposes," of which the following is an abstract:

The property of the electric discharge of causing the coalescent deposit of matters suspended in a gaseous medium has not come into practical use on account of the difficulties attendant on the use of the statical electrical apparatus, this class of apparatus being too delicate and easily upset for use on an extensive scale. Sir Oliver Lodge's invention consists in a combination of high potential rectifiers, arranged in quadrilateral groups of four or multiples of four in such a way that instead of the reverse pulses of the alternating-current supply being suppressed or non-existent as at present they are redressed to form the positive and negative discharging streams required for the deposit purposes.

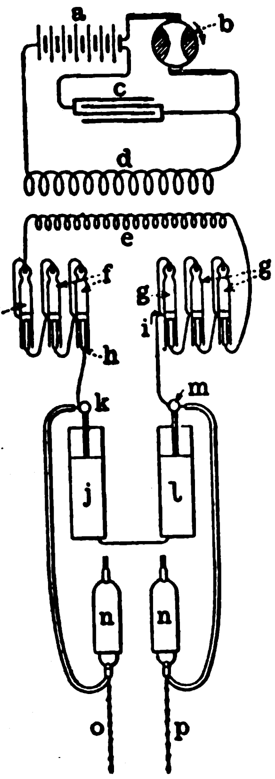

FIG. 1.

Referring to the accompanying drawings: Fig. 1 is a diagrammatic view showing one method of carrying the invention into effect; Fig. 2 shows diagrammatically another method in which an alternating-current dynamo is used; Fig. 3 is a view of a rectifier suitable for use in carrying out the invention, while Figs. 4 and 5 show some of the means of insulation which may be employed.

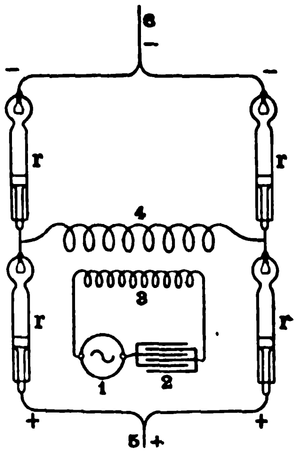

FIG. 2.

In the arrangement shown in Fig. 1, is a battery in circuit with an intermitter, b. and the primary d, of a large Rhumkorff induction coil; a condenser, c, may be placed in placed in parallel with the intermitter b. The secondary e of the Rhumkorff coil is connected through two series of high potential rectifiers, f g, preferably of the form hereinafter described in the terminals k m, of the insulated coatings of a pair of Leyden jars, whose outer coatings, j l, are in electrical connection. To the terminals k m are also attached the leads for discharging wires, o p, which are supported by insulators, n. A dynamo may be employed in place of the battery. The leads or discharging wires must be well insulated (see Figs. 4 and 5). The discharges may be points, flames, or other means whereby a free discharge can be obtained; parallel rows of barbed wire or of barbed wire fencing or other metallic areas may be used, one of which areas may be insulated while the other is earthed, or both may be insulated and placed facing each other beyond sparking distance in the place where the discharge is wanted. When the apparatus is used for the removal of smoke or the like, it is preferable to insulate both dischargers; when the electrification of clouds is the object, one set of dischargers would usually be earthed, and the other set arranged so as to be discharged skywards by well-insulated conductors.

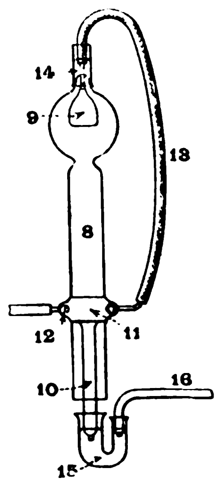

FIG. 3.

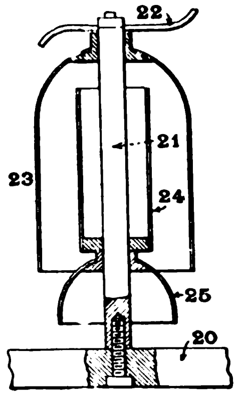

FIG. 4.

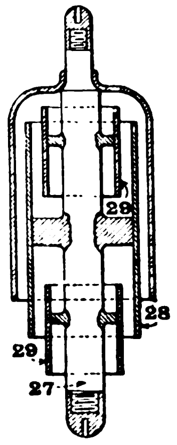

FIG. 5.

In the operation of the apparatus the current generated in the battery or dynamo is interrupted by the intermitter and induces intermittent pulses of violently high potential in the secondary coil of the Rhumkorff coil; these pulses are transmitted through the rectifiers, positive pulses through the series f and negative pulses through the series g, to the insulated coats of the two Leyden jars. The object of each series of rectifiers is to transmit a current easily in one direction and to strongly oppose a passage of current in the opposite direction; by this means the intermittent supply from the induction coil is enabled to maintain the jar or jars steadily charged. The higher the potential desired the more numerous are the rectifiers required in each series, and it has been found that three in each series is a convenient number to use where it is required to keep up a practically continuous discharge, between the dischargers, at a potential of about a quarter of a million volts.

Fig. 2 shows an arrangement in which the source of current is an alternating current dynamo; the dynamo 1 is placed in circuit with a condenser, 2, and the primary, 3, of an alternating current transformer which may, in this case, have a closed magnetic circuit. The high potential rectifiers, r, arranged in a quadrilateral, are combined in four groups, each of which contains one or more rectifiers in series, the number depending on the potential required. Two of the groups of rectifiers similarly directed are connected between the terminals of the secondary coil, 4, and the positive discharging means, 5, and the other two, both directed in the opposite direction, are connected between the terminals of the coil 4 and the negative discharging means, 6. In this arrangement an alternating current dynamo may be used, having an excessively high frequency, say, 3,000 to 4,000 alternations per second, or the alternating discharge of condensers such as Leyden jars may be employed.

---

*From the "Electrician," London.

In this case, as in the arrangement shown in Fig. 1, Leyden jars may be connected between the rectifiers and discharging means thereby obtaining a more continuous discharge.

The rectifier shown in Fig. 3 is similar to the Cooper-Hewitt mercury vapor lamps, and is formed from thick glass tube, 8, having an iron anode, 9, at the top and provided at the bottom with a mercury-pool cathode, 10, surrounded by an outside metallic band, 11; the positive terminal 12 is formed on this band which is connected to the anode, 9, by an insulated wire, 13, the contact being made by placing the end of the wire 13 in a vessel, 14, containing mercury formed at the top of the tube 8. A U-tube 15 containing mercury is placed so that the contact leading from the mercury pool is under the surface of the mercury in the U-tube as is also the end of the wire 16 leading from the cathode. The object of the mercury contacts 14 and 15 is to avoid the loss which would otherwise occur at the exposed points on the conductors, when used to convey electricity at the high potential necessary. In some cases the rectifiers may be submerged in oil in order to lessen the liability to loss and spitting off, but this is not usually found to be necessary.

In Fig. 4 the conductor 22 is supported on an ebonite or glass or earthenware rod or other suitable insulator, 21, from a supporting beam, 20; the rod is protected by two umbrella-shaped inverted covers 23 and 25, and a cylindrical vessel 24 open at the top, all of which are constructed of ebonite, earthenware, glass, mica or other suitable material. Fig. 5 shows a modification in which the conductor is suspended from a rod, 27, protected by cylindrical vessels, 28, 29, all being constructed of suitable insulating material.

The apparatus described may also be used for causing the deposit of lead fume in the manufacture of white lead by furnace processes or for depositing valuable factory dust.

The principal claims are:

(1) The method of causing small particles to coalesce into larger ones by the use of a high potential discharge, the supply of electricity being obtained from a dynamo or battery, or from the alternating discharge of condensers. (2) The method of causing small particles to coalesce into larger ones by the use of a high potential discharge obtained by the use of high potential mercury rectifiers and a high potential intermittent or alternating electric current. (3) The method of producing a continuous high potential discharge of electricity in one direction by the use of high potential mercury rectifiers so arranged as to transmit pulses always in one direction and so to charge and keep charged condensers which are connected to the discharging means, substantially as described.

HIGH FREQUENCY ALTERNATOR.

(From our London Correspondent.)

Mr. W. Duddell, of oscillograph fame, gave a description and demonstration of a high frequency alternator which he constructed four years ago for some experiments on the resistance of the electric arc before a recent meeting of the London Physical Society. With this alternator, which consists of an inductor built up out of ferrotype plate having V-shaped notches cut in its edge, so as to have flat-topped teeth, Mr. Duddell obtained frequencies up to 120,000 cycles per second.

Surrounding the inductor is a laminated ring having two inwardly projecting poles, the clearance between these and the teeth of the inductor, which formed the air-gap, being less than 0.1 mm. The ring is wound so that a direct current flowing round the winding tends to produce lines of force from one pole to the other through the inductor. The number of lines of force varies from a maximum when the teeth of the inductor are opposite the poles, to a minimum when the poles are in front of the spaces. This variation in the total number of lines of force produces alternating EMF's. in any winding either on the pole pieces or on the ring itself, the movement of the inductor through the distance between two consecutive teeth producing one complete period. One winding on the ring could serve to carry both the direct field current which magnetizes the ring and the alternating current produced. In practice, owing to the great importance of any self-induction in the alternating current circuit, it was found advisable at high frequencies to use separate windings for the two currents. At the highest frequencies the best results were obtained with coils having a few turns of wire fixed right on the tips of the poles. The alternator is driven by means of a figure-of-8 belt drive from two phosphor bronze disks. Each of these disks is belted to a double-grooved pulley fixed on the shaft of a direct current driving motor. With this method of drive the inductor was run for several months at speeds between 30,000 and 40,000 revolutions per minute, and the spindle of the inductor alone could be easily run at 60,000 revolutions per minute.

Using inductors having 30, 60, 90 and 204 teeth, the author obtains small alternating currents having frequencies from a few hundred periods per second up to 120,000 cycles per second. An illustration will perhaps convey some idea of how high a frequency of 120,000 cycles per second really is. In plotting curves for ordinary frequencies of 50 to 100 cycles per second, a scale often adopted is 10 inches for 100 cycles. If it were attempted to plot a curve up to 120,000 cycles per second to this scale, the curve paper would require to be 120,000 inches, or nearly one-fifth of a mile long. Many difficulties were encountered with the centrifugal forces on the driving-belt, and the author finally obtained the best results with a spliced cotton cord.

Prof. J. A. Fleming, in the course of the discussion which followed, expressed surprise that Duddell had been able to reach so high a frequency; it spoke highly of the excellent means employed. The difficulty with most high frequency alternators was the magnetic leakage. So far as wireless telegraphy was concerned the professor remarked that it was no use to speak of a machine even if it gave the frequency mentioned, corresponding to a wave of 1½ miles in length, if its output were only a few watts. If it were 150 hp. it might be different.

SEWAGE PURIFICATION BY ELECTRICITY.

Is electricity to include in the list of its marvelous achievements the solution of the great problem of sewage purification? A great deal has been heard, especially since the appointment of the Royal Commission on Sewage Disposal, says an English paper, as to the bacteriological treatment of sewage, and electrical methods have given results so encouraging that no surprise will be felt that it is an electrical process which has produced what seems to be a perfect purifier, cleanser and sterilizer. The opinion expressed by a number of sanitary scientists and others, less skilled, perhaps, although not less interested in the problem, who visited the Guildford Sewage Works the other day, was that the solution which is the agent employed in the oxychloride sewage process is a potent deodorant and germicide, adaptable with equal success for sewage purification, for household disinfection, and for general cleansing and bleaching purposes.

The process by which this purifying agent is produced is simple, and the necessary plant inexpensive. It consists in the electrical decomposition of salt and water, or, where easily obtainable, sea water in a specially designed electrolyzer having a large superficial area of electrical surface, which permits of the use of a large volume of current at a very low voltage, thus securing economy of operation. The solution thus obtained is added to the effluent in quantities varying according to its nature and the water into which it has to be discharged.

To demonstrate the commercial application of the process to sewage purification, Dr. Rideal, the well known expert, has made a series of experiments, extending over several months, in specially constructed tanks at the Guildford Sewage Works, the authorities having given every facility for the most thorough tests. To the visitors Dr. Rideal explained that at Guildford every kind of effluent could be dealt with, and tests had been carried out with raw sewage septic tank effluents and those from primary, secondary, and tertiary filters, and the efficiency of the solution in removing putrefactive organisms, the organisms which are comparable in origin and vitality with those which cause typhoid fever and cholera, and organic matter in solution had been demonstrated. To the public the interest lies not in the process, but in its results, and these suggest that in the treatment of raw sewage, or that which had undergone preliminary treatment in a septic tank, the solution has an effect, immediate and potent. To produce a purity from bacteria equal to or better than that generally allowed for drinking water was found not to be a difficult matter. With a primary effluent, 7½ gallons of oxychloride per 1,000 gallons of effluent reduced the bacillus coli—present in all sewages, and allied to the typhoid bacillus—and the enteritis spores from over 100,000 and 100 respectively, so that none could be found in one cubic centimeter in 1 hour 20 minutes after treatment. In raw sewage, 18½ gallons per 1,000 reduced the coli from over 1,000,000, so that none were found in one cubic centimeter, and the enteritis spores from over 1,000 to less than ten in 5 hours, and the total number of organisms from 23,200,000 to 540.

The Annual Scientists' Meeting.

Over 1,500 scientists of the United States were in attendance at the annual meeting of the American Association for the Advancement of Science and of the American Physical Society held in Philadelphia, during "Convocation Week," from December 26 to January 2. The presiding officers were W. F. Magie, the vice-president of Section B, and Prof. Arthur C. Webster, president of the American Physical Society.

Hon. Carroll D. Wright retired from the presidency of the association and was succeeded by Prof. W. G. Farlow of Harvard.

Among the many papers read were the following:

"Experimental Study of the Use of Weston Instruments for Ballistic Magnetic Testing," Alb. F. Ganz, Stevens Institute of Technology,

"Explanation and Demonstration of the Poulsen Telegraphone," Z. B. Babbitt, New York City.

"Electric Double Refraction in Liquids Under Low Electric Stress and also at at the Boiling Point," D. B. Brace, G. W. Elmen and L. B. Morse, University of Nebraska.

"The Electromagnetic Theory and the Velocity of Light," Henry T. Eddy, University of Minnesota.

"The Distribution of Energy in the Visible Spectrum," Edward L. Nichols, Cornell University.

"Objective Method for Showing Distribution of Nuclei Produced by X-rays or other Radiation," C. Barus, Brown University.

"Experiments on Resonance in Wireless Telegraph Circuits," G. W. Pierce, Harvard University.

"The Ratio of Electrical to Gravitational Forces," Bergen Davis, Columbia University.

"A Measurement of the Thomson Thermo-electric Effect in Iron," Edwin H. Hall, Harvard University.

"A Contribution to the Theory of Thermo-electromotive Force," C. B. Thwing, Syracuse University.

"New Phenomena of Fluorescence," Harry W. Morse, Harvard University.

"The Tuning of Thermo-electric Receivers for Electric Waves," A. D. Cole, Ohio State University.

◆

The Norwegian steamer Atlas reports that on her trip up the coast from the West Indies the electric beam that is thrown skyward from the deck of the Diamond Shoals Lightship was visible for 24 miles. The longest distance previously reported at which the beam was seen is 21 miles.

The Paris Automobile Exhibition.

On Friday, December 2, the great motor exhibition at the Grand Palais in the Champs Elysees was opened by President Loubet. The exhibition is of a representative character, but there are no striking innovations. The exhibition practically marks the disappearance of the tubular frame, the uninclosed type of radiator, and the atmospheric inlet valve. Even Renault and the De Dion firm, have come substantially into line in this respect. Panhard still retains the wood and flitch plate frame, and C.G.V. the square section wood-filled tube, but with these exceptions, every French maker has adopted the "chassis embouti," first introduced by the makers of the Mercedes. The conservative Panhard, however, still adheres to the atmospheric inlet valve on the 7 hp. and 10 hp. cars, and De Dion retains it on all models, but everywhere else the mechanically operated valve reigns supreme. Radiators are invariably inclosed, and generally cooled by one, or sometimes two fans. There is a distinct tendency to place the fan in the flywheel, and where the belt driven fan is retained, provision is generally made by means of a spring for keeping the belt at a constant tension.

Clutches are of many varieties, as heretofore, but the well-tried leather-covered cone type seems at least to be holding its own in popularity. The high-tension and low-tension systems of magnets are both increasing in favor, to the almost entire extinction of the old coil and accumulator method of ignition. In one or two cases the ignition lever has entirely disappeared. There is a slight tendency to place less reliance on the engine governor, and in many cases the depression of the clutch pedal throttles the motor; and in all the Mors cars the governor has been abolished altogether, thus following the established Wolseley practice. The methods of lubrication and filling petrol tanks show considerable improvement. Prominent among the British exhibits is that of the Hozier Engineering Company, which includes a 10-12 hp. two-cylinder car, fitted with an Astor engine built into a long frame. This car is an improved successor of that which the company successfully introduced last season.—"Electrical Engineer," London.

Major Squier's Wireless Discovery.

A press dispatch from San Francisco, January 1, says that a discovery of the greatest importance to wireless telegraphy and to the electrical and scientific world in general has just been announced here by Major George O. Squier, U. S.A., chief signal officer of the Department of California. In a report to the War Department, he says that ordinary trees are conductors and transmitters of wireless telegraph and kindred magnetic waves, and in proof of this he has received and sent wireless messages by merely connecting his apparatus to two nails driven in the trunk of a tree.

Major Squier drove two nails in a tree on the lawn of General MacArthur's quarters at Fort Mason, and by attaching a simple field wireless telegraph receiver to those nails, read all the messages that were passing between the naval wireless telegraph stations at Goat Island and Mare Island Navy Yards, many miles away.

10,000 hp. Dynamos Set in Motion.

The Canadian Niagara Falls Power Company, the ally of the American Niagara Falls Power Company, successfully set in motion on Monday two of their 10,000 hp. turbines and dynamos before the officers of the power company and distinguished guests.

These are the largest machines in the world, and their operation marks an electrical epoch. Francis Lynde Stetson, of New York, and President W. H. Beatty, of the Canadian Company, turned on the power.

Preparing the Question Box.

Mr. Homer E. Niesz, editor of the Question Box for the Denver-Colorado Springs meeting of the National Electric Light Association, has sent out over 7,000 letters to companies and individuals in the electrical field asking them to submit questions to be grouped under the following headings: A, Buildings; B, Water Wheels, Water Power, etc.; C, Feed Water, Heaters and Pumps; D, Fuel; E, Boilers and Mechanical Stokers; F, Forced Draft, Blowers, Stacks; G, Piping, Condensers, etc.; H, Engines; I, Turbines; J, District Heating; K, Generators and Exciters; L, Storage Batteries and Boosters; M, Switchboards, Instruments and Station Wiring; N, Belts and Shafting; O, Oil and Waste; P, Overhead Lines; Q, Underground Lines; R, Transformers; S, Lamps—Arc, Incandescent, etc; T, Heating, Battery Charging and Power; U, Meters; V, Advertising; W, Contracts and Rates; X, Accounting and Statistics; Y, Management; Z, Miscellaneous.

Mr. Niesz not only desires questions from those seeking information, but he appeals to the missionary spirit in those who have solved difficulties for themselves, and asks them to send questions to which they have found solutions together with the replies, for the benefit of others.

There is practically no limit to the benefits to be gained through this interchange of knowledge, and, if it were understood as it should be by central station companies not already members of the National Electric Light Association, they would lose no time in taking membership.

Proposals Invited.

The Navy Department, through the Bureau of Yards and Docks, is inviting sealed proposals until January 21, for furnishing a 20-panel switchboard for the Washington Navy Yard. Plans and specifications will be furnished by the commandant of the yard.

The Bureau of Supplies and Accounts of the Navy Department is inviting sealed proposals until January 24 for the installation of an electric lighting system, etc., at the U. S. Naval Training Station at Newport, R. I. Blank proposals will be furnished upon application to the bureau or to the navy pay office in Newport. On the same date the bureau will open bids for the installation of an electric lighting system, exterior underground conduit and cable, and fire alarm, call bell and telephone systems in and near the barracks building now under construction at the training station at Newport.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED DEC 27, 1904.

Electric Railways and Appliances

778,256. Electric Railway. Joseph dela Mar, New York City, assignor of one-half to Mathias A. Lazareff, same place. Filed March 8, 1904.

778,356. Railway-Signal. Frank L. Fuller and Charles S. Banghart, New York City. Filed March 21, 1904.

778,376. Trolley Harp and Guard. Stephen G. Reynolds, Easton, Pa., assignor of one-half to Nathan Freeman, same place. Filed June 29, 1903.

778,418 Railway Block-Signal System. Rector E. Land, Mount Washington, Mo. Filed April 25, 1904.

778,520. Trolley, John S. Weckman, Carnegie, Pa. Filed Sept. 22, 1904.

778,832. Electric Traction. Henry B. Greenwood, Buenos Ayres, Argentina. Filed July 16, 1904.

Electric Lights and Appliances.

778,280-281. Incandescent-Lamp Socket. Clarence C. Sibley, Perth Amboy, N. J., and George A. Lutz, New York City. Filed Nov. 24 and Dec. 11, 1902.

778.383. Incandescent-Electric-Light Socket. Luttrell H. Stuart, Chicago, Ill., assignor of one-half to Necter-Rousseau, Sr., same place. Filed Aug. 14, 1903.

778,489. Electric-Arc Lamp. Albert W. Hendricks, Pittsburg, Pa. Filed March 30, 1904.

778,602. Electric Lamp and Shade-Holder. Louis H. Perkins, Meriden, Conn., assignor to Edward Miller & Co., same place. Filed May 18, 1904.

778,618. Means for Supporting Electric Lamps and Energizing and Lighting Same. William H. Wilkinson, Boston, Mass. Filed April 29, 1904.

Electrical Machinery and Apparatus.

778,222. Automatic Current-Regulator for Electric Motors. Alexander Churchward, New York City, assignor to the General Electric Company. Filed July 16, 1903.

778,238. Electric Brake. Edwin R. Gill, New York City, assignor to the Invention Developing Company Fil 900

778.221. Apparatus for Producing High Vacuums. William R. Burrows, Newark, N. J., assignor to the General Electric Company Filed April 8, 1901.

778.242. Electrical Controlling Apparatus. George H. Hill, Glenridge, N. J., assignor to the Sprague Electric Company. Filed June 27, 1902.

778.333. Electric-Current Governor. Walter J. Richards, Milwaukee, Wis. Filed April 11, 1903.

778,400. Electric Motor. James H Bryson, St. Louis, Mo., assignor to the Wagner Electric Manufacturing Company, same place. Filed April 21, 1904.

778,531. Electric Fuse Switch-Box. Louis W. Downes, Providence, R. I., assignor to the D. & W. Fuse Company, same place. Filed May 20, 1904.

778,549. Apparatus for Transmitting Power at Varying Speeds. Walter F. Rice, Fitchburg, Mass. Filed July 20, 1903.

778.575. Quick-Break High-Tension Electric Switch. Henry K. Gardner, Providence, R. I. Filed Dec. 21, 1903.

778,681. Electrical Connector. Hubert Krantz and Ernest W. Muller, Brooklyn, N. Y., assignors to the H. Krantz Manufacturing Company, same place. Filed March 15 1904.

778,798. Frame for Electrical Machines. Francis A. Pocock, Lansdowne, Pa., assignor of three-eighths to Edward W. Patterson, Philadelphia, Pa. Filed Oct. 17, 1903.

778,825. System of Motor Control. George H. Hill, Schenectady, N. Y., assignor to the Sprague Electric Company. Original application filed June 27, 1902. Divided and this application filed July 25, 1904

Telephones and Telephone Apparatus

778,322. Telephone-Circuit John W. H. Maclagan Park Ridge, N. J. Filed June 23, 1900.

778,409. Telephone Apparatus. Oscar M. Fryman, St. Paul, Minn. Filed April 20, 1903.

778,448. Tablet-Holder for Telephones. John W. Currier, North Tro , Vt. Filed Aug. 9, 1904.

778,569. Supervisory Apparatus for Telephone Systems. William W. Dean, Chicago, Ill., assignor to the Western Electric Company. Filed July 7, 1902.

778,599. Telephone-Exchange Switchboard Apparatus. James L. McQuarrie, Chicago, Ill., assignor to the Western Electric Company. Filed Feb. 1, 1902.

Miscellaneous.

778,269. Process of Electric Welding. Adolf F. Rietzel, Lynn, Mass., assignor to the Thomson Electric Welding Company, same place. Original application filed Oct. 15, 1903. Divided and this application filed Feb. 6, 1904.

778,275. Adjustable Bolometer Detector for Electro-Magnetic Waves. Charles K. Salisbury, Lincoln Township, Blackhawk County, Ia. Filed April 22 1904.

778 286. Manipulation of Refractory Material. Elihu Thomson, Swampscott, Mass., assignor to the General Electric Company. Filed Aug 28, 1902.

778,297. Composite System Duplex-Telegraph Circuits. William E Athearn, New York City, assignor to the American Telephone & Telegraph Company. Filed May 13, 1904.

778,305 Coin Controlled Circuit Making and Breaking Apparatus for Phonographs. Arthur W. Cole, West Hoboken, N. J. Filed April 26, 1904.

778,308. Therapeutic Electrode. George H. Day and Frank J. Stein, Louisville, Ky. Filed July 13, 1904.

778,414. Electric Cigar Lighter. William P. Carstarphen, Jr., Denver, Col. Filed April 4, 1904.

778,560. Supporting and Shifting Battery for Automobiles Allan R. Whiting Orange, N. J. Filed Sept. 19, 1903

778,621. Electromechanical Vibratory Massage Apparatus. Charles Adams-Randall New York City, assignor to the Randall & Carey Vibral-Massage Machine Company. Filed Jan. 9, 1904.

778,653. Electric Battery. Arnold Gabrielson, Milwaukee, Wis., assignor of one-fourth to Ole H. Lee, same place. Filed July 21, 1904.

778,693. Electrical Outlet-Box. Ernest W. Muller, Brooklyn, N. Y., assignor to Hubert Krantz, sam place. Filed April 23, 1903.

778,714. Electric Compensator. Edmund O. Schwe tz Chicago, Ill., assignor of one-half John J. Schay same place Filed Dec. 14, 1903.

778,771. Electromechanical Apparatus for Vibratory Massage. Charles Adams-Randall, New York City, assignor to the Randall & Carey Vibral-Massage Machine Company. Filed Feb. 9, 1 04.

778,770. Thermostat. Albert Goldstein, New York City, and Horace E. Rice, Philadelphia Pa Filed May 23, 1903.

Design.

37,278. Incandescent Lamp. Albert H. lling, New York City, assignor t he Talmo ineering Com

THE TELEPHONE WORLD.

Over 100 Companies Now Operating in South Dakota.

That the telephone is well patronized by the people of South Dakota is shown by the increase in numbers of companies, year by year, as reported to the State Auditor. In 1900 there were 35 companies operating in the State with 2,908 miles of line. The 1904 report of the auditor shows 106 companies in the State, with 9,782 miles of line.

The increase has been greatest the past two years, as only 35 companies reported in 1900, with 37 in 1901, 47 in 1902, 73 in 1903 and 106 in 1904.

Considerable complaint has been made in regard to the excessive telephone rates charged by the Cumberland Company in New Orleans, La. The rate charged the city represents an increase from $24 to $126 for the same period. This is 525 per cent. increase in one year. An effort was made to enter into a contract with the city at the rate of $80 per annum, the ordinance passing the council, but being vetoed by Mayor Mehle, it failed.

Announcement was lately made in Chillicothe, Mo., of the sale of a half interest in the Chillicothe telephone exchange, owned by Dr. Arthur W. McArthur, of Kansas City, to W. H. Ellett, president of the People's Savings Bank of Chillicothe. The reported consideration was $14,000 for the half interest. W. B. Leach owns the other half. Mr. Ellett denies the report that he is acting as agent for the Bell Company in the purchase.

The business men of Apache, together with a large number of farmers between Apache and Anadarko, Okla., have reorganized a stock company to build a telephone line from Apache to Anadarko. The stock has been subscribed, and work will begin at once. O. W. Rogers is president, Arthur Dyer secretary, and M. Hester treasurer of the company.

The net output of the American Telephone & Telegraph Company for November was 63,988 instruments, a decrease of 678, as compared with the same month last year. The total number of instruments outstanding on November 30 was 4,408,177, as against 3,730,248 at the same date last year.

Eight Cambridge, Minn., citizens have incorporated a telephone company which is to have headquarters in that town, and be known as the Cambridge Telephone Company. The capital stock is placed at $50,000, and lines will be maintained in Isanti and surrounding counties.

The Auburn, Mo., Telephone Company has been incorporated with a capital stock of $35,000, by B. H. Ramsey, E. R. Conklin and F. W. Kelly.

The Riley County, Kan., Farmers' Telephone Company, recently incorporated with a capital of $2,600, has begun the construction of a rural line.

The Bergen County N. J., Telephone Company, capitalized at $5,000, has been incorporated by John T. Trumbull, Edward H. Hoos and Spencer Weart.

New England Company Reduces Telephone Rates.

The reduction in telephone rates by the New England Telephone & Telegraph Company in Boston, where it has no opposition, has raised the question as to the purpose and expediency of this action.

An official of the company says: "The main reason for reducing the telephone rate from 10 cents to 5 cents in the exchanges of Boston proper was to popularize the telephone. With this reduction it is our expectation to place an increased number of telephones in the smaller mercantile houses, the nickel-in-the-slot machine being the form of telephone to be generally installed.

"As the area affected by the reduction includes a large residential section, especially the Back Bay, it is anticipated many additional home telephones will be installed.

"For a short time the company will, of course, suffer a loss in revenue by the reduction but this loss will be far more than made up in a short time by the increased use of the telephone."

Telephone Company's Earnings.

The Northwestern Telephone Company of Minneapolis, Minn., has filed a statement with the State Auditor showing gross earnings of $984,834.51 for the year ending November 30, 1904. The company is to pay a 4 per cent. tax on this, which will amount to $29,545.03.

Stearns County, Minn., has another telephone concern known as the Commercial Telephone Company of Belgrade. The capital stock is placed at $50,000, and the following are the interested parties, all of Belgrade: T. J. Anderson, C. Borderding, John F. Chisholm, Alexander Ridgeway, M. J. Mickelson, K. S. Colbiorsen, A. J. Lindquist, C. M. Iverslie, John H. Romness and S. F. Strong

C. C. Haas, a wealthy farmer near Whitewood, S. D., is about to organize a company for the purpose of putting in a telephone line from the Belle Fourche River to Whitewood. He has already constructed two miles of private line. The line will benefit a large number of farmers who live between the river and Whitewood.

About 600 telephones were put out of service by a recent fire in Sioux City, and the Iowa Telephone Company sustains a loss of between $5,000 and $6,000, according to the estimate of Manager E. A. Clark. The cables and wires in the burned district were entirely destroyed.

The first rural telephone line to be put into operation in Herkimer County by the Central New York Telephone Company was lately opened. The line extends from the company's central office in Cohoes to Eatonbush.

The New York & New Jersey Telephone Company has declared a regular quarterly dividend of 1½ per cent., and an extra dividend of 1 per cent. payable January 16, to holders of record January 5.

W. A. Pixley has been appointed auditor of the Nebraska Telephone Company.

Free Toll Service in Richmond, Ind.

Upon the recent completion of its new switchboards, the Home Telephone Company of Richmond, Ind., gave its subscribers free long-distance telephone service over the United States Telephone Company's lines in its Ohio territory. The above territory includes practically all of Ohio and parts of Michigan, Pennsylvania and West Virginia. The company has just installed new and up-to-date toll switchboards and now has has entirely separate apartments for its long-distance business. The boards installed are the latest and best type, and place the company in excellent position to take care of its long-distance business, as neither money nor time was spared in its effort to make its toll system as perfect as possible. Work is now in progress on additional copper toll lines between Richmond and Indianapolis, which will materially improve the service and facilitate prompt handling of toll business going west.

The Utah Independent Telephone Company recently made an official proposition to the business men of Salt Lake City to eventually inaugurate a party-line service. The proposition was made in writing to the committee appointed at the citizens' meeting held some weeks ago. The proposition made by the Independent company is that it will reduce the price of its residence 'phone, individual line, unlimited service, full metallic service, from the present price of $2.50 a month to $2 a month, this price to be maintained until the company shall have 6,000 subscribers connected in Salt Lake City. After that time the subscriber shall have the alternative of continuing this service at $2.50 a month or going on a two-party line with unlimited service at $2 a month.

The State Treasurer of Minnesota has received $11,584.50 from the Twin City Telephone Company. The amount was paid as the 3 per cent. gross earnings tax on the company's earnings in that State. The gross earnings of the Twin City Company, as reported by its officers for the year ending November 30, were $386,150.

The Independent Telephone Company of Salamanca, N. Y., has completed the construction and equipment of three copper circuits to Buffalo via Gowanda. Direct service is thus established to all towns in the vicinity now reached by the Inter-Ocean Company.

The Farmers' Telephone Company of Wills Point, Tex., capitalized at $10,000, has been formed for the purpose of constructing telephone lines in Van Zandt County. The incorporators are J. F. Sallee, A. M. Herrin and John Z. Owens.

The Niagara County Home Telephone Company has made application to the common council of North Tonawanda, N. Y., for a franchise to distribute electricity for lighting, heating and power purposes, It will use its own pole lines for distributing cables.

The Home Telephone Company of Santa Monica, Cal., has been granted permission to place its wires underground.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Benwood, W. Va.—The Ohio Valley Electric Company of this city and McMechen, has been incorporated with a capital of $50,000 to construct and operate an electric light plant, etc.

Calgary, N. W. T.—By a vote of 422 to 46 the people of this place decided in favor of installing a municipal electric lighting plant.

Cayuga, Ind.—The matter of installing a city electric lighting system here was lately discussed, and a committee appointed which will inspect lighting plants in other towns and ascertain the cost.

Clarinda, Ia.—A special city election will be held January 18 to vote on the proposition of granting a franchise to the Lee Electric Light Company to erect an electric lighting plant.

Des Moines, Ia.—The city council has ordered more lights, both gas and electric, arc and incandescent, for the suburban residence district.

East Moline, Ill.—The residents of this city want electric lights in their homes.

Eureka, Cal.—The electric power plant of the Eureka Lighting Company was recently destroyed by fire. The loss is estimated at $30,000.

Gilt Edge, Mont.—M. J. Dignan is figuring on installing an electric light plant here.

Jacksonville, Tex.—F. K. Nance has purchased the plant of the Jacksonville Electric Company and will expend $5,000 in improvements.

Lebanon, Ind.—A franchise has been granted to the Citizens' Electric Light & Ice Company to light the streets and for commercial lighting. E. D. Connor, city clerk.

Little Rock, Ark.—A number of the business men of this city and St. Louis recently purchased the electric light plant of Camden, Ark.

Mansfield, Mass.—At a special town meeting it was voted to appropriate $1,900 for increase in the commercial departmnet of the electric lighting system, and light the town hall and library by electricity.

Marshalltown, Ia.—The Business Men's Association has under consideration the matter of installing an electric lighting plant.

Mattoon, Ill.—The city council will soon be asked for a franchise for another electric light and power plant.

Meridian, Miss.—C. H. Dabbs, E. Cahn and others have applied for a franchise to establish a plant for furnishing gas, electric lights and steam heat.

Mineral Wells, Tex.—The Mineral Wells Electric Light, Power & Heating Company has been incorporated with a capital of $50,000 by D. G. Galbraith and others.

Moline, Ill.—A reduction from 5 to 20 per cent. on present figures on incandescent lights will be put into effect by the People's Power Company, beginning February 1.

Montgomery, Ala.—D. P. West will erect an ice and electric light plant at the corner of Bibb and Moulton streets.

Moscow, Ida.—The city council has granted the Moscow Electric Light Company a franchise to operate its local plant for 25 years.

Norfolk, Neb.—The council has granted a franchise to the Sugar City Cereal Mills to install an electric light system in this city.

North Attleboro, Mass.—Owing to a demand for electricity for power and lighting, extensive improvements are to be asked for at the annual meeting of the voters in March.

Oshkosh, Wis.—It is stated that the Central Construction Company of this city is about to ask for a franchise to erect an electric lighting plant for commercial purposes.

Pitman Grove, N. J.--The plant of the Pitman, Clayton & Glassboro Electric Light Company was recently sold by the receiver, David C. Watkins, of Woodbury, to M. K. Treichler, of Philadelphia, for $20,000.

Reading, Pa.—An electric light plant is to be installed in the new Reading car shops at Newberry Junction.

Richmond, Va.—It is reported that E. W. Trafford has been engaged to prepare plans for an electric lighting plant. W. H. Thompson, city electrician.

Royse City, Tex.—It is reported that J. E. Pynter & Son, of Adairville, Ky., and others are interested in the erection of a flour mill and an electric lighting plant. The company will be organized as the Royse Milling & Light Company.

San Diego, Cal.—The electric lighting plant here was lately damaged by an accident to the engine.

Siloam Springs, Ark.—The Siloam Springs Railroad, Power & Light Company, recently incorporated, will build a railroad and erect an electric light plant for furnishing light and power. Its capital stock is $500,000. D. Zimmerman president.

Toledo. O.—Col. J. C. Bonner, J. C. Hallepleus and others, of this city, are at the head of a company formed to develop water power in New Mexico. The company expects to furnish electric light to Las Vegas, Santa Fe and Albuquerque.

Vidalia, Ga.—The Vidalia Water & Electric Light Company has been incorporated here.

Youngstown, O.—The special committee of the city council will recommend the issue of bonds to the amount of $100,000 to build a municipal electric light plant.

STREET RAILWAYS.

Keokuk, Ia.—The proposed electric railroad from this city to Saint Francisville will be put through soon.

Litchfield, Ill.—It is reported that a traction company is negotiating with the Chicago & Alton for the purchase of the Quincy, Carrollton & St. Louis Railroad, for the purpose of converting it into an electric line.

San Diego, Cal.—President E. S. Babcock, of the San Diego & LaJolla Railroad, announces that the road will be changed from a steam to an electric line and the service quadrupled. The necessary material has been ordered and work will shortly be commenced.

Spokane, Wash.—The Washington Water Power Company proposes to build an electric line to Silver Lake in connection with the Medical Lake system.

St. Paul, O.—A company has been organized to build the Hutchinson & Western Railway. It is proposed to build electric lines through at least four counties.

POWER PLANTS.

Canaan, Conn.--The Berkshire Power Company, which has been organized here with a capital stock of $240,000, will construct a dam and power house on the Housatonic River at North Canaan. Preliminary work has already been commenced and the undertaking will be pushed as rapidly as possible. Plans for the generation of a large volume of electric power to be distributed over a large area have been formulated.

Duluth, Minn.—Messrs. Tucker, Anthony & Co., of Boston, and Charles D. Barney & Co., New York and Philadelphia, make the announcement that they have formed a syndicate to supply the money for the development of the water power in the St. Louis River between this city and West Superior. It is proposed to develop more than 100,000 hp.

Marion, Ind.—The power plant owned by the Pittsburg-Columbia Oil Company was recently destroyed by fire, entailing a loss of $3.000. A new plant will be constructed.

Milwaukee. Wis.—The architect firm of H. C Koch & Co., has filed with the building inspector plans for a new power plant.

Muskegon, Mich.—The Grand Rapids & Muskegon Electric Power Company has been incorporated with a capital of $1,000,000, for the purpose of building dams across the Muskegon River at Big Rapids, to furnish cheap electrical power to this city, Grand Rapids, Big Rapids and small towns in Western Michigan.

Salida, Col.—Plans are practically complete for the erection of a big power plant at Arborville, on the south fork of the Arkansas River, 15 miles north of here. The work is being carried on by the Edison Electric Company of Salida. The enterprise will involve the expenditure of $75,000, and is backed by local capital. The plan is to furnish cheap electric power in this city.

BIDS WANTED.

Alameda, Cal.--The city trustees are in the market for a tandem compound engine and generator, with a capacity of 240 kilowatts, for the municipal light plant to cost $13,000.

Anadarko, Okla.—The council has advertised for bids, to be opened January 9, for the construction of a municipal electric lighting plant to cost about $10,000.

San Antonio, Tex.--Sealed proposals, in triplicate, will be received here and at the office of the quartermaster, Fort Logan H. Roots, Ark., until 11 o'clock A.M., January 30, for the construction of a brick administration building, including installation of plumbing, hot water heating and wiring for electric lighting at Fort Logan H. Roots, according to plans and specifications to be seen at this office and office of quartermaster, Fort Logan H. Roots, Ark. The United States reserves right to reject any or all bids, or any part thereof. Information furnished on application, Envelopes containing proposals should be marked "Proposals for Administration Building at Fort Logan H. Roots, Ark.," and addressed to the undersigned or to the quartermaster, Fort Logan H. Roots, Ark. Robert R. Stevens, chief quartermaster.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 14¾@15c.; Lake 14⅞@15⅛c.; casting, 14½@14¾c.

The annual meeting of the stockholders of the Columbus (O.) Edison Company will be held on January 10.

January interest and dividend disbursements in Boston are estimated at $31,254,787, against $24,053,651 in January, 1904.

The Chicago Edison Company is said to be doing the largest business in its history. The order department is nearly a month behind in new contracts.

In a single day the East Boston tunnel proves its value as a time saver; 32,000 passengers paid fares, the business of the ferries being cut about one-half.

The St. Louis United Railways Company reports for the year ended December 31 (partly estimated) a surplus after charges of $2,332,275, an increase of $634,370.

According to documents placed in Comptroller Grout's possession he says the lighting companies of New York owe the city more than $5,000,000 for the use of conduits.

Electric Company of America (Philadelphia) once sold at $23, the par value being $10 a share. Now its earnings are greater than ever before, but the quotation is only $11.

A Philadelphia dispatch says the net earnings of the Electric Company of America for the fiscal year ended December 31 will not be much over $407,000, or 10 per cent. on the stock.

A New York banking firm has purchased $5,000,000 bonds of the Sandusky & Southern Electric Railway Company, which operates an electric line from Sandusky to Wapakoneta, O.

The Rock Island Battery Company, which proposes to do a general electric business, has been incorporated in New Jersey with a capital stock of $75,000. The incorporators are Louis B. Dailey, B. Stafford Mantz and Joseph M. Mitchell.

John I. Beggs, president of the Milwaukee Railway & Light Company and a director of the North American Company, makes this statement: "The reports that the North American Company intends to buy the street car system of St. Louis is without any foundation."

In the litigation to collect judgments amounting to $1,000,000 against the St. Louis Transit Company, the Circuit Court has decided that the United Railways Company, which absorbed it, is not responsible. The St. Louis Transit Company is now out of existence and has no assets.

The gas commissioners have authorized the Lowell (Mass.) Electric Light Company to issue 500 additional shares of stock at $145 a share to fund the floating debt incurred in making extensions to plant. The last public sale of the company's stock was at $180 a share.

Ladenburg, Thalmann & Co. of New York offer to investors Birmingham Railway, Light & Power Company general mortgage refunding 4½ per cent. gold bonds, due April 1, 1954, at 93½ and interest. As its title indicates, the company serves the city of Birmingham, Ala., with local transit facilities, electric light and power. The total issue of the bonds is $10,000,000, of which $2,208,000 are authorized for immediate issue, $5,022,000 are reserved to retire underlying bonds in the hands of the trustee and $2,770,000 are reserved for future improvements. Since its formation the company has paid 6 per cent. dividends per annum on its preferred stock and dividends on its common stock since January, 1903.

EDITORIAL NOTES.

One Hundred Thousand Volts for Power Lines.

An epoch, which well may be called a triumph, has been reached in the history of electric power transmission. Step by step the rising tide of pressures has risen to stay; and now anticipation has become realization and the lightning in truth has been led through miles of wires on its mission of industrial development.

The students of power transmission problems have been guided by the academic propositions laid down in innumerable text books, and have at times strenuously decried the possibilities which thousands of volts represented to the energetic and enterprising engineer for the moving of large powers from their sources to other distant points.

Many questions are involved in such an undertaking; questions which lie at the very heart of the matter. Efficiency, cost of construction, flexibility of operation, insulation and danger among the most important. It sounds like a simple proposal to transmit 10,000 hp. over 100 miles of line and then to distribute it. Here, again, a dual problem presents itself—the problem of transmission and distribution.

Enormous pressures are now in actual use and the limitations of power transmission are best expressed by the limitations in insulation. There is now a plant at Norris, Montana, consisting of two 1,000 kilowatt low-speed generators. This power plant was designed in 1901 and in connection with a further range of 60 miles reaches to the city of Butte. The lines composing this system of duplicate transmission, including the step-up and step-down transformers, were built for the use of pressures of 40,000, 60,000 and 80,000 volts. To reach 100,000 volts for power transmission purposes is but a step which presents no unusual features calling for special consideration. The extensive use of oil insulation for transformers, of air switches in place of oil switches, and of various other changes in insulating methods, point to the attempt which is at this time being successfully made to overcome the difficulties of safe and efficient insulation. It must not be forgotten, that one of the most promine features of expense is this one of insulators and insulation, and success, in reaching over greater distances with these lightning-like pressures is entirely a matter of making cheap and durable, as well as eminently reliable, insulators.

A large power company in Colorado was forced to build its own oil-insulated transformers because of the lack of a guarantee required by it of the manufacturers who were willing to undertake the construction of 40,000 volt transformers only on these negative terms.

It is an extraordinary case of a power company being forced pacifically into the manufacturing business, because they acted as pioneers.

It is interesting to note that the oil in which the transformers were to be immersed was boiled for 24 hours at a temperature of (125 degs. C.) 257 degs. Fah. and the boiling continued for another 24 hours with the transformers submerged. Determination of this kind will soon make even 100,000 volt pressures seem like ancient history.

* * *

The Durability of Telegraph Poles.

As we stated some time ago in these columns, experiments are being made by the Bureau of Forestry of the Department of Agriculture and several prominent telegraph and telephone companies, with a view to increasing the durability of telegraph and telephone poles.

The length of service of a telegraph or telephone pole is determined in a section of the pole not more than a foot or a foot and a half long. In a standing pole this section extends about six or eight inches above and below the top of the ground. This is the universal point of attack upon the life of the pole, and is called its breaking point. Decay is the arch enemy of these poles. It sets in at the ground line and reaches both up and down the pole, but only so far as the conditions exist which promote the growth of wood-destroying fungi. A few inches below the ground there is lack of the necessary oxygen and heat, while at about the same distance above ground the requisite moisture fails. The exact time at which decay begins its work depends upon the climate, the character of the soil, and similar conditions. In a hot, moist climate it ordinarily sets in with great rapidity. But at best, in a very few years after the pole is set the struggle has commenced.

The strain upon the pole from wind pressure and the weight of its cross-arms and wires is calculated for the ground line. When the diameter of this ground line is constantly decreased, the strength of the pole is proportionately reduced, and it becomes only a question of time when the pole must fall. Chestnut and white cedar have been found, among available woods, most successfully to resist decay, but the life of the former is only from 12 to 15 years and of the latter 10 to 12 years. The co-operative study of the Bureau of Forestry is for the purpose of extending, if possible, this time.

The experiments already made show conclusively that poles can be subjected to a preservative treatment which insures materially lengthened service. This treatment consists in impregnating the wood with antiseptics which prevent the growth of the fungi that cause decay. The treatment of telegraph and telephone poles, when attempted at all in this country, generally has been applied to the whole pole, requiring the use of air-tight cylinders 100 feet long or more. In these the poles are subjected to live steam for some time, when a vacuum is created. Creosote is then run in and pressure applied to force it into the wood. Manifestly this is a laborious process. Yet for telegraph and telephone poles only about one foot of the entire length needs to be made immune from fungus, according to the theory of the Bureau of Forestry officials. If this foot at the fatal ground line can be preserved from decay, the rest of the pole will take care of itself. Experiments will now be made in treating the butts of the poles for a distance of about eight feet, thus carrying the antiseptics just beyond the zone of decay attack. The creosote method will be used and the dead oil of coal tar forced through the butt of the pole.

The telegraph companies have made little use of preservative treatment. They employ millions of poles on their various lines, and it would be a tremendous economy to add even a few years of service to the life of each pole.

Another feature of the co-operative work will be the treatment of cross-arms. The companies have been treating them, but report too much absorption in some cases and not enough in others. The Bureau of Forestry will more carefully grade the different kinds of wood and treat each class separately. In this way it is expected to secure a more equal absorption and more satisfactory results. There are the main points covered by the contracts, though in addition the Bureau of Forestry will furnish information on the supply of pole timber and such general advice as may be suggested by the co-operative work.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

The output of electrical apparatus for 1904 is placed at $175,150,000, an increase of $17,000,000 over 1903.

Interborough officials are highly pleased by the showing made by the subway in this city last week. While some of the surface roads were tied up completely and the elevated lines were run irregularly, the underground lines have run as smoothly as they would in mid-summer.

The next convention of the American Institute of Electrical Engineers is to be held this year in Asheville, N. C.

The New York Board of Rapid Transit Railroad Commissioners will meet in its office 320 Broadway, on Thursday, January 12, at 2:30 P.M., to give a public hearing on the report of William Barclay Parsons, chief engineer, suggesting extensions of rapid transit, etc., in the Boroughs of Manhattan, the Bronx and Brooklyn.

Major Woodbury, street cleaning commissioner of New York, in a special report to the Mayor, says that the city refuse, burned scientifically, as it is in certain English towns, will supply three times as much electric lighting as the city now pays for. As the city's annual bill for electric lighting is more than $1,000,000, it could cut this in two by using refuse to generate electricity, and have a revenue of nearly $2,000,000 by selling to private consumers. Major Woodbury's engineering data are furnished by James C. Baylis, his consulting engineer.

The copper production of the world for 1904 is placed by one authority at 632,166 tons, against 578,876 tons in 1903 and 542,167 tons in 1902.

The Southern Pacific is to make a test of an internal combustion engine burning crude oil, and furnishing power for dynamos that generate electricity with which to operate a motor that turns the wheels. In theory it can be operated at one-half the cost of a steam locomotive, is capable of a speed of from 100 to 120 miles an hour, and carries enough fuel to run from New York to San Francisco without renewing the supply.

The thirteenth annual convention of the Northwestern Electrical Association will be held at the Hotel Pfister, Milwaukee, Wis., commencing on Wednesday morning, January 18. Reports and papers on subjects of special interest to central station and street railway men will be read and discussed. An attractive entertainment programme is being arranged, and a pleasant and profitable time is assured to all who attend the convention.

Judge Hazel, in the Circuit Court of the United States for the Southern District of New York, has decided the test suit brought by the New York Phonograph Company against Thomas A. Edison, the National Phonograph Company and the Edison Phonograph Company for an accounting for all sales of phonographs and phonograph supplies made by Mr. Edison and his companies in the State of New York, since the organization of the National Phonograph Company in 1896. As the business done by Mr. Edison and his companies within the State since 1896 has been of great magnitude, it is quite possible that the amount to be accounted for may run up into the millions.

Signor Marconi on Friday, according to a cable dispatch, presented his compliments to the King of Italy who received him with great cordiality. Signor Marconi assured the King that the new wireless stations in Italy will correspond directly with Turkey, Greece, Hungary and the Italian colony of Eritrea, in Africa.

BULL ELECTRO-MECHANICAL WIRELESS TELEGRAPH SYSTEM.

BY A. FREDERICK COLLINS.

A new European system for the wireless transmission of intelligence was recently tried by the Board of Wireless Telegraphy at the Brooklyn Navy Yard, and the results obtained were highly interesting.

The system in question is the invention of Mr. Anders Bull, of Copenhagen, Denmark, and differs in every respect from those that have been previously invented, inasmuch as the Marconi, Slaby-Arco, Braun and Fessenden systems depend on electrical resonance for their selective qualities, while the Bull system utilizes the ordinary non-syntonized sending and receiving apparatus in combination with electro-mechanism to produce these effects.

There is, it should be borne in mind, a great difference in a "selective" system and one that is "non-interfering;" a selective apparatus implies that a message sent from a given station may be received by any one of a number of receivers to the exclusion of all others, while a non-interfering system is one that is not affected by electric waves radiated from any other one, or a number of other transmitters.

Practically there is such a thing as a selective wireless telegraph system, but there is no such thing, except in theory, as a non-interfering system of wireless transmission. While in the present state of the art it is impossible to prevent interference, it is often a great convenience to send a message to a certain given station to the exclusion of all others, and this the Bull system does.

The broad general principles incorporated by Bull in his electro-mechanical methods require a little description before the details are entered into. First of all, the transmitter and receiver are neither tuned individually, nor syntonized collectively. Any kind of a wireless telegraph system may be employed for the purpose of generating and indicating the waves. The Bull apparatus is an auxiliary, feature that when added to any kind of a transmitter and a receiver, becomes an inherent part of it, performing certain well-defined functions, and thereby rendering it selective in its performance.

The apparatus proper consists of a "disperser" and a "collector," as the sending and receiving devices are called, the purpose of the first being to send out a series of pre-arranged wave impulses, and the second to convert these into current impulses. This is done by having two disks, one at either end, rotate in synchronism with each other; each of these disks have contacts that are brought to bear on a number of straight steel springs at predetermined intervals, as will be more clearly indicated later, so that if three series of waves are emitted in a second, these on reaching the receiver will act on the steel springs in the same period of time, and thus close the circuit of the relay, whereas any other series will have no effect whatever.

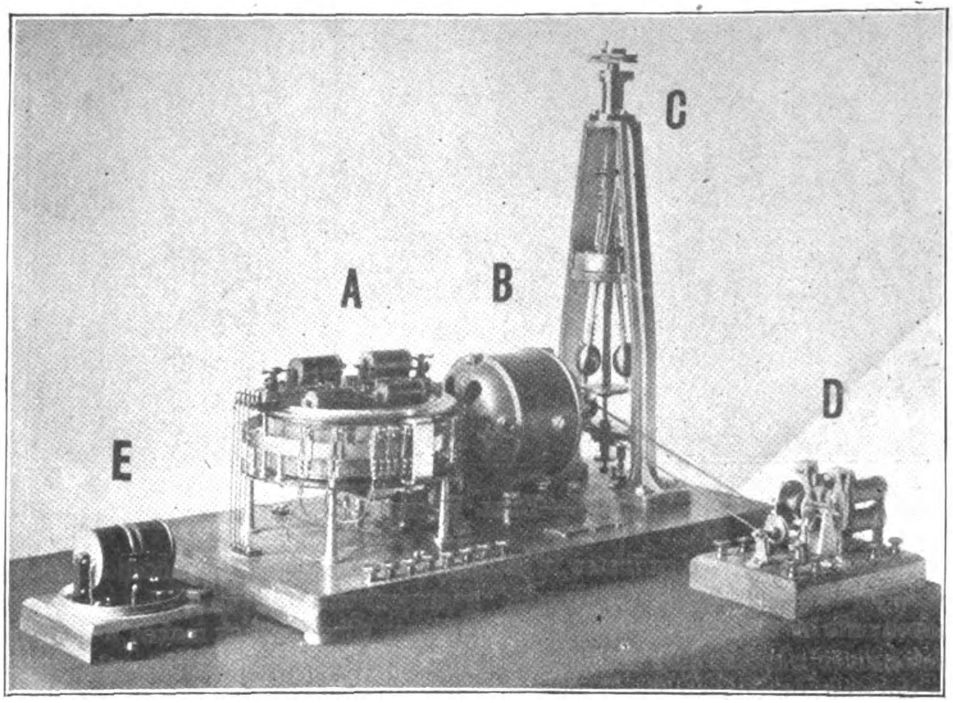

FIG. 1.—THE DISPERSER.

The disperser compresses an electro-mechanical device A, which contains the revolving disk, straight steel springs, electro-magnets and contact points; this is operated by the electric motor B, its speed being subjected to close regulation by means of a Siemens & Halske governor C; an electro-magnet and revolving element for breaking up the primary circuit into a number of impulses during a given period of time is represented at D, while an electro-magnet for making and breaking the circuit of the induction coil of the sending apparatus is shown at E.

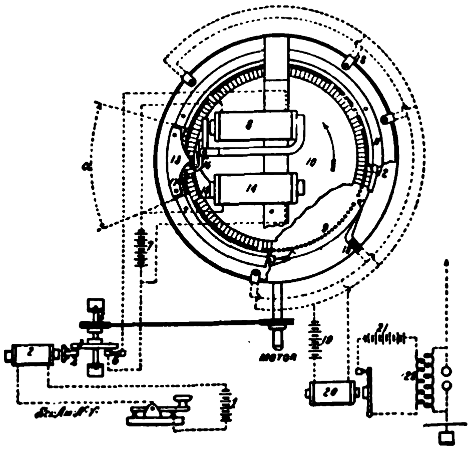

FIG. 2.
The Transmitter, Showing Connections Between Disperser and Induction Coil.

Listed in detail, the entire equipment for sending is made up of an ordinary Morse telegraph key connected in series with a battery 1, and the windings of an electro-magnet 2 (see diagram Fig. 2); the armature of this magnet is attached to a clutch, which may be better understood by reference to the side elevation, Fig. 3; on the surface of the disk 3 a pin engages the clutch 4, attached to the armature, once during every revolution of the disk.

The disk rotates by frictional contact with the shaft 5, thus making approximately five revolutions per second; 6 are spring contact points for closing the circuit including the battery, and the electro-magnet 8. To the disk of the disperser proper, 400 steel springs are attached in such a manner that they stand vertically to the plane of the disk.

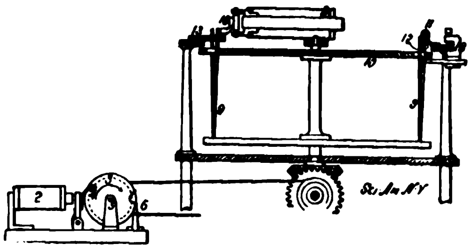

FIG. 3.—SECTIONAL VIEW OF DISPERSER.

In an upper and oppositely disposed disk 10, which, with the first, is mounted on the same shaft or spindle, radial slots are cut, the free ends of the steel springs passing through these, the slots permitting the springs to bend in a radial line only in relation to the disk itself.

The frame supporting the shaft carrying the disks has a brass ring 11, secured to it, the latter acting as a guide for the springs; thus, as they revolve, they may slide within the ring itself, or within the U-shaped groove 12, the bronze arc 13, with its sharp projection extending toward the circularly arranged springs, causes these to bend toward the core of the electro-magnet.

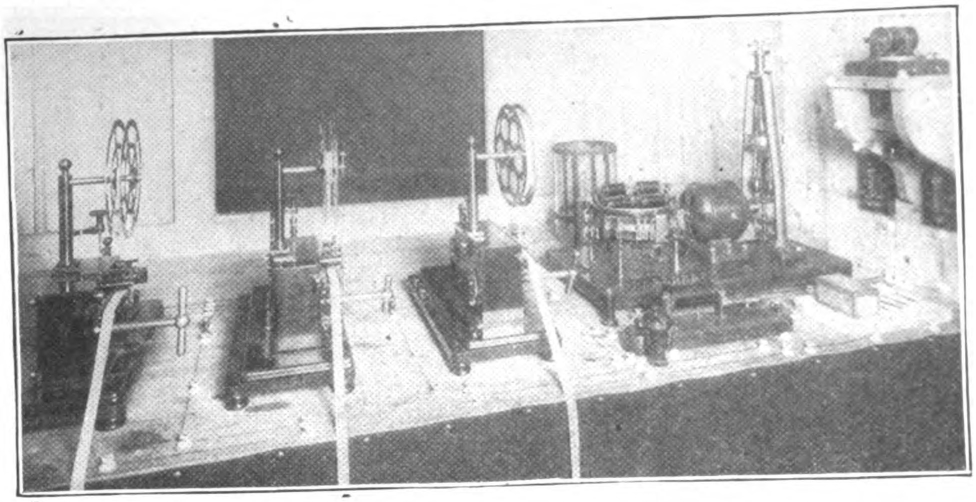

FIG. 4.—BULL RECEIVER.

The end of this core terminates in a curved arm, while a finger 16 directs the movements of the springs; the point that determines whether they are to slide within the ring, or pass into the U-shaped groove, is shown; a number of contact points 18, formed of two contact springs insulated from each other, are attached to the frame.

These are the constituent parts of the disperser, the battery serving to connect the contact points with the magnetic circuit closer 20; a third battery 21, Fig. 2, is connected in series with the primary winding of an induction coil 22, the spark-gap and oscillator system completing the transmitting apparatus.

The collector or receiver device shown in the cut, Fig. 4, and the diagram, Fig. 5, is an exact counterpart of the disperser in so far as the mechanism employed is concerned, but when used as a receiver it is connected with the system which includes the aerial and earth wire and a coherer; these are not indicated by numbers, but with the relay 23, the numerical systematization again begins; the electro-mechanical tapper 24 is of the usual type, the collector magnet 25 being in shunt with it; the groove for the springs is shown at 26. The contact points 27 of the collector are arranged in the same relative positions as they are in the disperser and these are connected in series with the Morse system.

Having defined the various necessary parts of the Bull system it is now in order to review the operations of sending and receiving a selective wireless message. Beginning at the transmitting end the first effort consists of the manipulation of the Morse key. When the first circuit is closed through the key the current from the battery, Fig. 2, energizes the electro-magnet 2; this attracts the armature, permitting the disk 3 to revolve, which it does at the rate of five revolutions per second, by drawing the clutch out of engagement with the pin 4.

Every time the disk makes a complete revolution the pin 3 strikes the spring contacts 6, closing the circuit, which includes the battery 7 and the electro-magnet 8. Now, if the Morse key is depressed only long enough to represent a dot, this being less than one-fifth of a second, then the clutch will engage the pin and the disk will be brought to a full stop when it has made one complete turn. It is evident that the magnet 8 will be energized with a single impulse, but if a dash is sent the disk revolves several times when the successive impulses energizes the magnets at intervals of one-fifth of a second.

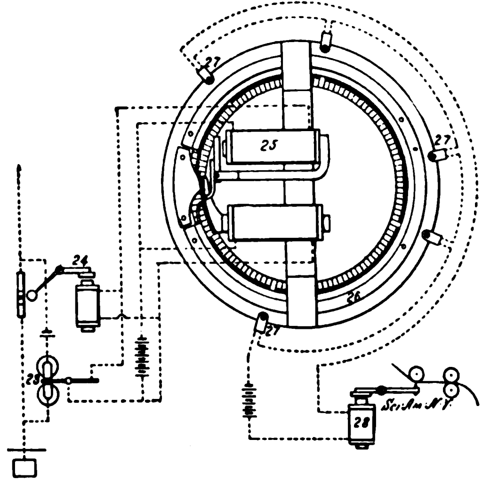

FIG. 5.
The Receiver, Showing Connections Between Coherer Relay, Morse Register and Collector.

In this case the steel springs 9 on the larger disk, which makes one revolution every second, are guided over the polar projector 15 of the magnet 14 in shunt with the battery 7, the finger 16 is fastened to the armature of the magnet 8 and when this is attracted the springs are turned out of their normal course into the U-shaped groove 12, remaining there until the disk has completed its cycle.

When the springs move in the U-shaped groove they make connection with the contact points 18, since they project a little beyond the normal circumference of the points themselves. It is easy to see that by closing the circuit formed by the battery 21 the induction coil 22 will also be closed and that trains of waves will be set up that are periodic both in time and space.

As the disk of the collector revolves at exactly the same speed as that of the disperser, no matter how great the distance separating these may be, the electric waves sent out by the transmitting aerial will, on reaching the receiving aerial wire, be converted into electric oscillations representing similar periodic impulses and these break down the high internal resistance of the coherer when the local current operates the relay 23; this brings into action a battery that energizes the magnets of the decoherer 24 and those of the collector magnets 25.

It must be apparent now that for each series of wave impulses one of the straight steel springs will be brought into the groove 26; thus if five electric waves series are transmitted, five springs will be brought into the groove of the collector at space intervals representing the intervals of time between the series of waves.

As the contact points in the collector are arranged exactly as they are in the disperser, all of them must be brought into contact simultaneously; hence the circuit which includes the Morse register is closed and the dot and dash is imprinted on the tape. A disperser having any other combination than the collector would not, of course, cause every contact of the latter to be closed at the same instant and this would permit the Morse register circuit to remain open.

In the trials made in Copenhagen by the inventor only one transmitter and one receiver were employed each of these having three sets of contact points and any one of these three combinations could be used to the exclusion of the other two by merely cutting them out by means of a switch. The collector had three Morse registers connected to the various sets of contact points and by making the points of both instruments correspond any one of the three registers could be operated selectively.

In the tests just concluded at the Brooklyn Navy Yard the apparatus operated admirably and proved beyond the peradventure of a doubt that wireless telegraph messages may be sent selectively by the adoption of the Bull system. It is the first time on record that selective messages have ever been actually accomplished in America.

TELEPHONE PROTECTIVE DEVICES.

BY RALPH SCOTT.

(*Concluded from page 5.*)

On account of the great increase of the application of high tension circuits and their coincident installation with telephone circuits, it is necessary that the latter be protected against crosses with the former. Among such high tension circuits may be mentioned street railway, power and lighting systems, especially where alternating current is used.

Although a dynamic current of even a very high voltage is not capable of jumping across even a very minute air space, when an arc has once started by a static discharge passing across this gap, a dynamic current in the form of an arc will continue across this path even though it be of comparatively great length.

This arc, by fusing the circuit wires, may cause a permanent connection at this point which may thus result in the telephone circuits carrying a high tension current. It is necessary, therefore, that a good protector open the circuit before entering the building. Hence, it is essential that combination protectors be used which will provide a good path to the earth for not only the high tension current but also the static discharge. It is also necessary that a fuse be so located that when a cross occurs with a high tension circuit it will not only handle this discharge but also be so sensitive that in the case of sneak currents, or partial crosses, it will interrupt the circuit and thus protect the instrument.

In Fig. 9, a device which depends in action upon the electromagnetic effect of a current, is shown. One side of the instrument to be connected is connected to the end N of the electromagnet R. The other end of the magnet is connected to the frame D. The pivoted armature O, held upward by the adjustable spring C is provided with a catch A, which holds the pivoted lever L in the position shown; L tends to move away from the restraining catch A, because of the spring S. When an excessive current passes through R, from N to E, the armature O is attracted, thus allowing L to fly outward, and introduce a wide air-gap, which disrupts any consequent arc.

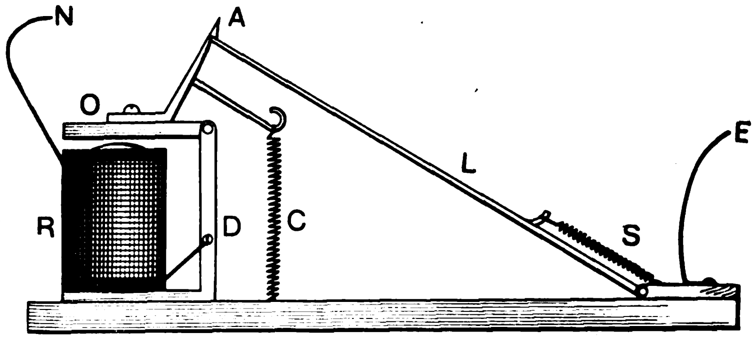

FIG. 9.

In Fig. 10 is shown the simplest form of protector against excessive currents. Upon a suitable base the binding posts N and A are placed, to which are connected the line and instrument wire respectively, and between which is placed the fusible wire D. On the passage of an abnormal current, the thermal effect is sufficient to melt D, thus introducing a wide air gap between A and N.

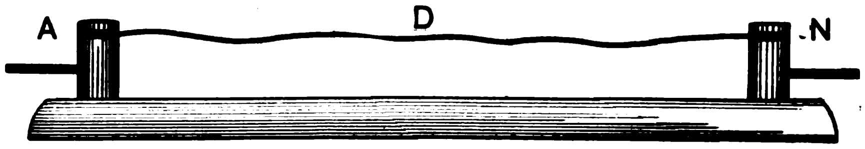

FIG. 10.

Modern telephone protective devices may be classified into the following subdivisions: (a) Protectors for switchboards at the exchange; (b) protectors for cables, which usually are placed upon line poles; (c) protectors for the instruments at the subscriber's end of the line.

It is now recognized that a perfect system of protection must include both line wire and instrument fuses, a self-heating coil, a carbon plate lightning arrester (single pole for grounded circuits and double pole for metallic circuits) and also a grounding device by means of which any separate line may be connected to ground.

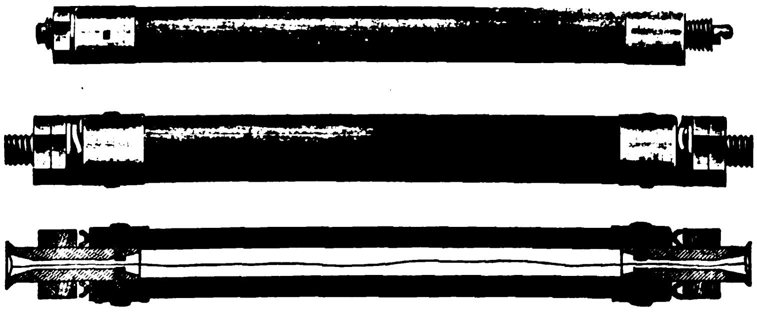

FIG. 11.

Although a great number of devices for accomplishing the above purposes have been placed upon the market within the last few years, nearly all are similar in principle, and a description of one standard form may serve as a description for nearly all other devices which perform the same function.

The old style protectors usually employed a self-heating coil which opened the circuit by the melting of either a soldered or waxed connection, which, when the device had operated, required renewing. As a matter of fact, a protector which is designed after these principles is usually not only complex but also clumsy, as the principle of operation is not ideal.

For this reason there are a number of so-called self-soldering devices on the market, which, by the use of a suitable arrangement of contacts and parts, are reset for another operation of the protective part after having been disrupted by an excess of current. Present practice demands that a telephone protector should fulfill the following conditions:

1. It should be provided with a self-soldering or self-restoring heat cartridge or other readily renewable arrangement, which will require but little time to replace after the same has operated by the flow of an excessive current.

2. The protective coil or cartridge should be in such a position and having such connection that it may be readily tested and operated any number of times without any change in the relative efficiency of the device.

3. The heat coil should have a definite and invariable rating, so that it will not

pass a greater current than that at which it is rated for any length of time.

4. The springs or other means employed for operating the device on the passage of an excessive current should be of such construction that their long continuous use in their strained position will not effect their resiliency. The tension of the springs should be such that a good contact is maintained, and also that when open it will introduce a liberal air-gap.

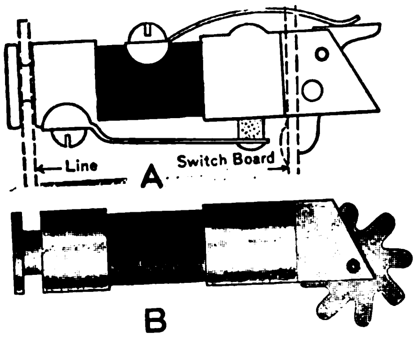

Fig. 12.

5. The air-gap between the contacts should be distinct in such a manner that, when the parts are in open condition, there will be no liability of any contact or short-circuiting action between any of the other parts of the instrument.

6. The grounding device should be of such construction that a permanent ground will be assured when operated.

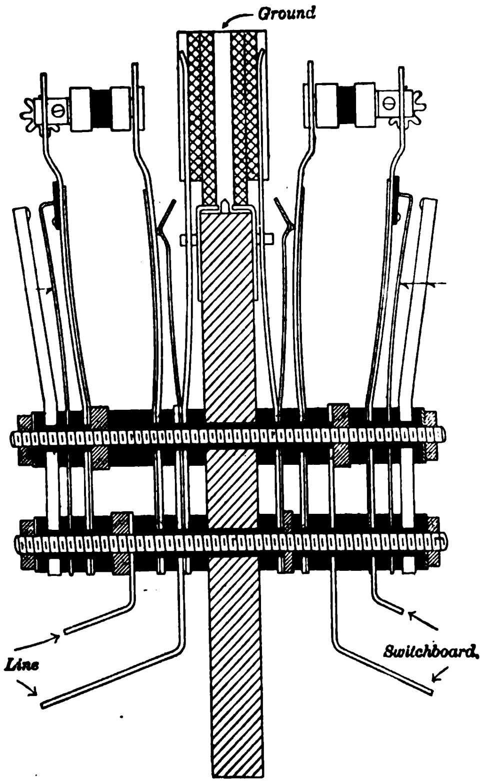

Fig. 13.

7. All contacts should be in a readily accessible position, so that in case of uncertainty of action the parts may be readily inspected. On switchboard protectors it is necessary that the usual testing arrangement be readily applied.

8. The lightning arrester employed should be positive in action and also self-cleaning. Its construction should also be such that an altering of the position of the parts after leaving the factory will be a remote possibility.

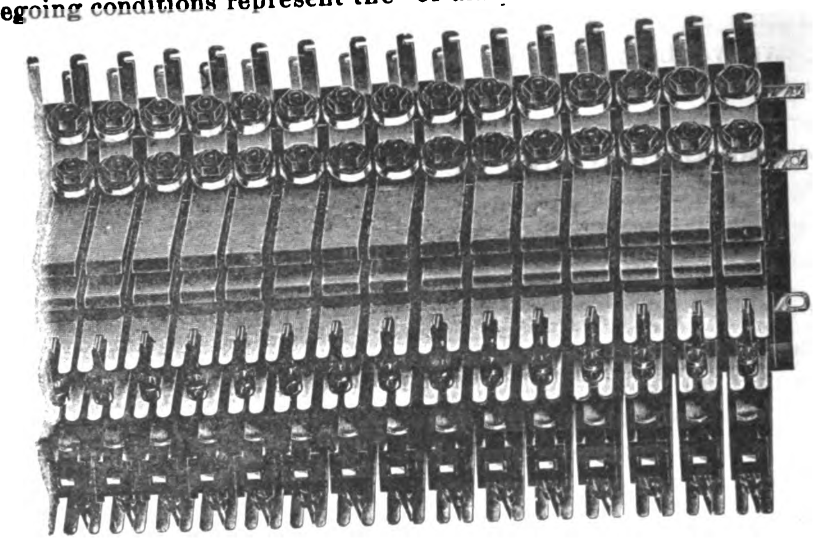

Fig. 14.

The foregoing conditions represent the practical requirements after which all protectors should be designed. The primary object of a protector is protection. This, therefore, should be the objective point of all such designs,

Tubular line fuses, which have been largely applied to the protection of open telephone lines, are usually placed at the outside of the building and fastened to a break in the line itself. Such line fuses are shown in Fig. 11, and consist essentially of fiber tubes with suitable end connecting and clamping means. Through the center of this tube is passed a fine fusible wire, which, when disrupted by an excessive current, is converted into a gas, the high resultant pressure effectually quenching any coincident arc.

In Fig. 12 is shown two forms of self-soldering heat cartridge. The type shown at A consists of a graphite rod of high specific resistance, to which suitable end connecting means are fastened. One of these end terminal pieces contains solder, which normally holds the pivoted contact piece in place, thus holding the contact spring in its tension position. When an abnormal current passes through the graphite rod, the heat generated melts the solder and releases the pivoted piece. After release the top spring forces the pivoted piece in its original position, thus resetting the device. At B is shown a star wheel cartridge, which consists of a heat coil housing fastened to a wheel by solder. In operation the wheel turns, thus releasing the spring and resetting the wheel.

In Fig. 13 is shown a section of a standard form of telephone switchboard protector. This shows the method of operation, and also the construction of the component parts. The heavy outside strips on each side and the adjacent spring pieces which are insulated from the cartridge springs constitute the local or alarm circuit.

On each side of the centrally located ground plate the carbon lightning arresters are placed. The heat cartridges are shown in their normal condition, that is, before having operated. The central or ground carbon block is square, being provided with a square aperture, which slips over a grounded rod. The line and

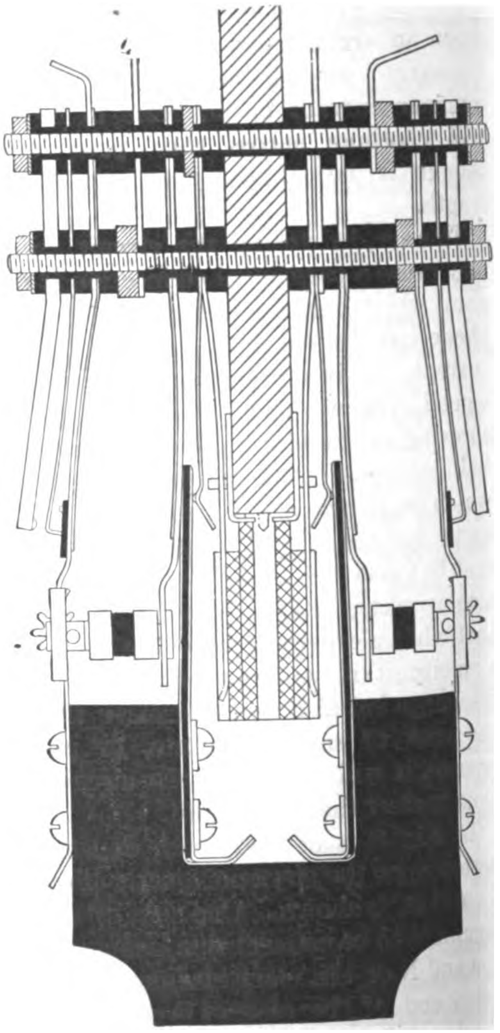

Fig. 15.

switchboard lugs are beneath the row of protectors.

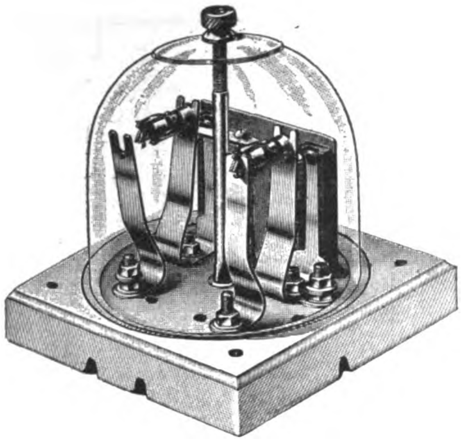

Fig. 16.

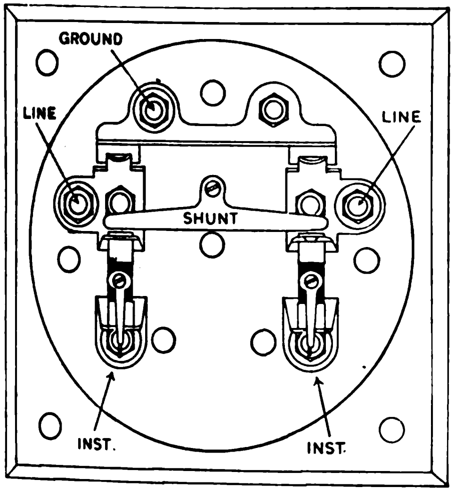

Fig. 17.

The protector, in operation, causes the local or alarm circuit to be closed, opens the line circuit, and shunts the excessive current to ground, these operations being accomplished very quickly. The heavy current, in passing through the cartridge, softens the solder and allows the wheel to revolve, which releases the springs holding the cartridge in place, thus causing the outer spring to close the local circuit, and the inner spring to ground, the line circuit being at the same time opened and an air-gap of one-half inch being introduced. A bank of these protectors is shown in perspective in Fig. 14.

In Fig. 15, the manner of testing a switchboard protector by means of a standard test plug is shown. By means of this arrangement it is possible to make any of the usual telephone tests without distributing even the individual protector. There are three distinct sets of contacts, by means of which any of these tests, either in series or multiple, may be made.

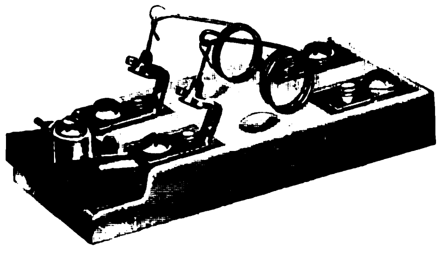

Fig. 18.

In Fig. 16 is shown a self-soldering heat coil and arrester protector. A diagram of the connections and arrangement of the parts of this instrument is shown in Fig. 17, which is self-explanatory. The operation of either heat coil causes the spring on the latter to come in contact with the pivoted shunt bar, which successfully shunts the instrument. On replacing the release spring, the shunt is removed. Two forms of heat coil protectors with spring release are shown in Figs. 18 and 19. The arrangement in Fig. 18 consists of movable heat coils only, the springs and contact pieces being rigidly secured to the porcelain base. The instrument shown in Fig. 19 has removable heat coils and springs, these being placed on fiber bars provided with contact clips, which may thus be removed expeditiously.

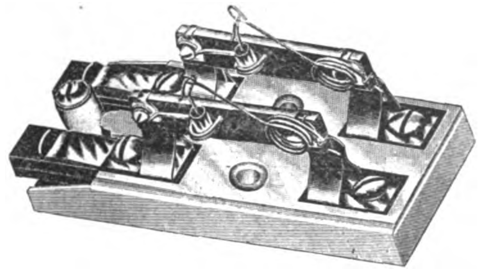

Fig. 19.

ELECTRICITY LEAFLETS.

BY NEWTON HARRISON, E. E.

ELECTRO-MAGNETISM.

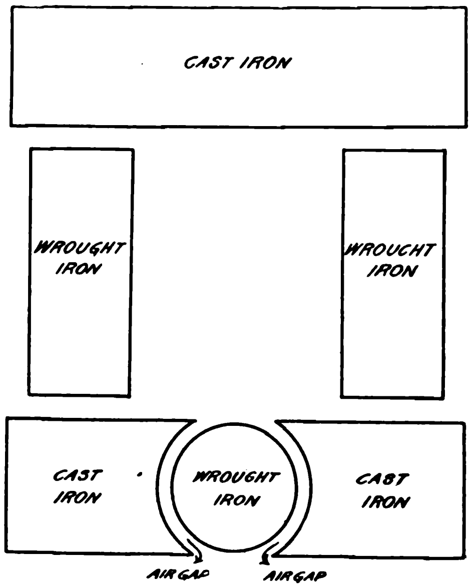
Winding Magnets.—The winding of magnets is accomplished by considering first the number of lines of force per unit of area of cross-section and, secondly, the number of ampere turns required to produce a uniform magnetic condition throughout the iron, steel or air under process of magnetization. The number of lines of force per square inch of cross-section is the basis of most estimates made in this direction. But the other important fact to consider is the number of inches which represents the total length of the magnetic circuit.

The Hopkinson Method.—The estimates of the amount of magnetism produced from a magnetic circuit only became accurate through the application of the method of John Hopkinson, an English scientist and engineer.

This method consists of the division of the magnetic circuit into its separate parts, such as the cast-iron, the wrought-iron and the air-gap. Each part carries a certain number of lines of force per square inch and has a certain length. In other words, it is necessary to provide a certain magneto-motive force for each distinct part of the magnetic circuit. All of these magneto-motive forces are added together in the shape of a sum total of ampere turns constituting the field winding. Thus two processes come into view: First, that of obtaining the total magneto-motive force and, second, that of obtaining the correct winding, size of wire, etc.

Taking a practical view of the Hopkinson method it is evident that it calls for the use of curves already made with reference to the metal, whether wrought or cast-iron, under consideration.

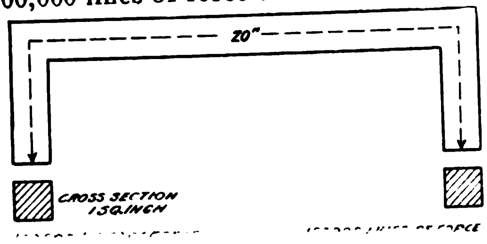
To illustrate the idea involved in its application take the case of a dynamo which, as seen in the illustration, represents a magnetic circuit composed of many parts—the keeper of cast-iron, the magnet cores of wrought-iron, the pole pieces of cast-iron, the armature core of wrought-iron and finally the air-gap lying between the armature core and the pole pieces. The problem from an everyday practical standpoint is that of finding the total number of ampere turns required to force a given number of lines of force through the armature core from pole piece to pole piece. In order to do this, as stated before, each individual part of the magnetic circuit must be provided with sufficien magneto-motive force to develop in it the amount of magnetism or number of lines of force required to establish this result.



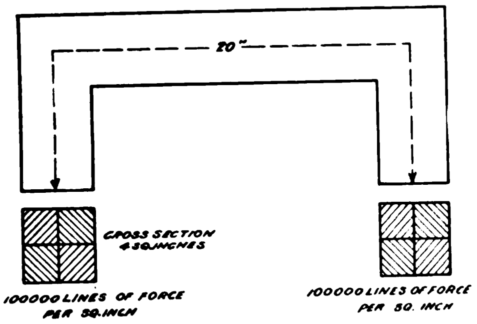
Parts of a Dynamo.

Suppose, for purposes of illustration, in order to send 100,000 lines of force per square inch through wrought-iron it takes 92 ampere turns per inch length.

Then, if the bar is 20 inches long and of 1 square inch cross-section and carries 100,000 lines of force the number of ampere turns required would be equal to 20 × 92 = 1,840 to produce the induction, as it is called, per square inch. If a magnetic circuit of the same material, the same length, but four times the cross-section is considered, then the fact to be remembered is this—that here the length of the magnetic circuit has not changed and therefore the magneto-motive force will not be any greater than in the first case; but the cross-section of the iron being four times as great means a magnetic reluctance of one-quarter and therefore four times as many lines of force in consequence.



Total Field 100,000 Lines of Force.



20"
CROSS SECTION 4 SQ.INCHES
100000 LINES OF FORCE PER SQ.INCH
100000 LINES OF FORCE PER SQ. INCH

Total Field = 400,000 Lines of Force.

The same number of ampere turns would be required for either bar of wrought-iron because the length and quality of the iron of each is the same. Now it does not make much difference whether these ampere turns are placed along the whole length of the bar or at one portion of it. The total number required in this particular case is 1,840 to produce 100,000 lines of force per square inch throughout the bar. The bar might have a cross-section of 100 square inches, if it has the same length the same number of ampere turns will be required to give every square inch of its cross-section an induction of 100,000 lines per square inch. The important part is to provide the required number of ampere turns per inch length. These figures, for different grades of iron or steel can be obtained from curves or tables. A very important table of this character, prepared by Alfred E. Wiener, E.E., is here given for the uses indicated, namely, the calculation of the ampere turns of any magnetic circuit of any material in ordinary use.

UNIT MAGNETO-MOTIVE FORCES.
Ampere Turns per Inch Length.

125,000.	900.	950.				

Referring to the first sketch it is now easy to see that the Hopkinson method would call for this process with reference to the table obtained from magnetic curves.

1—Lines of force per square inch in cast-iron keeper and the corresponding ampere turns per inch length.

2—Lines of force per square inch in wrought-iron cores and the corresponding ampere turns per inch length.

3—Lines of force per square inch in cast-iron pole pieces and the corresponding ampere turns per inch of mean length.

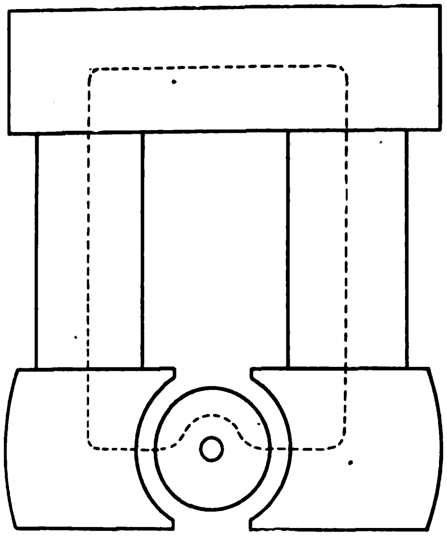
4—Lines of force per square inch in wrought-iron armature and the corresponding ampere turns per inch of length.

5—Lines of force per square inch of air gap and the corresponding ampere turns per inch or percentage of an inch of length.

The selection of the mean path through the parts of a dynamo is shown by the dotted lines in the sketch. After getting the total ampere turns for each part of the dynamo the following schedule is arranged:

Ampere turns for magnet cores....	1,000
" " " keeper..	200
" " " pole pieces......	300
" " " armature core...	100
" " " air gaps........	2,400
Total ampere turns...........	4,000

With the total ampere turns, the next step is to find the proper size of wire as called for by the electromotive force of the armature which supplies the field winding, Formula for Winding.—The simple formula employed for the winding calls for a knowledge of the total ampere turns, the volts to be applied to the terminals of the coils, and the average or mean length of one turn. This last is obtained by taking the diameter of the magnet core and adding to it the anticipated depth of winding in inches. Between these two an average is obtained and multiplying by π gives the length in inches, called the mean length of a turn. The size of wire is given in circular mils.



SHOWING MEAN PATH OF MAGNETIC LINES OF FORCE THROUGH THE FRAME OF A DYNAMO.

Circular mils =

$$\frac{\text{Total amp. turns} \times \text{mean length of turn}}{1.106 \times \text{volts of coil}}$$

$$\text{C. M.} = \frac{\text{A. T.} \times \text{M. L.}}{1.106 \times \text{E}}$$

Suppose in the case of a dynamo whose total ampere turns equal 4,000, the mean length of a turn equals 12 inches, the size of wire required equals the following at 110 volts:

$$\frac{4{,}000 \times 12}{1.106 \times 110} = 312 = \text{No. 25 B. \& S.}$$

gauge nearest size.

Allowing 1,000 circular mils per ampere gives a current of .325 of an ampere. Dividing amperes into ampere turns gives turns = 12,307; as each turn is about 1 foot there are approximately 12,000 feet of wire.

The temperature of the coil must also be considered, because the greater the amount of power dissipated in the coil in the form of heat the higher its temperature becomes. This will destroy the coil unless regulated by the outer surface of the coil itself and the depth of winding. A simple formula gives the temperature in degrees Fahrenheit to which a coil will rise when two things are known, the watts wasted in the coil and the number of square inches of radiating surface to the coil.

Obtaining the Watts Wasted.—To obtain the watts wasted in heat in the coil, the resistance of the wire in ohms must be multiplied by the square of the current. For instance, in the coil referred to in illustrating the winding formula there are 12,000 feet of No. 25 wire This wire has a resistance of about 32 ohms per 1,000 feet or a total of 32 × 12 = 384 ohms. The current this coil carries is equal to its circular mils divided by 1,000, or

$$\text{Current in coil} = \frac{\text{circular mils}}{1{,}000} = .325.$$

The number of watts wasted are equal to ohms × the amperes squared = .325 × .325 × 384 = 41 watts.

Temperature Formula.—The formula for calculating the temperature is as follows:

$$\text{Degrees Fah.} = \frac{100 \times \text{watts wasted}}{\text{sq. in. of radiating surface}}$$

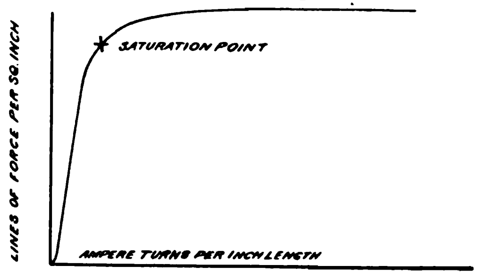
The watts wasted in this case are equal to 41, and if the square inches of radiating surface equal 100, the total rise of temperature in degrees Fahrenheit would be

$$\text{Degrees Fah.} = \frac{100 \times 41}{100} = 41 \text{ degs.}$$

This is not an excessive temperature and can be allowed.

The point to grasp is the influence of an increase or decrease in the radiating surface upon the temperature of the coils. The amount of heat generated in a coil due to the resistance and current is about constant under ordinary circumstances. If the means by which this heat can escape are limited the temperature rises. On the other hand, if the radiating surface of the coil is large the heat readily escapes and the temperature is lower. The problem is largely one in physics, where the heat is limited in quantity but the surface through which the heat escapes can be made larger or smaller, in which case the temperature drops or rises. If, for instance, the heat of a candle flame is concentrated at a point, that point would rise to the temperature of blinding incandescence. On the other hand, the heat, if imparted in its entirety to a large body of necessarily large radiating surface, would escape at a low temperature. The temperature of the body, therefore, is as much a question of the radiating surface, its character and extent, as the amount of heat it represents. In the case of a coil the temperature should not rise much above blood heat or 100 degs. Fah. If the coil develops a temperature of its own of 41 degs. and the surrounding air is at 60 degs. then the total temperature would be 60 + 41 degs. or 101 degs. If a coil of this kind is used in a place unduly heated, or, if it be put into operation near the tropic belt, then the temperature of the coil would become excessive. The surrounding atmosphere must be considered in the design of magnet coils, particularly when they constitute parts of dynamos in use in engine rooms whose temperature is generally very high. The resistance of a winding is increased by its own heat, and this to some extent cuts down the flow of current, which is otherwise very sensitive to changes of resistance, particularly when the resistance falls.

The Magnetization Curve.—The curve which shows the internal condition of the iron is called the magnetization curve. It is obtained by plotting a curve whose elements consist of ampere turns per inch length and the number of lines of force they produce at each successive stage of magnetization. The value of such a curve in practical work is easily seen when the rise and direction of the curve is noted. The rapid rise of the curve with a very small magnetizing force shows how sensitive the iron is to magnetic influences when its reluctance is low and its permeability high. The result is a curve which rises with a slight inclination and then begins to bend. The bend of the curve indicates a distinct change in the permeability and consequently the reluctance of the iron. Following the curve for a short distance it is seen to bend with more and more tendency to the horizontal plane, reaching which it begins to move along it. At the critical point, where the bend originally begins, it will be noted that a given magnetizing force in ampere turns does not produce the effect it did before. In fact a little beyond this point it takes a comparatively great magnetizing force to produce a little additional magnetic field.



SATURATION OR MAGNETIZATION CURVE.

This point is called the saturation point and is considered in practice the economical point at which to operate the iron. Beyond this point magnetism is obtained at too great an expense in wire and power. It is about 100,000 lines of force per square inch for wrought-iron and about 80,000 lines of force per square inch for mild steel, of which two metals the majority of dynamo frames of the present era of electric lighting and power transmission are made.

In the curve the base line represents the ampere turns per inch length, the vertical lines, the magnetic lines per square inch of cross-section.

ON BATTERIES WITH REVERSIBLE BOOSTERS[*]

BY C. TURNBULL.

Some time ago I found it necessary to go into the question of having a battery and automatic reversible booster for use on the traction load at Tynemouth. The result of the investigation was the birth of the Lancashire Automatic Reversible Booster, which was brought out under the patents of Mr. McLeod and myself. This is now in considerable use, being made by the Lancashire Dynamo & Motor Company of Manchester. In putting the machine into the various stations a number of points have come up in connection with the batteries, and I wish to deal with them, in hopes that the paper may be of use to such engineers as are putting down batteries for use under similar conditions.

Price for Traction Current.—The method by which the price for traction current is fixed is one of mystery. Sometimes I think that the lowness of the rate obtained for this kind of supply is partly to be accounted for by the fact that we sell in small units. Certainly the reduction from 2d. to 1d. per unit looks a good deal less than the reduction of a year's revenue from, say, £4,000 to £2,000. At any rate, however the price is fixed, it commonly happens that, when a station engineer takes over the management of a station, he finds the glorious tramway load, from which so much is expected, resolves itself into a small output at a remarkably small price, and the problem of making it pay occupies his thoughts for many years to come. I make these remarks here, as in addition to the Greenock case, other instances are coming to light in which the trams are claiming to be supplied at the same rates, or lower, as are in force for ordinary motor load, although it is common knowledge that tram load is of an entirely different description from motor load, and should be dealt with on its own basis. The practice of debiting all stand-by plant which can be used for both lighting and traction, to lighting only, is also not to be commended.

Load Factor.—The large published load factors for traction supply in combined lighting and traction stations are frequently made use of when a low rate for traction is asked. Certainly a 40 per cent. load factor (for I think a figure as high as this has been given) looks a lot better than the 10 per cent. for lighting. Actually, these large load factors are explained by the fact that the traction load is taken as that load which is on at the moment when the highest total combined load is on the station. Seeing that the highest combined load is usually on the station in the winter months, at a time when the traction load is often lower than its normal maximum, this system frequently causes the traction to be credited with a load factor much greater than it actually earns. To take an extreme case—in a station just beginning the highest combined load might be in the summer holidays, when the trams were heavy and the lighting very low. This would give a low traction load factor and a lighting load factor of perhaps 1,000 per cent. In a few year's time, when the station had grown, the lighting load factor might have shrunk to ordinary dimensions, while the traction load factor might come out very high. I think there is a good deal to be said for taking the respective highest loads for calculating the respective load factors. In connection with this we must also remember that while an engine may be run at nearly full load all the time on motor load, on traction load one must always provide a very large reserve of power to meet the grossly fluctuating demands which traction involves, and this does not make for economy in generating the power.

Batteries.—It has now come to be recognized that the best way to deal with a very fluctuating traction load is to put in a battery and reversible booster, and I propose to deal with some of the aspects of this solution of the problem. The idea has gained currency that a booster should be designed to keep the load on the generator always at a steady value. The problem is stated thus, omitting losses in battery and booster for simplicity—the output is 2,000 units per day of 20 hours. Then a 100 kw. generator with a battery and booster will just do the trick. If the maximum load be 200 kw., then the battery should be able to give 100 kw. easily for a short time, so as to meet the peak with the aid of the generator.

In some cases where the output is fairly regular from day to day, and where the maximum demand keeps within limits, this solution of the problem is quite good, and a very efficient and good working plant is obtained by adding a battery and booster to the generator. In many cases, however, this solution is of no use at all. The output varies from day to day. Likewise a large part of the day is slack, with a heavy output during certain hours only. If in addition to this we have heavy and irregular peaks at all times, then it is evident we must solve the problem in quite a different manner. Take, for instance, a case where there is already installed a plant of 200 kw.; the output varies from 1,500 to 2,500 units per day of 20 hours, and the maximum demand is 400 kw. Then, if we put a battery in with an output of 200 kw. for a short time, its maximum power added to the generator's maximum will give the required maximum demanded for the feeders. But if we attempt to run the generator at constant full load all the time, it will give off 4,000 units per day, and this will provide a large surplus at all times for boiling up the battery. The difficulty can be met by putting the machine to do only half load, but in this case the combination does not give out the 400 kw. needed to meet the heavy peaks which come on at intervals. Taking everything into consideration, then, it will be found that constant load on the generators can only be got in cases where the load is similar every day, and keeps on fairly regularly throughout the day, and where the size of the generator can be fixed so as to put out the proper amount of current every day at about full load. Of course, in many cases, a good deal can be done by varying the number of hours that the generator is run, so as to provide just the number of units required to meet the load and to keep the battery properly charged.

Properties of Booster.—For a general solution of the problem the booster should have very flexible properties. It should, indeed, fulfill the following requirements:

1. When required, it should work so as to keep the load on the generator approximately steady. This will be needed when the demand for current is approximately equal to the output of the generator. In this case, however, when a very heavy demand is made on the feeders, both generator and battery current should rise to meet it, so that the utmost power of the combination will be available. If this be not arranged, it will often be found that a heavy load will blow first one circuit and then the other, although

---

[*] Paper read at the meeting of the Newcastle Section of the British Institution of Electrical Engineers, December 12, 1904.

the combined maximum power of the battery and generator would have sufficient to meet the demand had the booster been arranged to allow the generator output to increase along with the battery's output.

2. It should be possible to vary the apportionment of the load between the battery and generator. In a slack time the battery should do very little. Also, if the traction peak should correspond with the lighting peak, then it may be desirable to let the battery take an extra load to relieve the boilers for the time being.

3. On a slack day with occasional peaks the battery and booster combination should be arranged to respond to the peaks only, and otherwise do practically nothing, so as not to overcharge the battery. Sometimes the booster may be cut out altogether, and the battery may then with advantage be used to float on the line to meet any occasional rush of current.

4. For periods of very light load, the booster and battery should be arranged to go on to the bus bars without any generator. In this case the booster should be arranged to compound up to counteract the drop of volts in the battery.

I might point out that a booster worked by the feeder currents only will not fulfill these requirements, as such a combination will tend to take the load off the generator when the battery is fully charged, while it will be sluggish and unresponsive when the battery is down at all in volts.

(To be continued.)

The Institute's Annual Dinner.

The annual dinner of the American Institute of Electrical Engineers will be given in the ballroom of the Waldorf Astoria, New York City, on February 8, and promises to be a most interesting occasion. In view of the recent opening of the Subway, thus adding underground traction in America to the domain of electricity; the adoption of electric locomotives for their great Manhattan terminal divisions by the New York Central and Pennsylvania Railroads, the equipment of the Long Island Railroad with electricity, and other signal events, the Institute has decided to devote this dinner to emphasizing the triumph of electric traction. A number of pioneers and leaders will be present. An original menu has been designed, and some novel features will be introduced, while the list of speakers includes men of national and international reputation. The dinner will be served for $5 per cover without wine or cigars, and as is usual on these occasions ladies will be present. The participation of the ladies was a feature that elicited Mr. Carnegie'e enthusiastic commendation at the famous Institute Library dinner, which he made forever memorable by his million dollar gift for the United Engineering Building. Notices will be sent to the members forthwith, and it is requested that an early response be made, in order that proper care can be taken of all applications. Over 400 had to be seated at the Edison dinner last year, and the attendance in February promises to be equally large.

◆

Proposals Invited.

The Bureau of Supplies and Accounts of the Navy Department is inviting sealed proposals until January 24, for furnishing the navy yards at Boston, Portsmouth, New York, League Island, Norfolk, Washington, and elsewhere, with the following: Schedule 33, arc lamps and electrical supplies; schedule 34, incandescent lamps, wire and cable, conduit and fittings, buzzers, Weston ammeters, armatures, circuit breakers, telegraphs and indicators, bracket fans, LeClanche battery cells, thermostats, carbons, fuses, and miscellaneous electrical supplies; schedule 36, electrical supplies; schedule 37, motors. Proposal blanks will be furnished upon application to the navy pay offices in the above-mentioned cities or to the Bureau. Applications should designate the schedules desired by number.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED JAN. 3, 1905.

Electric Railways and Appliances.

778,933. Trolley Catcher and Retriever. Charles F. Wilson, New York City. Filed Aug. 19, 1903.

778,958. Electrical Door-Releasing Device. Frank M. Edmons, Holyoke, Mass., assignor to the Coburn Trolley Track Manufacturing Company, Holyoke, Mass. Filed March 27, 1903.

778,987. Trolley. William W. Mercer, Norfolk, Va., assignor of one half to Benjamin J. Cady, Washington, D. C. Filed May 28, 1904.

779,075. Block System. Antonio Fiorini, Pontremoli, Italy. Filed April 13, 1904.

779,150. Third-Rail System. Giosue D'Esposito, Pittsburg, Pa., assignor of one-half to Stuart Patterson, same place. Filed March 12, 1904.

779,204. Electric-Railway System. George L. Campbell, Nyack, N. Y., assignor to the American Construction Company. Filed Oct. 11, 1902. Renewed July 8, 1904.

779,390. Signaling for Railways. William S. Berry, Pittsburg, Pa. Filed May 25, 1903.

779,401. Trolley-Pole Controller. Arthur W. Harrison, and Eugene H. Fosdick, Los Angeles, Cal. Filed June 2, 1904.

Electric Lights and Appliances.

778,913. Rheostat for Electric-Arc Lamps. Bernard A. Stowe, Cleveland, O., assignor to the Jandus Electric Company. Filed Oct. 28, 1903.

778,914-915. Electric-Arc Lamp. Bernard A. Stowe, Cleveland, O., assignor to the Jandus Electric Company Filed April 30 and May 19, 1904.

778,984. Electric-Lamp Bracket. Edwin H. Lux, Logansport, Ind. Filed June 10, 1904.

Electrical Machinery and Apparatus.

778,834. Means for Ventilating Electrical Machines. Albert Aichele, Baden, Switzerland, assignor to the firm of Actiengesellschaft Brown, Boveri & Co., same place. Filed Dec. 7, 1903.

778,897. Motor Control for Hoisting-Buckets. Lewis J. Robb and William M. Rosewater, Pittsburg, Pa., assignors to Heyl & Patterson, same place. Filed Dec. 19, 1903.

779,098. Electric Plug. Nelson H. Raymond, Brooklyn, N. Y., assignor to Stanley & Patterson, New York City. Filed April 13, 1904.

779,182. Combined Circuit-Breaker and Starting Rheostat. Robert H. Read, Schenectady, N. Y., assignor to the General Electric Company. Filed Oct. 28, 1903.

779,189. Power-Generating Apparatus. Elihu Thomson, Swampscott, Mass., assignor to the General Electric Company. Filed April 12, 1900.

779,190. Static-Influence Electrical Machine. Elihu Thomson, Swampscott, Mass., assignor to the General Electric Company. Filed April 12, 1903.

779,199. Motor-Controller. Charles E. Barry, Schenectady, N. Y., assignor to the General Electric Company. Filed Sept. 24, 1903. Renewed May 21, 1904.

779,206. Control System. Frank E. Case, Schenectady, N. Y., assignor to the General Electric Company. Filed Sept. 24, 1903.

779,249. Time-Circuit Controlling Apparatus. Johan M. Andersen, Boston, Mass., assignor of one-half to Albert Anderson, same place. Filed Dec. 14, 1903.

779,255. Current-Meter. Warren S. Blauvelt, Grosse Isle, Mich. Filed July 18, 1904.

779,265. Brush-Holder for Dynamo-Electric Machines. Fredrick M. Conlee, Madison, Wis., assignor to the Northern Electrical Manufacturing Company. Filed May 21, 1904.

779,267. Current-Controlling System. Arthur C. Eastwood, Cleveland, O. Filed Aug. 9, 1904.

779,320. Current-Motor. Gilbert Samuelson, Sandpoint, Idaho, assignor of one-half to Edward McGregor, same place. Filed March 26, 1904.

779,376. Automatic Magnetic Circuit-Breaker. William M. Scott, Philadelphia, Pa., assignor to the Cutter Electrical & Manfacturing Company. Filed May 27, 1899. Renewed Dec. 11, 1901.

Telephones and Telephone Apparatus.

778,877. Telephony. Albert Meinema, Chicago, Ill. Filed May 2, 1904.

779,004. Multiple-Transfer Switchboard. Charles B. Smith, New York City. Filed May 8, 1900.

Miscellaneous.

778,893. Galvanic Battery. Charles J. Reed, Philadelphia, Pa., assignor to the Security Investment Company. Filed July 12, 1901.

778,894. Process of Making Spongy Lead for Secondary-Battery Electrodes. Charles J. Reed, Philadelphia, Pa., assignor to the Security Investment Company. Filed May 7, 1903.

778,912. Dry Cell. Walther Stockigt, Greiz, Germany, Filed May 12, 1904.

778,971. Electric Burglar-Alarm. Franklin S. Holmes, New York City. Filed May 17, 1904.

779,003. Automatic Magnetic Circuit-Breaker. William M. Scott, Philadelphia, Pa., assignor to the Cutter Electrical & Manufacturing Company. Filed June 28, 1901.

779,054. Electric Generating Unit. Sterling Shaw, Jacksonville, Ill. Filed Aug. 29, 1899.

779,090. Thermo-Electric Element. Albert L. Marsh, Lake Bluff, Ill., assignor to William A. Spinks & Co., Chicago, Ill., a copartnership. Filed June 4, 1904.

779,153. Apparatus for Perforating the Type-Bands for Automatic Telegraph Transmitting Apparatus or the Like. Adolf Franke, Gross-Lichterfelde, and Erwin Ehrhardt, Berlin, Germany, assignors to Siemens & Halske, Aktien-Gesellschaft, same place. Filed Feb. 29, 1904.

779,223. Keyboard Telegraphic Transmitter. Maximilien Kotyra, Paris, France. Filed March 21, 1904.

779,231. Induction-Coil. John G. Meyers, East Providence, R. I., assignor to the Varley Duplex Magnet Company, Phillipsdale, R. I. Filed Aug. 4, 1904.

779,247. Apparatus for Testing Electrical Resistances. John B. West and Frederick M. Du Bois, Syracuse, N. Y., said Du Bois assignor to said West. Filed Jan. 2, 1904.

779,383-384. Electrolytic Apparatus and Process. Clinton P. Townsend, Washington, D. C. Original application filed April 12, 1902. Divided and this application filed May 10 and May 11, 1904.

Reissue.

12,301. Process of Electrolytically Refining Lead. Anson G. Betts, Lansingburg, N. Y. Filed April 23, 1903. Original No. 713,277, dated Nov. 11, 1902.

THE TELEPHONE WORLD.

Southwestern Missouri Independent Telephone Association Organized.

Representatives of Independent lines in the southwestern part of Missouri and the northwestern part of Arkansas met in Neosho, Mo., a short time ago and organized the Southwestern Missouri Independent Telephone Association. The following officers were elected: President, C. M. Robeson, Neosho; secretary, Dr. J. B. Hancock, Newtonia. Among those present were W. T. Stahl, Siloam Springs; J. I. Potter, Gravette; K. G. Comfort, Westville; W. D. Wessons, Springtown, and others.

Successful Indiana Company.

At the annual meeting of the stockholders of the Ft. Wayne, Ind., Home Telephone Company, the following officers and directors were elected for the ensuing year: President, Charles S. Bash; vice-president, John B. Reuss. secretary and manager, William L. Moellering; treasurer, Max B. Fisher; Charles S. Bash, J. B. Reuss, W. L. Moellering, M. B. Fisher, Isador Lehman, P. W. Smith, G. Max Hoffman, W. A. Bohn and George L. Fox, directors.

The annual reports, showed the end of the most prosperous fiscal year in the company's history. At the meeting 4,561 shares of stock out of 5,000 shares were represented. The stock is distributed among 127 persons, all but two of whom are residents of Ft: Wayne.

The report of the secretary showed 3,220 telephones in operation, a gain of 400 over last year. New telephones are being installed now at the rate of 50 per month. Upon the Home lines are more than 1,000 business houses in Ft. Wayne. The company now has nearly 200,000 feet of underground and aerial cable in service, and 25,000 feet has been added during the past year. It is the intention of the company to expend $15,000 in cable extensions and farm lines within the next six months.

Owing to the death of Judge James M. Thomas, the Portsmouth, O., Telephone Company has been reorganized by the election of the following officers: President, I. S. Grimes; vice-president, Joseph S. McKell, Chillicothe; secretary and treasurer, Dr. W. D. Temper; general manager, E. E. Knox.

The Citizens' Telephone Company, which has already a large number of subscribers in Meredith, N. H., will extend its lines to Meredith Neck in the spring and it is probable that a central office will be located in Meredith.

George W. Beers, of Ft. Wayne, Ind., has bought the Leavenworth, Kan., telephone plant. It has 700 subscribers and two toll lines, 26 miles long. Mr. Beers will at once modernize the plant at a cost of $150,000.

Since the incorporation of the Independent Telephone Company at Council Bluffs, Ia., a number of companies have signified their intention of making extensions to connect with the new system when it is established.

The president of the New Telephone Company of Indianapolis, Ind., has ordered plans for the erection of a new exchange building.

Independents Unite with Eastern Traffic Association.

Representatives of the Independent long-distance concerns in Western Pennsylvania, West Virginia and Maryland recently met in Cumberland, Md., and voted unanimously to join the Eastern Traffic Association of Independent Telephone Companies.

The accession at Cumberland means another link westward in the first attempt of the Independent people to give a transcontinental, or what might be termed interstate long-distance service in competition with the Bell Company. As a result of the new move, the long distance service of all the lines concerned will be controlled for an interchange of business; a uniform rate of charges will be established, and a uniform standardization of the system perfected. All money for long distance service beyond the territory of the respective lines will be forwarded to the proper exchanging companies, and in many ways an improved and enlarged service will be made possible.

Nebraska Independents to Meet.

The regular annual meeting of the Nebraska Independent Telephone Association will be held at Lincoln January 18 and 19. E. C. Hansen, of Fairbury, Neb., is secretary, and urges all Independents to attend.

The Farmers' Fountain Telephone Company was organized lately in Waterloo, Ill., and will soon begin the work of constructing three lines of 20 telephones each, all on one wire. The farmers will construct the line, and then divide the expenses among themselves. The cost of maintenance will be prorated. New Hanover is to be the central exchange for all these lines. Waterloo, Columbia and New Hanover will be the three towns connected by the lines. It is probable that the lines will be extended throughout Monroe County, should the system prove successful.

The farmers in Ponoco precinct, Saunders County, Neb., who want telephones have closed arrangements for connection with the lines of the Fremont Telephone Company. They are to put in their own instruments and set the poles and furnish the wires. The installing is to be done by the Fremont Company. The northeastern part of Saunders County has heretofore been without telephone communication with the towns and is tributary to Fremont.

A number of the leading financiers and telephone men of Lincoln, Neb., have been discussing the project of a new independent telephone line, which, if carried to completion, will take in Sioux City, Omaha. Lincoln and Denver. M. H. Spere, of the El Paso Telephone Company, and a promoter of several other lines, have been talking the matter over.

The Consolidated Telephone Company has completed its line to Lebanon, Pa. This gives the company direct connection to that place and Harrisburg. Arrangements are being made to build a line from Pottsville to Hamburg. This will give the Reading exchange a new outlet to the northern coal fields.

Youngstown Company Makes Extensions.

The Youngstown, O., Telephone Company has completed several important extensions to its local telephone service which puts it in a way to give its patrons better service than ever before. The new lines have been put up to Sharon and Greenville of No. 10 copper metallic circuits. A private branch exchange has been put into the office of the Youngstown & Sharon Railway Company, and a deal has been closed for a private line to the Bessemer limestone quarries near Lowellville. About 10 stations are attached through the exchange in the Youngstown & Sharon office.

During last year the Youngstown Telephone Company has put in 800 new telephones, that number being about evenly divided between business houses and private houses. Quite a number of farm lines have been put in and several toll lines have been added to the former list. The latter included one to Canfield. The new Sharon and Greenville lines give direct connection from Youngstown to many towns in Western Pennsylvania and New York State. Men are now at work on a new line along the Salt Springs road, which will connect several farm houses with the local exchange. The company closed last year with a total of not less than 3,000 telephones in its Youngstown district.

More Rural Telephone Lines.

A regular network of telephone lines is being constructed in the southern part of Bourbon and Crawford Counties, Kan.

Seventeen rural 'phone lines now run to the town of McCune from every point of the compass. The latest line has just been completed. Two additional lines will be constructed north and west from McCune in the near future.

The telephone company which was organized in the Buzz corner neighborhood in Sheridan Township of Crawford County, will run a line of poles to Cherokee, instead of putting the wire on the poles of the No. 1 line.

Two new telephone lines from Arcadia to Englevale. one running west, the other south by Coalvale are being worked up. The new line from Drywood is headed toward Pawnee.

A new line will soon be in operation between Arcadia and Harrisburg. Another line is being constructed from Arcadia to Girard and Swarts.

The Greenbush-Walnut Telephone line was lately brought into Walnut and connected with central. The line extends from Walnut to Greenbush and McCune, with exchange privileges on the St. Paul line.

The Central Union Telephone Company is laying a cable across the Illinois River at Beardstown, Ill.

The Wisconsin Independent Telephone Association will hold its meeting in Milwaukee January 25-26.

Telephone Incorporations.

The Clay County Telephone Company, Montpelier, Miss. Capital stock, $1,000.

The Howardsville Telephone Company, Lena, Ill. Capital stock, $2,500. Incorporators: Edward Fisher, G. W. Davis and E. A. Howard.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Camden, O.—The Camden electric light plant and all stock has been sold to E. C. Eikenberry for a consideration of $3,000.

Chariton, Ia.—The city council will rebuild the electric light plant at a cost of $40,000.

Clayton, Ind.—The Clayton Milling Company has purchased the Cloverdale electric light plant and will remove it to this city.

Edgar, Neb.—Keefe & Larkin have secured a franchise for lighting this city with electricity. A new plant will be constructed.

Forsyth, Mont.—The council has let the contract to J. E. Edwards for lighting the town for a period of 20 years, at a cost of $1.20 per year for each light.

Green Bay, Wis.—The county asylum trustees have planned to install an electric lighting plant in the asylum.

Houston, Miss.—It is reported that this town is considering the erection of an electric light plant. The town clerk can be addressed.

Ironton, O.—The installation of an electric lighting plant at the city waterworks is being considered by the board of public service.

Jonesboro, Ark.—It is proposed by J. F. Gautney to construct an electric plant for the transmission of electricity, a distance of 100 miles, for lighting railways and other purposes.

Leon, Ia.—Curtis & Chase, the new owners of the electric light plant, will have it inspected by an engineer, with a view to overhauling and improving it.

Little Rock, Ark.—The installation of an electric light plant is said to be contemplated by the Retail Grocers' Ice Company.

Madisonville, Ky.—A new electric light plant is proposed. Henry Oliver, of Fulton, is at the head of the enterprise.

McComb, Miss.—The McComb City Electric Light & Power Company with a capital of $50,000, has been incorporated.

Mendota, Ill.—An electric light plant, owned by Lathrop & Fahler, was lately destroyed by fire.

Mexico, City, Mex.—Considerable improvements are being made in the electric light plant. George Weddill is general manager.

Milwaukee, Wis.—Bonds will be set aside for the erection of a $400,000 electric light plant for this city.

Piedmont, Mo.—The electric light plant at this place was recently destroyed by fire.

Reinbeck, Ia.—Henry Nissen contemplates enlarging his electric light plant, and adding another dynamo.

Rising Sun, O.—The city council has granted a franchise to A. C. McMillen to build and operate an electric light plant here.

Saugatuck, Mich.—The Saugatuck Light & Power Company is to be incorporated by Charles A. Floyd and B. Van Raulto, of Holland, to establish an electric light and gas plant here.

Savannah, Ga.—This city has under consideration the erection of an electric light plant. Address the mayor.

South Bend, Ind.—The electric light plant was damaged by the blizzard last week to the extent of $2,000.

Washington, Pa.—The Washington Electric Light & Power Company on January 1 reduced the rate for domestic light one-third.

Zionsville, Ind.—An effort is being made by a number of enterprising citizens of this place to establish an electric light plant here.

STREET RAILWAYS.

Bloomington, Ill.—The Springfield, Lincoln, Bloomington, Pekin & Peoria Electric Railway Company, of this city, has changed its name to the Springfield & Northwestern Railway Company. Its capital is increased from $300,000 to $900,000.

Brownsville, Tenn.—A franchise has been granted to resident parties of this city for installing an electric car system here

Chillicothe, O.—The county commissioners have granted the Springfield, Washington C. H. & Chillicothe Traction Company a franchise.

Cleveland, O.—Myron H. Wilson, treasurer of the Cleveland Trust Company and Jacob H. Schmidlapp, president of the Cincinnati Union Trust Company, have been appointed receivers of the Central Market Street Railway Company of Columbus, O., the Dayton, Springfield & Urbana Electric Company and the Columbus, London & Springfield Street Railway Company, all owned by Arthur E. Appleyard, of Boston. The receivers were appointed with the consent of the companies.

Durand, Wis.—There is talk at Rock Elm of a trolley line to be built from this city to Ellsworth, passing through the former place.

Fort Smith, Ark.—It is reported that the Fort Smith Electric Street Railway Company contemplates expending $180,000 in improvements, including the erection of a power house.

Huntington, Ind.—The Huntington, Columbia City & Northwestern Railway Company has been incorporated with a capital stock of $25,000. The line will be run from this city through six cities to Lagrange.

Newark, N. J.—Judge William M. Lanning, of the United States District Court, has appointed Edwin C. Foster receiver for the New Orleans Railways Company. The application was made on behalf of the New York Security & Trust Company.

New Haven, Conn.—The sale of the New York & Stamford Electric Railroad to the New York, New Haven & Hartford Railroad Company for $1,000,000 is officially confirmed.

Niles, Mich.—F. M. Gray, a capitalist of this city, has started a movement to form a company and build an electric line west from Buchanan to Michigan City, Ind.

Wichita, Kan.—The Wichita Railroad & Light Company has decided to enlarge its power house and plant to over twice its present capacity.

POWER PLANTS.

Canton, N. Y.—The St. Lawrence Transmission Company has been incorporated with the Secretary of State, to generate, buy, sell, transmit, use and deal in electricity for producing light, heat or power; also to carry on the business of lighting by electricity or using it for heat or power in various localities. The capital stock is $25,000. It is proposed to carry on operations in the towns of Massena, Louisville, Norfolk, Waddington, Madrid, Norwood, Potsdam, Canton, Rensselaer Falls. Heuvelton, Richville. Hermon, Morristown, Gouverneur, Edwards and Talcville, and the city of Ogdensburg, all in St. Lawrence County.

Lockhart, S. C.—The Broad River Light & Power Company has been incorporated with a capital of $1,000,000 by J. L. Davis, M. V. Haselden and others, to develop power in this place.

Manitowoc, Wis.—Work will be started at once on a $200,000 electric plant for furnishing power and heat, the West Side Electric Company, of which Mayor William Bahr is head, having been granted a franchise.

Pittsfield, Mass.—The Pittsfield Street Railway Company is to build during next season a power plant. Its growth and development of new lines necessitate a plant of its own.

BIDS WANTED.

Little Rock, Ark.—Sealed proposals will be received by the board of public affairs for this city until 12 o'clock noon, January 18, for the building of an addition to the city electric light building according to the plans and specifications on file in the office of the superintendent of public works, at the city hall, and the erecting and installing of a 350 hp. boiler and equipment, according to plans and specifications on file in the office of the city electrician at the city electric plant, same to be paid in city warrants, one-half cash, upon completion and acceptance of the work, and one-half due July 25, 1905. The board reserves the right to reject any or all bids. Address Board of Public Affairs, care of F. M. Oliver, Clerk.

Birmingham, Ala.—The Kennedy Stave & Cooperage Company, of this city, is in the market for a 14 by 20 automatic engine, and two 72 inch by 16 foot tubular boilers.

Carrollton, Ga.—The Carrollton Electric Company, of which J. G. Cheney is secretary and treasurer, wants a 40 to 50 hp. engine.

Cumberland, Md.—The Footers' Dye Works here is in the market for power, electrical equipment and supplies.

Dawson, Ga.—A. J. Baldwin & Co., 102-4 Main street, this city, is in the market for a new or second-hand Corliss engine, 14 by 42 inches.

Hattiesburg, Miss.—The People's Ice & Coal Company of this city wants one 200 hp. Scotch marine boiler.

Lebanon, Va.—L. L. Bays & Sons, of this city, are in the market for electric lighting apparatus.

Mount Olive, N. C.—The Bell Lumber Company of this place wants prices on a new and second-hand 60 hp engine, and 80 hp. boiler.

Neck, Mo.—The North Fork Lead & Zinc Company want prices on a 100 hp. boiler. Address Jesse Roberts, general manager, Lock Box 23, this city.

Newcastle, Pa.—The Sample Agency Company, 20 Pittsburg street, is in the market for one 100 hp. engine (reversible), and one 150 hp. boiler; also a gasoline engine.

Wheeling, W. Va.—Henry Schmulbach, of his city, wants prices on generators.

NCTES FOR INVESTCRS.

An increase in the dividend rate on Electric Company of America (Philadelphia) is looked for at the meeting of directors this week.

Mayor McClellan asserts that New York city will build its own lighting plant whether or not the Legislature passes the city lighting bill.

At the annual meeting of the Boston & Lowell Railroad Corporation the stockholders re-elected the directors and approved an issue of $500,000 bonds.

The Omaha Electric Light & Power Company has declared the regular semi-annual dividend of $2.50 per share, payable February 1 to stockholders of record January 20.

The State Department at Harrisburg, Pa., has granted a charter to the Commonwealth Electric Company of Philadelphia, with a capital of $100,000 to furnish light, heat and power to the city of Philadelphia.

Philadelphia Electric shares were adversely effected by the chartering of the Commonwealth Electric Company, and Philadelphia Electric is now 10 per cent. below the high price two weeks ago.

W. J. Ferris, of the General Electric Company, has purchased the plant of the Independent Light & Power Company of Quincy, Ill., from J. W. Cassidy. The price paid was about $200,000.

The New Haven Railroad pays $1,000,000 or $125 per share in 4 per cent. bonds of the Consolidated Railway Company for 8,000 shares of the New York & Stamford Electric Railway Company.

A $5,000,000 mortgage given by the Niagara, Lockport & Ontario Power Company in favor of the Standard Trust Company of New York was placed on record in the county clerk's office in Lockport, N. Y., last week.

The presence in this city of J. J. Mitchell, president of the Illinois Trust Company, and important members of the Chicago group interested in the Chicago Union Traction Company, is expected to lead to important conferences with the Eastern interests of the company, represented by H. B. Hollins & Co., looking to settlement of the Chicago traction tangle.

It is stated that the United Electric & Power Company of Baltimore has purchased from Berton, Storrs & Griscom, of New York, a majority of the stock of the Consolidated Gas Company of Baltimore. This is the first step in the plan which contemplates a consolidation of the United Electric Light & Power Company and the Consolidated Gas Company. It is thought that the total capitalization of the reorganized company will exceed $30,000,000.

The decline in New York Metropolitan stock is a matter of poor earnings. The last nine days in December the subway carried 318,000 passengers daily, and in the same time the Manhattan Elevated traffic fell off 40,000 passengers per day. This leaves 278,000 passengers to come from somewhere. The question now rises how much traffic must Metropolitan be losing? More subways are to come. The new Interborough City Railway Company has obtained a charter to build six trolleys in the Bronx, and will do business on transfer to existing subway lines at 8 cents per passenger. Thus it looks as if money expended by the Metropolitan in the Bronx district will, for some time to come at least, be an unprofitable investment.

EDITORIAL NOTES.

Why Brooklyn Bridge Must be Rebuilt.

An original investment of $15,000,000, which, with attention and care, has reached $20,000,000, represents the money spent on Brooklyn Bridge. Once the pride of the metropolis and the wonder of the world it is now reaching a period in its history when the paramount question of danger overrides all other considerations and the structure must be rebuilt to insure public confidence and safety. Its rate of deterioration has been $1,000,000 a year, which the engineering experts have attributed to the causes of overstrain and electrolysis. Overstrain perhaps was to have been expected of the only direct connecting link between two great cities; but electrolysis as a cause of destruction to so noble a structure represents a certain knowing heedlessness on the part of trolley companies whose experiences should have called for some provision on their part against such disastrous consequences. Let means be taken to prevent similar destruction of the new bridges further up the river.

* * *

Coal Combustion for Gas and Steam Plants.

Theories tickle the imagination, but facts produce a healthier stimulation of the faculties. In theory a gas engine electric light plant is ideal, but the question is often asked, How is it in practice?

Here are the facts: Two electric plants were compared, one operated by gas of 685 hp., the other by steam of 1,250 hp. capacity respectively. Each plant ran from 15 to 18 hours a day. The statistics at hand after a six months' run show a heat consumption for the steam plant of 92,000 British Thermal Units per kilowatt hour and for the gas plant a heat consumption of only 29,100 B. T. U. per kilowatt hour. This shows a reduction comparatively to nearly one-third—the ratio of 29,100 to 92,000. In the instance recorded the coal from which the gas was obtained averaged up about 13,000 B.T.U. per pound. The richer the coal in heat units the less the weight required per kilowatt hour and the cheaper, comparatively, the power produced.

The startling results shown in this test are the strongest possible advocates for a radical change in power-producing methods—particularly those employed for the production of cheap electricity. Where plants are to be installed near fuel centers no argument against a gas installation is possible. It is only when installations are far away from coal fields that the cost of coal reduces the significance of the foregoing results.

* * *

Does the Public Buy Light or Electricity?

The agitation of questions of general public interest has been the means of awakening public consciousness to the true meaning of certain technical situations—the result of which has been, in most instances, an improvement, in an economical or financial sense, of great public benefit.

The desires of municipal leaders are not always in harmony with the expressed opinion of the public. As advisers the municipal representatives may be correct, but much of their influence as public benefactors depends upon the various phases of the subject which can be presented by argumentative antagonists as a means of overruling such suggestions.

Such a condition of affairs presents itself in those cases where the public buy electricity for electric lighting and are supplied with lamps to use this energy, and find, when it is so utilized, the lamps do not give their proper quota of light.

This is not the situation in large American cities, but it is often the case in small towns, thousands of which enjoy the advantages springing from the use of electricity for light and power. The question naturally arises in relation to such cases where power is received after covering considerable distance, whether the sale of electricity for lighting ought not, for the protection of customers, be best considered as the sale of *light*. What a man actually buys or wants to procure when he uses electricity is not the electricity itself but light. This, therefore, is a basis which would yield better returns to both parties in the end than the practice now observed, for obvious reasons.

These reasons are as follows: First, the public want the light—just the same as the city lighting is contracted, on the basis of a given amount of light for a given period of time; second, the lighting companies are at liberty to choose the lamp they please for generating light. This, of course, gives them considerable freedom, because if they employ a lamp which takes less power and gives the same light, they make more profit on the sale of power.

If it were now possible for a lighting corporation to introduce successfully, for general use, a two watt lamp instead of a three and a half or three watt per candle power, the capacity of the plant would be directly increased one-third, without any greater increase in expense other than that required for the installation of services to the new points of consumption.

Perhaps the future will show that the sale of light is the most logical and unquestionably the most modern course for the lighting companies to follow. While it might be argued that it amounts to the same thing in the end, yet, under such circumstances as those suggested, the necessity imposed upon lighting companies to devote their interest equally to the production of cheap power as well as cheap light would lead to the invention of a practical low watt lamp. Legislative enactment may limit the cost of electricity, but progress in the field of new sources of illumination will make such laws futile, at least in so far as cheap light is concerned.

* * *

Mont Blanc's Electric Railway. An electric railway to take passengers to the top of Mont Blanc, the highest mountain of the Alps, will be built by a company formed in Paris. The estimated cost of the road is $2,000,000, and a cable dispatch says the money was all paid in by the stock subscribers last week. The engineers have made plans to obtain the necessary electrical energy from some of the numerous waterfalls to be found in the locality. Instead of paying $60 for the services of guides to make the ascent, the cost for the trip on the electric railway will be only $10.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

Chicago is credited with selling $13,000,000 worth of electrical apparatus last year.

Comptroller Grout of this city has engaged several electrical experts to assist him in his investigation into the cost of electric lighting supplied to New York.

The Faraday Society of Great Britain is to be congratulated on having Lord Kelvin for its next president.

The Allis-Chalmers Company is "gathering in" a number of brainy men from the big electrical companies.

The Young Men's Christian Association of Boston last week opened a school of applied electricity. Mr. William Smith, formerly of the Massachusetts Institute of Technology teaching staff, will deliver a series of lectures.

United States Consul Bliss at Venice informs the State Department that there is a great demand in that city for electric launches and electric appliances.

It is stated in Pittsfield, Mass., dispatches that the Stanley Electrical Company of Pittsfield and the General Incandescent Arc Light Company of New York have been consolidated.

Arrangements are being made for the installation of wireless telegraphy on the New York Central and Lake Shore railroads.

Judge Kavanagh of Chicago has appointed Edward Bemmer receiver for the Whitney Electrical Company, which is capitalized for $56,000,000, to promote the alleged inventions of Albert Gallatin Whitney. His bond was fixed at $500. The petitioners allege the assets principally consist of "mythical plans and absurd inventions." One of the inventions, it is alleged, consists in "ejecting or shooting above and beyond the atmosphere of the planet commonly known as the earth four brass balls, which are supposed to gently and peaceably remain beyond said atmosphere after having been once shot or thrown up there."

The French Government is experimenting with a telautograph for the purpose of its adoption throughout France. The instrument sends a telegraphic dispatch, reproducing at the receiving end the handwriting of the sender.

The 247th meeting of the New York Electrical Society will be held in the lecture room of the American Institute, 19 West 44th street, this (Wednesday) evening, January 18, at 8 o'clock. Prof. W. S. Franklin, of Lehigh University, will lecture on "Electric Waves and the Reaction of Transmission Lines." The elementary physical theory of electric wave motion will be outlined and the mechanical analogies carefully developed.

An attempt is to be made soon to dissipate fog in New York Harbor. The method to be followed will be precisely that which Sir Oliver Lodge has adopted in his successful fog-dispelling experiments at Birmingham University, England. The electric current is shot up into the fog through barbed wires. The current is of great intensity—250,000 volts.

A cable dispatch from Rome, Italy, says the greatest interest exists in scientific circles there over the invention of a system of wireless telephone by a monk, Father Emilio de Carbogagno of the Monastery of St. John and St. Paul. On a terrace in the monastery garden the inventor has placed four masts, forming the corners of a square, each side of which is 4 meters in length. A series of wires running down the sides of the masts are joined in a little box placed upon a table in the center. Hanging beside the box, which acts as a receiver for the voice, are two ordinary telephonic ear pieces. At a distance of 250 meters, another station, it is said a conversation can be readily carried on between the two stations.

Work on a wireless telegraph station in the Brooklyn Navy Yard will soon be begun to enable Commander Robert E. Peary to keep in touch with civilization during his next attempt to plant the flag at the pole. At the navy yard it is said Commander Peary will erect wireless stations after he leaves the Labrador coast, to keep in touch with the nearest station on the mainland as he proceeds northward. From there communication with New York will be easy. As announced, the vessel of the expedition will be forced to the northern coast of Grant Land, where the party will go into winter quarters. This is only about 450 miles from the pole.

UNITED ENGINEERING BUILDING.

At a meeting of the conference committee on the United Engineering Building, held January 7, Mr. Alfred R. Wolff was unanimously appointed consulting engineer for the heating and ventilation of both the United Engineering Building and the Engineers' Club, to be erected at 39th and 40th streets under the Carnegie gift to engineering of $1,500,000. Mr. C. O. Mailloux was selected as the consulting electrical engineer for the United Engineering Building, and the firm of Bates & Neilson were selected as consulting electrical engineers for the Engineers' Club. All these gentlemen are well known in connection with the execution of large work of the class named in New York and vicinity, in addition to which they are prominently identified with the organizations that will occupy the buildings in question. Mr. Wolff and Messrs. Bates & Neilson are also members of the Engineers' Club of some years' standing, and Mr. Putnam A. Bates was for a long time district engineer for all the Crocker-Wheeler installations in the New York territory.

Preparing for the Convention.

We are assured that nothing will be left undone by the committees having charge of the arrangements for the convention of the National Electric Light Association, which will be held in Denver and Colorado Springs the week of June 6. These committees, our correspondent states, have made such excellent progress that they are able already to assure those who are planning to attend the best treatment ever accorded a convention in Colorado.

Scores of means of entertaining the members and visitors have been suggested. There have been so many, in fact, that the committee was compelled to begin selecting and drop-seeking for the means to provide diversions. This is assurance of the arrangement for the best of everything.

Members of the association and others who will attend the convention have written to the secretary and to members of the committees their approval of the selection of the Colorado cities, because of the excellent pleasure trip that is afforded through attendance upon the convention.

Denver and Colorado Springs committees, our correspondent states, are both busily engaged in making their plans. They have arranged for many side trips already, and will see that a large number of others are in the itinerary. Each of these trips will be perfect in every detail.

Electricity Versus Gas.

The above heading is the title of a pamphlet just issued by the National Electric Light Association for the use of its members who are threatened with Welsbach competition for street lighting. This paper was originally written by Mr. W. F. White for the 1900 meeting of the Ohio Electric Light Association. Mr. White has practically rewritten the paper and has brought it down to date by adding data recently collected from cities and towns all over the country. The pamphlet is illustrated with reproductions from photography showing graphically the difference in street illumination by the two methods. It should prove of great value to the members of the association.

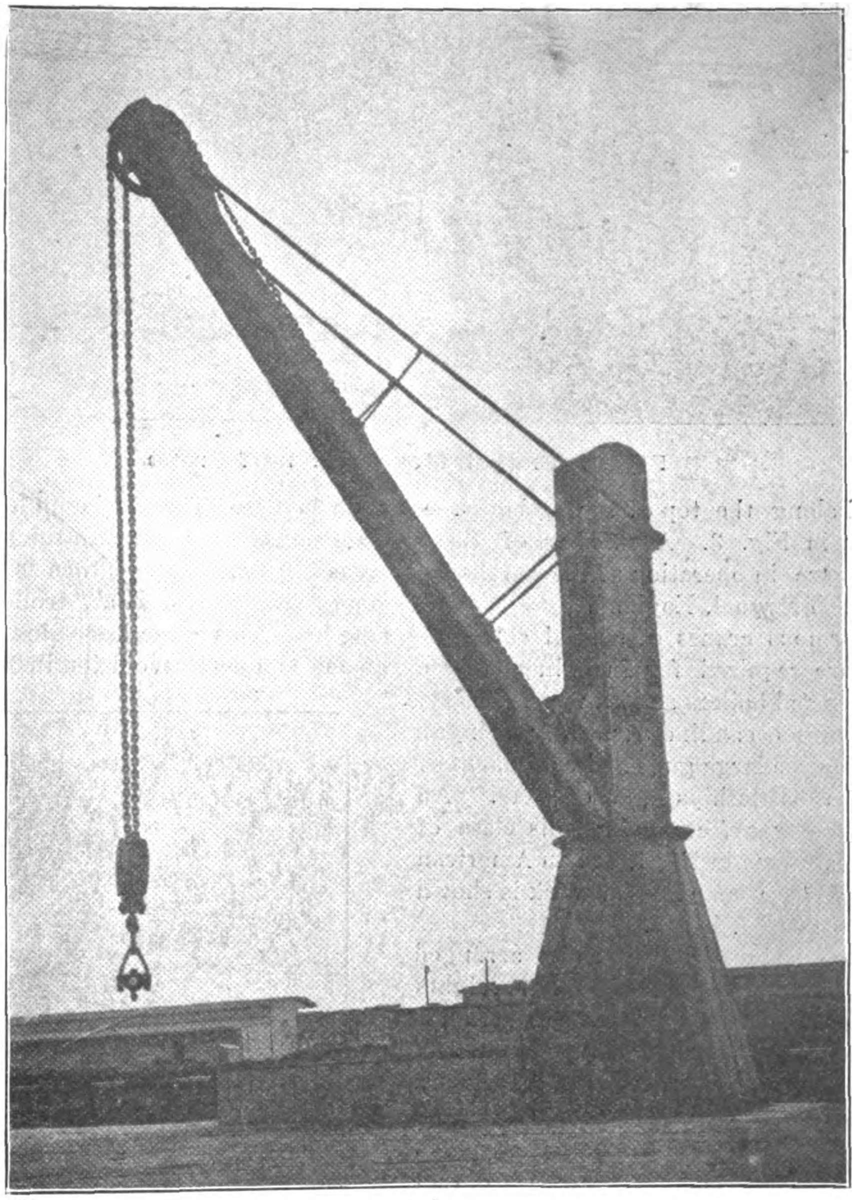

Fig. 1.—English Fixed Wharf Crane, 30 Tons Capacity.

MODERN HARBOR AND WHARF CRANES.

BY FRANK C. PERKINS.

Among the labor-saving devices utilized at the present day in the construction as well as for loading and discharging large vessels, none is more important than the wharf and harbor crane. Steam, hydraulic and electric power have been utilized extensively in Europe as well as in America for operating this class of machinery. In some cases the combination of electric power and hydraulic power is found most satisfactory. Fig. 1 shows a fixed hydraulic crane designed to lift 30 tons. It was erected at Rotterdam by Sir W. G. Armstrong, Whitworth & Co., while Fig. 2 illustrates a movable quay crane, constructed at the same works, having a pedestal with an opening through it large enough to allow men to pass with hand trucks. More than 100 of these cranes are in operation at the Royal Victoria & Albert Docks in London. Another type of movable hydraulic cranes, which greatly facilitates the loading and unloading of large vessels, is arranged to travel along the top of a warehouse, as shown in Fig. 3. A number of these cranes are in operation at the warehouse docks, Liverpool, England.

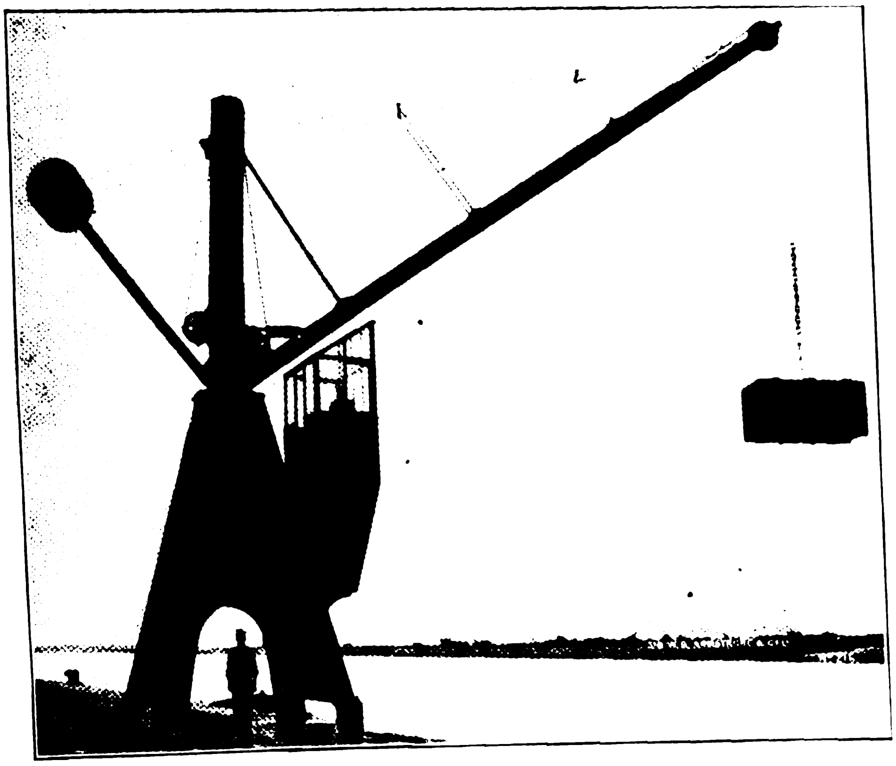

Fig. 2.—English Movable Wharf Crane.

Enormous cranes of special construction are required for installing marine engines and boilers and heavy machinery, in modern ocean liners and for placing in position the large guns and equipment of modern battleships and cruisers. An Austrian wharf crane for this class of work is shown in Fig 4, and an American crane for the same class of work is shown in the drawing, Fig. 5.

These heavy cranes are also arranged for a general loading of lighter weights at higher speeds. This latter function is of the greatest importance because as a general rule cranes built for heavy work will operate at a lower efficiency, and too slowly when used for lighter work, which forms the greater part of that carried on at an ordinary wharf. In busy shipyards cranes of the heavy type are not often required to move boilers and engines of from 50 to 150 tons weight and are therefore very often lying idle. The adaptability of these types of cranes to all kinds of work makes them unique and of special interest. The crane shown in Fig. 4 was constructed for the Steam Navigation Company of the Austrian Lloyd at Trieste by the Maschinenfabrik J. Von Petravic & Co., Vienna, Austria. This crane has a height of 34.14 meters at a maximum projection of 20.1 meters at the short jib with a load of from 35 to 170 tons and a maximum projection of 30.7 meters at the long jib with any load up to 35 tons. The maximum load of this crane on the short jib with the large trolley is 170 tons, while 50 tons is the maximum load for the small trolley on the long jib. This crane has a slowing speed of one complete revolution in 6 minutes, and all of the motions are obtained by a series wound electric motor. The maximum lifting speed of the small trolley is 3 meters per minute, the traveling speed being 20 meters per minute while the maximum speed of the large trolley is 8.5 meters per minute traveling, and .55 meters per minute for lifting, these speeds being for maximum loads while for smaller loads the speeds are proportionately faster.

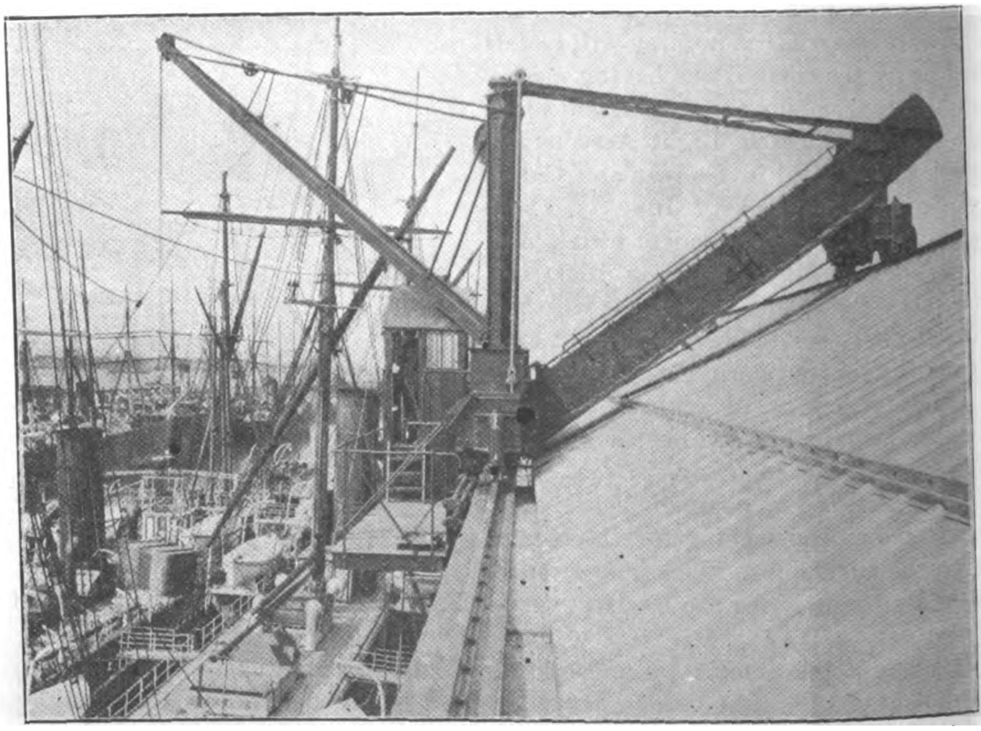

Fig. 3.—English Movable Hydraulic Crane.

The American folding jib crane of 75 tons capacity was installed by the Wellman-Siever Engineering Company of Cleveland, O., at the shipbuilding plant at Quincy, Mass., of the Fore River Ship & Engine Company.

This crane has a capacity of 56 tons for the main trolley, 28 tons for the auxiliary trolley and more than 11 tons for the lifting tackle. The longitudinal travel of this crane is operated at 57½ and 165 feet per minute, and the main trolley travels at the rate of 75 feet per minute, with a lift speed of 11 feet per minute. The auxiliary trolley has a lift speed of 22 feet per minute and a traveling speed of 150 feet per minute, while the lifting tackle operates at 25 feet per minute, and the boom hoist 21 feet per minute. This crane is utilized extensively in the fitting out of all classes of ships under construction in these yards, the storage yard being 1,200 feet in length and 150 feet in width. The fitting out dock, being 1,200 feet in length, will accommodate a number of large steamers, battleships and cruisers. The crane structure over the building slips is nearly 600 feet long and about 200 feet wide, with four high speed electric cranes in operation, each having a capacity of 10,000 pounds. Two of these cranes may be operated at the same time over each ship, with a total capacity of more than 10 tons.

Electric portal wharf cranes are extensivily employed in Germany and England as well as in the United States. The semi-portal electric crane is also utilized largely for loading and discharging vessels and are operated by steam and compressed air power as well as by electric power. The semi-portal or half portal electrically driven crane, noted in Fig. 6, was constructed by the Gesellschaft fur Elektrische Industrie of Karlsruhe, Germany, has a capacity of 4,000 kgs, with a range of 20 meters. The lifting speed is .50 meter per second a turning speed of 2 meters per second and a traveling speed of .25 meter per second.

A MULTIPLE-DIAL POTENTIOMETER.*

BY ALBERT CAMPBELL, B.A.

Some two years ago, in planning a low resistance potentiometer which I was building for myself, I was led to consider what would be the best construction, from the point of view, first, of ease of mechanical construction, and secondly, of accuracy, convenience of reading, and compactness. There seems no doubt that circular motion is easier to attain mechanically than rectilinear, and besides, a couple is applied with more ease than a single force, or, in ordinary language, a turning head is handier than a slider guided in a straight path. The latter requires much more movement of the hand and a steadier support for the instrument. Thus I decided on a thick slide wire, which could be bent into an arc of a circle, and a number of studs for the other contacts, the arrangement being as in Fig. 1, where A is a fixed resistance, on which to balance a cadmium cell, and V is the voltage to be measured, the whole a tolerably familiar construction. I wished, however, to have both convenience and accuracy, and accordingly decided to have 100 coils in the resistance at B. To have arranged these 100 coils all in one circle meant considerable mechanical skill and a great area of ebonite, but I found that both of these difficulties were got over by the device I proceed to describe; although very simple, I believe it is quite novel. Instead of arranging the 101 studs in one circle, I placed them in two sets as shown in Fig. 2 at C and D, but the last stud F on dial C was connected, as shown, to the turning head of dial D. Thus, when the slider of C has exhausted all its 50 coils, it arrives at F, and so switches the second slider into action on dial D. The switch-over stud F is marked blank, the other studs being numbered consecutively. Clearly the same principle can be applied to any number of dials, the only disadvantage of the method in its simplest form being that one must be careful always to read on the first dial that does not show a blank. This trouble may be avoided in various ways. When the sliders are fitted with number-disks, showing one figure at a time, it is not difficult to arrange that the reading of the second dial

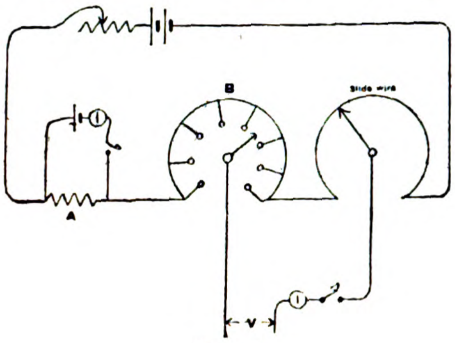

FIG. 1.

---

*From the "Electrical Review," London.

shall be kept hidden by the rim of the first disk, except when the first slider is on the switch-over stud F. In the actual instrument that I built, I got rid of all uncertainty by adding an interlocking arrangement, so that the second slider remains locked at its zero position until the first slider is turned to stud F; then, on turning the second slider onwards, the first is locked on stud F and cannot be moved until the second is brought back to its zero position again. The simple mechanism by which this is accomplished is shown in Fig. 3 (omitting irrelevant mechanical details). The two dials are fixed one over the other, and the sliders, S_1 S, are carried by concentric hollow spindles, whose heads N and P come close together in the hand. The spindles carry number-disks Q and R, the figures on the lower disk being visible through a hole in the upper one when this is in the proper position (on stud F); e and g are radial slots in the disks, and into these the double cam K works. Thus the only position in which both disks are free to move is when the two slots are together In all other cases one of the two sliders is locked. The result is that in handling the double head one passes smoothly and continuously from the one slider to the other. For the simpler construction, in which the slider axles are not concentric it is easy to modify the cam mechanism to suit. In conclusion, I may remark that the above device of multiple sliders can similarly be applied to a long slide wire subdivided into a number of sections.

The ore mills of Joplin, Mo., will be operated henceforth by electricity.

ELECTRICITY LEAFLETS.

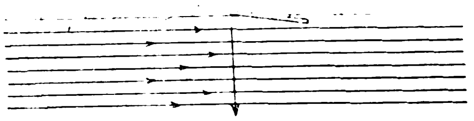
BY NEWTON HARRISON, E. E.

THE DYNAMO.

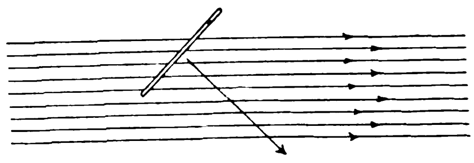
The Generation of Electromotive Force.—A dynamo is essentially a machine which generates electromotive force. The process of generating electromotive force, or EMF. as it is called for abbreviation, is by means of conductors moving in a magnetic field.

When mechanical energy is applied to conductors which are passed through magnetic lines of force in a certain direction, an EMF. is developed in them, which will be proportional to the speed with which they are moved, the number of conductors moved, and the strength of the magnetic field. The current produced in these turns or lengths of wire will be proportional to the EMF. generated and inversely proportional to the resistance. A dynamo, therefore, is a machine in which mechanical energy is transformed into electrical energy. A motor in contradistinction is a machine in which electrical energy is transformed into mechanical energy.

Both the motor and dynamo are mutually convertible into each other by the mere fact of applying either power in a mechanical or an electrical form. This identity of these two machines or types of machines has been of the greatest importance in the fields of practical work, particularly those of electric power transmission, transformation and distribution. A conductor may be moved through, or may cut lines of force at right angles to itself or by a motion of translation, as shown in the illustrations. If the field is the same in one case as the other, it is evident, that in covering a given distance the conductor will cut more lines of force in the first instance than in the second. It is only to be expected in such a case that the conductor cutting the greatest number of lines of force in a given period of time is the conductor generating the greatest EMF.



CONDUCTOR CUTTING LINES OF FORCE AT RIGHT ANGLES.

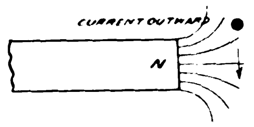


CONDUCTOR CUTTING LINES OF FORCE AT AN ANGLE.

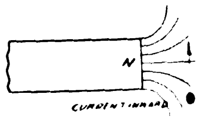
But there is another fact to consider, of the utmost importance in connection with this subject, and that is the character of the magnetic field in which a conductor or conductors are moved to produce EMF. If the magnetic field is uniform and the conductor when moved at a uniform rate of speed cuts through just as many lines of force per second in advancing as it has left behind, then no EMF. can be produced.

Variation in Field or Motion.—The physical law upon which the generation of electromotive force is based requires the absence of uniformity in the motion of the conductor through a uniform field of magnetism. The conductor must move in such a manner that the number of lines of force it cuts are constantly changing in number. In other words, it may be stated that the generation of EMF. depends upon a variation in the number of lines of force intercepting the conductor.

Motion of Conductor Downward.—The direction of motion plays a great part in the direction of the current in a conductor exposed to the influence of lines of force. The conductor when so affected develops positive and negative electricity at ends which reverse their polarity when the direction of the motion is reversed. For instance, if a conductor is moved downward in front of the north pole of a magnet the current will tend to flow outward from the paper. This motion of the conductor in a field, in which the movement causes a variation in the number of lines of force around it, is productive of E.M.F. The exact nature of the reaction which takes place, through which a closed electric circuit, when so moved in a magnetic field, is able to absorb mechanical energy and give out its equivalent in electricity, even if known, would have no influence upon the practical application of this principle in electro-magnetic machinery. Such knowledge would merely add another link to the chain which is being slowly forged in the physical laboratories of the world; connecting fact with fact and associating principle with principle for the purpose of showing the truth of great generalizations already made.



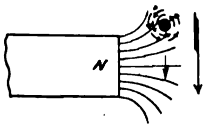
Downward Motion Current Outward.



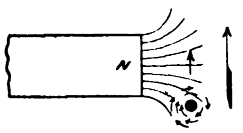
Upward Motion Current Inward.

Motion of Conductor Upward.—When a conductor is moved upward in front of the north pole of a magnet EMF. is generated. In this case the positive and negative poles of the conductor will be at such ends of the wire that the current with reference to the paper will tend to flow inward. Thus it is evident that an up and down motion to the conductor in front of the north pole would produce a series of electromotive forces which would be proportional to the number of movements per second, the strength of the magnetic field, and the length of the conductor in operation. There is this physical fact to note, in reference to such an experiment: that the reaction between the power applied and the magnetic field is very similar to the reaction between a sledge hammer blow and an anvil. The reaction throws the hammer off as mechanical energy, whereas the reaction between the conductor and the magnetic field, though not visible, still occurs in the form of an EMF. and current, which produces as startling a reaction if the proper means are taken to observe it as the hammer and anvil.

Direction of Field Around Inductive Wires.—A wire producing EMF. is acting as an inductor because an EMF. is being induced in it. The blow of a downward moving wire, upon the lines of force of a north pole produces a magnetic whirl around the wire, coincident with the generation of its EMF. and its polarity, or positive and negative ends. A reversal of the motion produces a reversal of the magnetic whirl around the wire, and of its electrical polarity and EMF.



Direction of Whirl Around a Downward Moving Wire.



Direction of Whirl Around Upward Moving Wire.

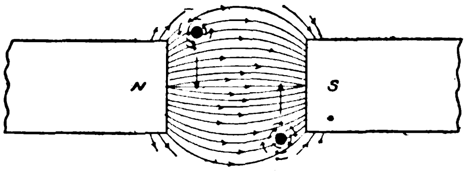
Motion, therefore, in a given field plays an important part in giving direction to the current as well as in governing the amount of EMF. developed. By this is meant that an up and down motion of a conductor in a field as shown would produce a current which would be constantly reversing; while, on the other hand, the rapidity with which the motion occurs would control the EMF.

If this experiment could be regarded as that of a stout metal rod striking a lot of projecting flexible steel wires it is easy to see that a downward and upward blow would make them coil around the rod in opposite directions respectively. There is this difference, however, that in the case of the metal rod, energy is consumed with each motion, while in the case of a moving conductor energy is consumed only in proportion to the current which flows. Consequently, if the conductor does not form part of a closed circuit only EMF. and no current results, and no energy is consumed. This fact is of importance because it shows that a dynamo on open circuit, although producing EMF., only takes from the engine enough power to overcome the requirements of friction at the bearings, commutator, etc.

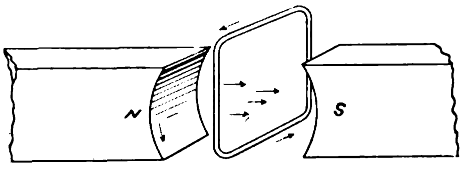
The direction of the magnetic whirl around wires moving in a magnetic field is an indication of the direction of the current in them. The presence of this magnetic whirl, however, acts as a deterrent to the motion of the wire. It is this which constitutes in a mechanical sense the reaction. In fact, it is impossible to produce a current in a wire by its movement through a magnetic field without experiencing this drag on the conductor.

Elements of a Dynamo.—If a north and south pole are now placed opposite to each other, the magnetic lines have a free path across to the south pole.

The direction of the lines of force from the north pole have not changed because of the presence of the south pole, in fact, they continue on their way unchanged into the south pole. A conductor moving downward in front of the north pole produces a magnetic whirl which is in the opposite direction to the whirl produced around the conductor moving upward in front of the south pole. This means that the current issuing from the first wire will flow in an opposite direction to that issuing from the second wire. If they were connected at their ends and then rotated around an axis instead of being individually moved up and down in the magnetic field, practically the same movement would be accomplished by circular motion.



Elements of a Dynamo.



Motion by Rotation.

In a dynamo this practice is followed out, and the result is that the conductors constantly produce a reversing or alternating current. Certain practical details require attention in this respect in order to outline the conditions resulting from such an arrangement in actual practice.

Alternating and Direct Currents.—First, it may be stated that there are two kinds of dynamos in use for electric lighting and electric power. They are called alternating and continuous or direct current machines. The difference between one class of machines and the other is entirely due to the fact that in the first class, the alternating current, the electrical energy is permitted to issue in the same manner as it is produced or generated. In the other class, the direct current, the alternations or reversals of current are rectified by means of a device called a commutator. This device is the means of causing all the impulses of current to be divided up into those which leave at the positive and those which enter at the negative pole. In other words, it sends out all positive currents from one pole of a dynamo and all negative currents from the other. The difference, therefore, between so-called alternating and direct current machines is not due to the fact that they generate different currents, because both develop alternating currents, but is due to the fact that the direct current machines have a commutator or rectifier and the alternating current machines have not.

The Calculation of EMF.—The meaning of the word current with respect to electricity has no significance unless associated with EMF.

The development of EMF. takes place under certain conditions in the case of a dynamo. There are three elements necessary, consisting of lines of force, conductors and motion. Cases arise in connection with alternating and direct currents where motion is not apparent. Yet it is there; if not visible, it must be the motion of the magnetic field. If a conductor is held stationary, and a magnet moved so that its lines of force cut the conductor, a parallel case is presented. But even in this instance the magnet is moved, whereas in those referred to the particular conditions allow only the magnetic field itself to move.

Value of One Volt.—The evolution of a volt in terms embracing the above conditions is carried out on the following basis: One volt is equal to the cutting of one hundred million lines of force by one conductor in one second. The conclusions to be drawn from this statement are obvious. If one hundred million lines of force must be cut by one conductor to generate one volt, then one-half as many cut by two conductors in one second or one-quarter as many cut by four conductors in one second will generate one volt, etc. From this statement is drawn the material for a very simple formula, by means of which the EMF. of a dynamo is calculated before construction takes place as follows:

EMF. in volts = number of lines of force × number of conductors × revolutions of the wire per second ÷ one hundred millions. Transcribing this formula into symbols for convenience:

$$E = \frac{L.\,F. \times S \times r}{100,000,000}$$

Where L. F. = lines of force.
S = conductors.
r = revolutions per second.
E = EMF. in volts.

To illustrate the application of this formula let L. F. = 5,000,000, S = 100 and r = 20, which represents 1,200 revolutions per minute. The volts would equal 5,000,000 × 100 × 20 divided by 100,000,000 which equals 100 volts.

ON BATTERIES WITH REVERSIBLE BOOSTERS.*

BY C. TURNBULL.

(Concluded from page 25.)

Size of Cells.—Given a booster with the above properties it is not difficult to arrive at the size of the cells. Thus, with an output of about 3,000 units per day of 16 hours we can do it with a generator which will do 200 kw. as ordinary full load, with, say, a 25 per cent. overload capacity to meet excessive and occasional rushes. As we can now get economical triple-expansion engines or turbines which will run economically for long hours at full load and that will give off overloads either by means of valve gear or by working as compound engines, this part of the problem is easily solved. We must then put in a battery which will be large enough to meet the maximum load of the station when running in combination with the generator. Where the hours of actual load are longer or shorter than the 16 hours mentioned above, or where there is little or no load during part of them, then the problem can be solved in a similar manner. Given, however, a booster which will work in harmony with its generator as above, the solution will not be difficult, and a good deal can be done by varying the hours of running of the generator to suit. In buying cells under maintenance, it should be arranged that the circuit breaker should be set as high as possible. This is really unobjectionable, seeing that heavy discharges are only momentary, and, further, the battery usually is not run down at all in working.

Type of Cells.—The actual work done by the cells when working with a reversible booster is very little. For although the curve of charge and discharge looks large enough in importance when it is examined on the recording ammeter chart, still the peaks integrate to very little. We, therefore, want a cell which will do with very heavy discharges, and also with considerable charges, but that does not necessarily have a large long hour capacity. Durability is more important than efficiency. As a matter of fact it is well known that a cell which receives charges and discharges at short intervals has an extraordinarily high efficiency, and a slight reduction in this if it gave increased durability would not matter. I have been informed by one of our leading accumulator firms that a cell to meet those requirements can be made and maintained at about half the ordinary price if it be asked for, and I hope that such will be on the market in the near future.

Space for Additions.—It is a great advantage to have the cell boxes large enough to allow of the addition of more plates. This enables the size of the battery to be kept down, as it is easy to increase its capacity. If, however, more plates are added, then it is not desirable to simply put the new plates in parallel with the old ones. Old plates should be taken from some of the cells to make up the additional number required in the other cells, and the cells thus depleted should be made up entirely with new plates. The space at the side is useful in assisting the much-desired circulation of the acid. It also enables the cells to be inspected by an inspection lamp on an L-shaped stick. This lamp put under the plates shines upwards and shows any shorts clearly.

Space at Bottom.—The space at the bottom of the cells should be ample, about 6 inches or so, so as to obviate frequent cleaning.

Number of Cells.—The possible variation of cell voltage is from 1.8 to 2.7 volts per cell, the last figure being obtained with the fortnightly overcharge, which makers recommend to be given to the cells. In ordinary working the variation is from 1.9 to 2.5 volts. Provided that the booster is arranged to prevent the current from coming back on to the generator, the number of cells may be varied considerably. I think, however, that 250 cells is a suitable number where the 'bus-bar pressure is between 500 and 550 volts. If fewer cells be used, a good deal of work is thrown upon the booster to pump the current out of them, and if more cells are installed there is a danger of the current coming back on to the generator if they be floated on the line without the booster when fully charged.

Instructions for Running the Battery.—This is a matter of great importance, and, unfortunately, battery makers usually give little resistance. It will be seen that it is necessary in working to insure that the battery has just the right proportion of current to put into it. Meters are of some assistance towards this end, but they must not be relied upon too much. It is doubtful if meters are quite accurate on the violently changing loads of a traction battery. Furthermore, it is likely that the effect of a discharge on the battery varies with the rate and also with the state of discharge that the battery is in. One hundred ampere hours taken out of a battery just freshly charged will not need the same extra percentage to be put back that the same amount would need from a battery well run out—at least, I think not; indeed, so long as the load is of such a kind that the battery gets a charge immediately after a discharge—as happens when working with a reversible booster—then the excess percentage of charge over discharge in ampere hours need be very little.

The advice is sometimes given that the booster should be worked so that the battery is charged every night at shutting-down time. This is impracticable without an undue amount of attention. The most practicable way that I have found is as follows: During the morning when the generator is started up, there is usually a slack time, so that it can be arranged that the battery is mainly charging. The battery attendant should be in the battery-room now, and he should go round and see that every cell gases up at the same time. He should watch the battery when it is gasing, and, at the same time, top up any cells with water if necessary. The water can be put in by a long glass tube, about 1½ inches in diameter, with a bell mouth. This will enable the water to be put in at the bottom, and it can be stirred about and well mixed with the acid. The amount of gasing and volts per cell necessary on the daily charge should be determined by the battery makers, whose assistance should be freely requisitioned at first start up. When the cells are full up, the attendant should inform the engine-room staff, so that the booster can be regulated, so that the battery can be discharged for a time rather than charged. When a little current has been run off, the adjustment can be made so that charge and discharge are about equal or as needed. This method of working the battery needs a minimum of attention and will be found very satisfactory in practice. Once a fortnight—if required by the makers—an extra charge can be put in, which will bring the voltage up to 2.6 or 2.7 per cell. This should be done at a quiet time, when the charge can be put in fairly steadily. The volts of each cell can then be taken on the top of the charge. The gravities of the cells can also be taken at the same time. The gravities can be relied upon to some extent to tell if the cells are getting their proper charge, but still these are affected by the addition of water to make up for evaporation. If a maintenance scheme is entered into, it should be on condition that the battery is to be worked on lines like this, and not on lighting battery lines.

---

*Paper read at the meeting of the Newcastle Section of the British Institution of Electrical Engineers, December 12, 1904.

Maintenance.—The question of the maintenance of batteries by makers is a thorny one. If the makers are good, substantial and decent people, then there is some assurance to the owner of the battery in having a maintenance. Otherwise, it may happen that after several years of maintenance have been paid that when repairs are needed the makers get out of their agreement by one of those curious clauses with which they fill their agreements. I mean, for instance, such a clause as that which states that the payments are to be made to the company without demand. It is possible to reduce the amount of the maintenance payment by stipulating for the battery to be kept up to, say, 90 per cent. of its original capacity instead of to the full capacity, and this is usually quite enough for reversible booster work. Indeed, with this proviso, the upkeep rate for a battery should be extremely low. The maintenance agreement should be settled as to terms before the order for the cells is definitely placed, as this will enable a better bargain to be struck. The user of the cells should then stipulate for six months' use of the cells before deciding whether to enter into the maintenance scheme or not. It is also desirable that the agreement should last over a long term of years—say 10—but with the user's option of terminating, say, after five years.

Water.—The question of water should be settled before the contract is placed. The makers usually stipulate for pure water only to be added to the cells, but if the town water is good this is allowed. If this is not good, then the user is in a quandary as to how to make up the evaporation. Condensed water from a boiler is not always suitable, as it may contain boiler compounds, if such be used, or iron. Makers do not always help in the matter. Thus I know of one case where the engineer asked them to provide a distiller to provide make-up water, and they offered one, after several weeks of correspondence, for about £400. Rain-water is often too impure. I think that a simple distiller could, however, be made by using a gas jet under a boiler. The steam would go through a worm, and would be cooled by water in a tank. After the worm had gone through this tank it would go through a second tank. The boiler and the two tanks would be connected by a pipe so that the water would stand in the same level in all. This would cause the boiler to be automatically fed with hot water. A tap could run into the last tank to keep up the level, and also to provide cooling water.

Battery-Room.—It is often stated that battery-rooms should be well lighted. Actually too much light in a battery-room is bad, as it renders cell inspection difficult. The room should be rather dark, with good artificial lighting. The wiring may be done on insulators. At intervals lamps should be provided on long flexes of Lyric 3 25 R.C. wire for looking into the cells from above. Hooks should be provided to hang these lamps on when not in use. I have found acid-resisting paint liable to chip off a concrete ceiling, but wood varnished with acid-resisting varnish has stood better. The ventilation should be good, but of a nature to prevent flies and dust from coming in too freely.

Milking Booster.—This should be run off the lighting circuit so as not to be shut off if the main circuit breaker of the traction generator is blown. It is a debatable point as to how the leads should be run for milking up the cells. In the diagram, I show them run under the grating on the floor, being supported on insulators. The flexible leads can be connected by means of screwed plug handles. A small switchboard can be fixed in one end of the room, or possibly in a small room provided for the purpose. Where the cells are on two floors the switchboard should be provided with one pair of switch fuses only, to connect either the upstairs leads or the downstairs leads on to the 'bus bars. The use of a single pair of switch fuses prevents any attempt to milk up two parts of the battery at once, as, of course, only one pair of flexible leads is kept in a room. The booster can be put in a convenient place, but the regulation of its volts can be done from the battery-room. The booster may also be arranged to provide heavy currents for meter testing purposes. The board should have a polarized ammeter and a voltmeter with paralleling and other stops on the switchboard.

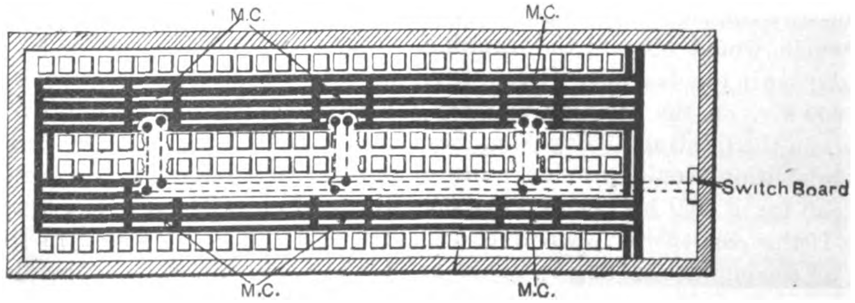


Diagram showing Arrangement of Trolley Wire Conductors for Milking-up Cells. The Grating is shown Broken Away to show the Trolley Wire which is underneath. M. C. indicates Movable Coves by which Plugs are got at.

Grating.—The grating for the battery-room floor can be made of rough wood dipped into melted pitch. This makes quite a cheap and satisfactory arrangement.

Reversible Booster Switchboard.—The breakers, of the booster motor and battery, should be on the live side, but most of the rest of the instruments on the board may be on the earth side. The motor breaker should be arranged to shut off the battery current, if it comes out so that the booster may not race owing to the battery current running through it. On the other hand, it is desirable to have the breakers arranged so that the blowing of the battery breaker does not stop the motor.

Meters.—Wattmeters may be used with the shunts taken off the 'bus bar, so that they virtually become ampere-hour meters. I have tried oscillating meters, which have the advantage that they do not need any pawls to stop them from running reversely. I think that mercury electrolytics or some shunted ampere-hour meters with a small drop might be used. One shunt would do for both. In this case the auto switch for putting either one or the other in circuit, according as the battery was charging or discharging, would be simply a mid-zero ammeter type of instrument, only that the pointer would have a contact on the end. This contact would swing up against one or the other of fixed contacts, and so direct the current into the right meter.

Testing of Meters.—It is not essential that the integrating meters should be absolutely correct, but it is essential that they should agree with each other, or that their differences should be known. They can easily be tested for this by simply reversing the connections of one so that they both read for charge, or discharge, for a day or two. The readings thus got will show whether the meters are agreeing.

Shunts.—The abomination of several shunts in series—one for the ammeter, one for the recorder, and one for the integrators—should be avoided. One shunt should do for the lot, or if two in series be used, then the instrument having the heaviest drop should come off the combined resistance of the two shunts. In this latter case the two shunts in series should be soldered together, so that the combined resistance could not be affected by bad contact.

Arrangement of Plant.—In some stations I think it would be a good thing to couple the booster right on to the main generator shaft, so as to save motor losses. In many cases I think it would be well to run traction and lighting dynamos in tandem on the same engine.

Where a reversible booster was in use, the load on the traction generator would be steady enough to prevent flickering on the lighting boards due to variations in the engine speed. Two ideas are possible—either the generator can be looked on as a traction generator, in which case the traction dynamo would be equal in capacity to the engine, and the lighting dynamo would be equal to the day load on the lighting board; or the lighting dynamo can be of the engine capacity and the traction one smaller. At night or on the peak loads, of course, when desired the loads could be separated out. The lighting dynamo could have the mid-wire connection through choking coils, which would obviate the running of a balancer in the daytime. Given, say, some 200 kw. on the traction and, say, 100 kw. on the lighting all day long, then the combination would provide quite a good load for a 400 kw. or 500 kw. engine. If the condensing plant were run direct off the engine shafting by chain or other gearing, we would have a very economical omnibus plant for many stations. Of course, one may say there would be a lot of eggs in one basket in case of breakdown, but then plant does not break down now as it used to, and, of course, the ordinary stand-by plant would be necessary as it is now. The amount of current that runs to waste nowadays in running balancers and motors for various purposes is so enormous that it is worth while to do something to save it.

Conclusion.—I have written this paper at somewhat short notice, although, of course the subject has been in my mind for a long time. Had I had more time it would have been possible to provide more diagrams, but I hope that the absence of them will not be unduly felt. Indeed, the style of the diagrams necessary to illustrate a paper of this kind is so well known that it is doubtful if they are necessary. I can only hope that the contents of the paper will be useful and interesting to all concerned in matters of this kind.

AN INTERPLANETARY TELEPHONE.

(Editorial in New York Times, Jan. 15.)

The actual achievements of electricians in the modern period have been so marvelous, so outrunning the wildest dreams which the imagination could have pictured for them, that, no matter what those magicians say they can do, the world, not allowing itself to be affronted with any reach of extravagance, is bound to stand still and listen. Mr. Nikola Tesla has such a score of electrical achievements to his credit that when he tells us he is going to wake up Mars one of these days, and possibly some other planets, with an oscillator of ten million horse power which he is getting up, we are obliged to take the statement into more or less serious consideration.

The instrument, according to his declaration, presents no unusual difficulty. He says he can make one representing a much higher power, say that of a thousand million horses, and with this some foundation is given for the belief that he can do with the world and the whole planetary system pretty much what he likes. Such a scheme fatigues the lay imagination, exhausted with previous surprises of all kinds which the inventing electricians have prepared for it, and it is not easy to say in the first shock of wonder attending the declaration what the world and its societies, near and far, all very much interested in the matter, ought to do about it. Confiding such a large force to the will and discretion of an individual, or even of a consolidated stock organization, looks rather perilous. It seems as if the stability not only of the cloud-capped towers, the gorgeous palaces, and the solemn temples, but of the great globe itself, with even some of its outlying siderial sisterhood, would in such case stand in much peril.

Such a force as Mr. Tesla names outruns the widest reach of mundane conceptions. The idea presents to the mind a sublime image of disturbing forces in action; shows how their potencies lie bosomed in the stillness and calm of the universe; but there is nothing attractive about it, and it promises no usefulness of any kind. The fancy of conversing with supposititious inhabitants of our next-door planetary neighbor has taken strong hold on the minds of electricians, astronomers and others in recent times, but when we come to think about it, what possible good could flow from opening communications with that lurid star, shedding its trails of fire and dews of blood, and carrying around in its revolutions a population which we might not like to have anything to do with? The best wish that can be made for Mr. Tesla's intentions and inventions in that direction, is that they will not come to any substantial result, as they probably will not. Mars will no doubt go on in its old courses, not heeding any of our signals, and in no increased degree "subject to the Constitution of the United States," whether Mr. Tesla turns his batteries on it or not.

Of more mundane possibility seems his invention of a torpedo which will go by itself any distance with unerring aim and blow the biggest warship into smithereens in a jiffy. This he thinks is destined to put a stop to the building of such vessels everywhere, and also render useless everything in the nature of fortifications existing in the world. If his invention had only been a little further advanced it might have helped the Japs to capture Fort Arthur in a forenoon, instead of being the better part of a year about it.

With predictions of so much confidence and grandiosity from those who have really wrought miracles in their electrical craft to make the exploits of Simon Magus and the Sorceress who contended with Aaron seem the cheap wonders of a side show, the only thing the public can do is to sit still and wait, disciplined in the experience that the highest expectations sometimes blow over, as on the whole it is well they should.

The National Automobile Exhibition.

Last Saturday night the fifth annual National Automobile Exhibition was opened at Madison Square Garden in this city, and thousands of spectators and admirers of the auto were present.

Two hundred and fifty exhibitors are represented in the show. Fully fifty more applied for space and had to be refused owing to lack of accommodations. Those who did succeed in getting space had to be content, in every case, with one-third of the display-room asked for.

There are 100 exhibitors of machines

of all sizes and kinds, from the runabout to the touring car. Each of these shows on an average three autos, making a total of 300 machines on exhibition. They range in price from $650 to $6,200.

The electrical effects this year are in keeping with the other improvements, and are better and brighter than at any previous show.

The exhibition will continue throughout the week, winding up with the annual banquet of the Automobile Club of America on Saturday night.

Electric Vehicle Company Wins Important Suit.

Suit against the Panhard & Levassor Company, prominent French automobile manufacturers, has been pending under the basic Selden United States patent for the past year. This suit has been decided against the Panhard Company. Hereafter all automobiles imported by the company will be under license from the Electric Vehicle Company.

Simultaneously is announced that all Mercedes, the celebrated foreign make of automobiles, will be imported under license from the Electric Vehicle Company. There are now 31 American manufacturers licensed by the Electric Vehicle Company under the Selden patent, and nine licensed importers.

Pittsburg to Have $50,000,000 Subway.

It is announced that H. C. Frick has completed plans for a system of subways to the suburbs of Pittsburg, including tunnels under both rivers to Allegheny and the South Side. The plan also includes the erection of a new skyscraper and a terminal for the Pennsylvania Railroad. It is said that Postal Telegraph interests are also involved, and that the company will remove its headquarters from New York.

Wants a Receiver.

Merle J. Wightman, of New York, has filed a bill in Chancery, at Trenton, N.J., asking that a receiver be appointed for the Pyro Electric Company, of which he is vice-president and the owner of 1,118 shares of stock. The company has a paid-in capital of $500,000, which, according to the bill, has been expended in procuring patents and manufacturing machinery for the production of heat by electricity. The company has assets of $4,127, and liabilities of $10,908.

Massachusetts Street Railways.

The street railways of Massachusetts had, as shown by the annual report of the railroad commissioners, a very disastrous year in 1904. The report shows a deficit after the payment of all charges and dividends amounting to $216,383, as compared with a surplus of $16,668 in 1903 and $250,140 in 1902. The deficit is said to be primarily due to over-promotion.

The Schwerdtle Stamp Company.

The engraving and steel stamp business of the Schwerdtle Stamp Company, 39 Fairfield avenue, Bridgeport, Conn., and the rubber stamp business of the Bridgeport Stamp Company, 156 Fairfield avenue, have been incorporated under the laws of the State of Connecticut, and will hereafter be known as the Schwerdtle Stamp Company. The new company receives all the assets and assumes all the contracts and obligations of both old firms, and has opened for business in its new building, 39 and 41 Cannon street. The new factory has been equipped with increased facilities, including modern machinery, new type, etc., and will be able to handle increasing business more promptly and satisfactorily than ever before.

Prof. W. S. Barstow will deliver a lecture on the "Electrical Plant," at the Brooklyn Polytechnic January 23.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED JAN. 10, 1905

Electric Railways and Appliances.

779,441. Trolley Device. Henry O. Reese and Henry C. Weitzel, Baltimore, Md. Filed June 10, 1904.

779,448. Life-Guard for Electric Tram-Cars or Other Road Vehicles. William A. Turner, Marple and George A. W. Turner, Stockport, Eng. Filed Oct. 7, 1904.

779,475. System of Electrical Distribution for Electric Railways. Josef H. Hallberg, Cincinnati, O. Filed Feb. 26, 1904.

779,554. Trolley-Bridge. Robert T. McCarroll, Columbus, O., assignor to the Columbus Steel Rolling Shutter Company. Filed June 4, 1904.

779,654. Trolley-Retriever. Emil J. Jonas, Hamlet, O., assignor of one-fourth to Philip M. Offutt same place. Filed April 1, 1904.

779,739. Protective Device for Third Rails. John Ryan and Anthony C. Guntzer, New York City. Filed Nov. 5, 1903.

779,850. Trolley for Electric Railways. George C. Hobein, Norfolk, Va. Filed Sept. 17, 1904.

779,895. Signaling Circuit for Railways. Adoniram J. Wilson, Westfield, N. J., assignor to the Hall Signal Company, New York City.. Filed Feb. 10, 1902.

779,920. Track-Switch for Electric Railways. George H. Fretts, Springfield, Mass. Filed March 25, 1903.

Electric Lights and Appliances.

779,539. Electric-Arc Lamp. Walter C. Fish, Lynn, Mass., assignor to the General Electric Company. Filed June 24, 1901.

779.779. Electric-Lamp Fixture. Edwin E. Hayward, Waterbury, Conn., assignor to the Plume & Atwood Manufacturing Company, same place. Filed June 8, 1904.

779.948. Electric-Arc Lamp. Heinrich Lux, Schoneberg, Germany, assignor to the Allgemeine Belauchtungs und Heiz Industrie Actien Gesellschaft, Berlin, Germany. Filed June 8, 1904.

Electrical Machinery and Apparatus.

779,427. Electromagnetic Metal-Working Machine. Francis W. Jessop, Cleveland, O. Filed March 30, 1904.

779,447. Electric Controller. August Sundh, Yonkers, N. Y., assignor to the Sundh Electric Company. Filed June 3, 1904.

779,469. Coupling for Electric Cables. John J. Dossert, New York City, assignor, by direct and mesne assignments, to Dossert & Co. Filed July 16, 1903.

779,532. Connection-Board for Dynamo-Electric Machines. John G. Crawford, Lagrange, Ill., assignor to the Western Electric Company. Filed May 13, 1904.

779,575. Polyphase Winding. Bernard A. Behrend, Norwood, O., assignor to the Bullock Electric Manufacturing Company. Filed Nov. 6, 1903.

779,685. Current-Meter. Warren S. Blauvelt, Grosse Ile, Mich. Filed March 9, 1904.

779,720. Voltage-Regulator. Orra M. Lacey, Hanford, Cal. Filed Nov. 9, 1903.

779,737. Shunt for Electrical Measuring Instruments. Lewis T. Robinson, Schenectady, N. Y., assignor to the General Electric Company. Filed Aug. 18, 1904.

779,822. Bearing for Electric Meters. Frederick M. Vogel, Lynn, Mass., assignor to the General Electric Company. Filed July 13, 1903.

779,828. Insulator-Pin. Montraville M. Wood, Schenectady, N. Y., assignor to the General Electric Company. Filed Aug. 8, 1903.

779,875. Automatic Motor-Starting Rheostat. Ernest Schattner and Caryl D. Haskins, Schenectady, N. Y., assignors to the General Electric Company. Filed May 13, 1904.

779,889. Reversible-Current Apparatus for Condensers. John Todd, Seattle, Wash., assignor of one-half to George Winfield Wilson, same place. Filed March 14, 1904.

Telephones and Telephone Apparatus.

779,443. Telegraph and Telephone Transmission Line. Eugene F. Roeber, Philadelphia, Pa. Filed March 9 1901.

779,497. Apparatus for Telephone Trunk-Lines. Walter O. Pennell, Philadelphia, Pa., assignor to the Western Electric Company. Filed Nov. 23, 1900.

779,504. Telephone-Bracket. Samuel J. Seifried, Chicago, Ill., assignor to the Chicago Writing Machine Company. Filed Sept. 25, 1903.

779,533. Party-Line Telephone System. Willam W. Dean, Chicago, Ill., assignor to the Kellogg Switchboard & Supply Company. Filed June 15, 1903.

779,811. Selective Party-Line Telephone System. Albert J. Springborn, Cleveland, O. Filed April 3, 1903

779,893. Selective Signaling System. William D. Watkins, San Jose, Cal., assignor to the Watkins Manufacturing Company, same place. Filed Nov. 4, 1903.

779,940. Support for Telephone-Receivers. Frank F. Howe, Marietta, O. Filed Sept. 23, 1904.

779 982. Selective Telephone System. Peter J. Albrecht, Marion, S. D. Filed July 25, 1904.

Miscellaneous.

779,432. Polyphase Magnet. David L. Lindquist, Yonkers, N. Y., assignor to the Sundh Electric Company. Filed May 23, 1904.

779.508. Art of Electrical Wave Transmission. Daniel M. Therrell, Atlanta, Ga. Filed Feb. 17, 1902.

779,524. Printing-Telegraph System. John Burry, Ridgefield Park, N. J. Filed April 9, 1904.

779,553. Protective Covering for Storage Battery Plates. Achille Meygret, Paris, France. Filed April 6, 1904.

779,589. Electric Battery. Frederic P. Dewey, Washington, D. C. Filed March 25, 1902. Renewed May 19, 1904.

779,592. Signal System for Elevators. Bartholomew J. Foley, Pittsburg, Pa. Filed March 12, 1900.

779,623. Electric Pump. Edwin F. Porter, Boston, Mass., assignor, by mesne assignments, to the Porter Air Compressor Company. Filed Feb. 9, 1903.

779,670. Telegraph System. Harry Shoemaker, Philadelphia, Pa., assignor of one-half to Marie V. Gehring, same place. Filed Oct. 11, 1902.

779,673. High-Frequency Induction Apparatus. Chas. L. Spaulding and Robert E. Austin, Kansas City, Mo., assignors of one-third to William R. Clarke, same place. Filed April 25, 1904.

779.693. Battery-Zinc. Frank J. Delavie, Pittsburg, Pa. Filed July 1, 1904.

779,733. Electrode. Edgar F. Price, Niagara Falls, N. Y., assignor to the Union Carbide Company. Filed June 28, 1904.

779,735. Electrolysis. Giovanni Rambaldini, Minfera di Boccheggiano, Italy. Filed Jan. 28, 1902.

779,810. Electric Branding Apparatus. David C. Sprecher, Kansas City, Kan., assignor of one-half to John E. Doran, Kansas City, Mo. Filed Nov. 15, 1904.

779,844. Electric Furnace. David R. S. Galbraith, Auckland, New Zealand, assignor of one-half to William Steuart, same place. Filed Oct. 27, 1903.

779,996. Inductance-Coil. Walter C. Fish, Lynn, Mass. Original application filed June 24, 1901. Divided and this application filed Sept. 3, 1903.

THE TELEPHONE WORLD.

Independent Securities Company Obtains Many Lines.

An important deal has lately been consummated whereby the Independent Telephone Securities Company of Utica, N Y., secures control of the property of the Black River Telephone Company, whose lines extend from Utica north along the line of the Rome, Watertown & Ogdensburg Railroad to Sacket Harbor and Watertown, and from there through to Adams and Pulaski, and at the latter point working in conjunction with the Ontario Telephone Company of Oswego, whose lines also extend to Syracuse.

The Black River Telephone Company has exchanges in 22 villages, and operates over 1,000 telephones; has over 500 miles of toll lines in the northern part of Oneida, Lewis, Jefferson and Oswego Counties, nearly all of the lines being full metallic circuits and fully half of them of copper.

It is understood that both the Independent and Bell interests have for some time past been negotiating for the Black River line.

The Independent telephone exchanges in Cooperstown and Richfield Springs, together with the rural lines of the Otsego Home Telephone Company in and about Cooperstown, have passed into the hands of the Independent Securities Company of Buffalo, a branch of the syndicate now controlling the local companies in Rochester, Syracuse and Utica. The Cooperstown exchange has about 250 'phones and the Richfield Springs exchange about the same number. In the towns about Cooperstown there are some 200 'phones of the Otsego Home Company. and these will be connected with the exchange at the county seat and given service from that point. The consolidation of these companies is a part of a general plan to combine for more effectually competing with the Bell Company.

The David City, Neb., telephone exchange recently passed into the hands of the Surprise Telephone Company. The exchange was built several years ago by F. C. Scott and conducted as an Independent exchange exclusively until about four years ago, when arrangements were made and it was connected with the Nebraska Telephone Company. The Surprise Company has since the first of this year, purchased the exchange of the Independent Telephone Company at Brainard. J. E. Keebaugh, formerly of Surprise, succeeds Mr. Scott as general manager of the telephone business in David City.

The new telephone system of the St. Louis County, Mo., Telephone Company, an Independent organization, has started in to cut rates and furnishes a 'phone in residences for $1.50 a month, and in business houses for $2 a month. While this system was built primarily to afford local communication, arrangements have been made whereby St. Louis connection can be secured by the payment of toll rates to the other lines. The 'phones work automatically, dispensing with the services of an operator.

Work on the new telephone line from Huntsville to Jeff, Ala., was recently commenced. D. E. Kelley, owner of the new line, promises a most excellent service to the people along the route.

Telephone Competition in Alabama.

The city council of Tuscumbia. Ala., has granted a 25-year franchise to John C. Montieth and associates of Chicago for the construction and operation of a telephone line throughout that city. It is the purpose of the gentlemen securing the franchise to erect an Independent long-distance line and also an Independent local line in competition with the Southern Bell, which has enjoyed an open field for several years in Tuscumbia, Sheffield and Florence.

Telephone System Reincorporated.

The South McAlester-Eufaula telephone system was lately reincorporated at South McAlester, I. T., with the following officers: William Busby, president; C. E. Foley, vice-president; L. H. Roberts, secretary; D. M. Hailey, treasurer. The company owns several hundred miles of telephone lines in Indian Territory, and will expend $50,000 in improvements, installing the central agency system instead of the present old-style system.

The directors of the Churchville, N. Y., Telephone Company have elected the following officers: President, W. L. Ormrode; vice-president, C. H. Briscoe; secretary, C. G. Stewart; treasurer, F. W. Potter. By general consent, an assessment of 20 per cent. has been levied on the capital stock. Two committees have been appointed, one on contract and right of way, and the other on construction. A special agreement was made that no shares should be sold except subject to the approval of a majority of shareholders. This proviso is a safeguard against any company or concern acquiring a controlling interest to the detriment of the company In matters of business in the regular board meetings each share of $100 is entitled to a vote.

The Glen Telephone Company has notified its subscribers in Gloversville, N. Y., and vicinity, that on February 1 the rates for local service are to be increased. It is said that the proposed increase causes a large amount of dissatisfaction among the subscribers, and that an effort will be made to force the company to rescind its action. The common council may be asked to take action in the matter, as it is believed that under the company's franchise it has no right to increase the charges. Officials of the company state that it is necessary to make the increase for the welfare of the business, as under the old rates there was no profit in the enterprise.

The Rich Hill, Mo., city council lately held a special session to receive a proposition from S. J. McComb, of Humansville, Mo., who proposed to put in a local telephone system, cable the wires, give the city 2 per cent. of the gross receipts and free municipal 'phones, providing a 20-year franchise is granted.

The Western Telephone Company of Big Springs, Tex., has filed an amendment to its charter increasing its capital stock from $15,000 to $30,000.

The Little Kanawha Telephone Company of Grantsville, W. Va., wants prices on electrical supplies.

Wayne Telephone Companies Unite.

The Wayne County Telephone and the Wayne-Monroe Telephone Companies have united. While there has been no merger or consolidation of the two companies, and while separate boards of officers and directors were elected and separate stock issues made arrangements have just been perfected whereby greatly to the mutual benefit of patrons and directors of both corporations, the two companies are now connected. The Wayne Telephone Company has existed in Lyons and the adjoining towns for some years. The lines of the Wayne-Monroe Company extended throughout the northern and western towns of the county and between the two there was no connection.

By the establishment of the union of the two lines, a telephone service from one end of Wayne County to the other. and with stations in Buffalo, Oswego, Syracuse, Binghamton and intermediate places is now in operation. These increased telephone facilities are bringing about the installation of hundreds of new 'phones throughout the county. In Lyons alone rush orders for telephones are going in daily, while throughout the county 1,100 machines have been established. In addition to the advantage of an entire Wayne County service and a greatly increased service throughout the State, the price of telephones per year has lowered and toll rates to any outlying district of a town are now given with the price of the 'phone. County Clerk Ledyard C. Cuyler and Sheriff Albert Yeomans are with others interested in the union of the two companies. of which John A. Driscoll is the general manager.

New Telephone Line for Missouri.

St. Joseph and Cameron, Mo., are now connected by three telephone lines. The Funston Long Distance Telephone Company lately opened the third line, and its wires are connected to the Central office of the Citizens' Telephone Company. The line is 40 miles in length. It follows the right-of-way of the Burlington to Cameron. About 1,500 subscribers, including the Cameron exchange, will be accommodated. Among the towns reached by the company are Stewartsville, Osborn, Hemple and Saxton. J. G. Funston, superintendent of the Citizens' Telephone Company, is secretary and general manager of the Funston Company. E. B. Funston of Racine, Wis., is the president.

The Dodge City Telephone Company is extending its line to Ford City and thence to Bucklin on the Rock Island, and with the line owned by the farmers in the southern part of the county it forms a network of lines covering nearly the whole of the southwest part of Kansas.

At the annual meeting of the Bergen, N. Y., Telephone Company the following officers were elected: President, G. M. Gillette; vice-president, J. S. Gleason; secretary, Holden Miller; treasurer, C. E. Housel.

W. H. Burke, of Clifton Springs, N. Y., and W. C. Ellis, of Shortsville, who have been interested in several telephone companies operating in Ontario County, have sold their interests to the Long-Distance Inter-Ocean Telephone Company of Buffalo.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Albuquerque, N. M.--A franchise has been granted to Joseph Barnett to build and operate an electric light plant in the city limits.

Appleton City, Mo.—The city officials are negotiating for a franchise with S. J. Culbertson, of Vandalia, whereby this city may have electric lights.

Arcanum, O.--A petition has been presented to the council asking for a vote of the people on issuing $35,000 in bonds for the construction of a waterworks and electric light plant.

Barberton, O.—A new electric lighting plant may be installed here.

Boyd, Wis.—The Cadott Electric Light & Power Company of this city is seeking a franchise.

Canadian, Tex.—The installation of waterworks and an electric light plant is being discussed. J. F. Johnson is chairman of the committee.

Frankfort, Ky.—The People's Electric Company has a contract to furnish the city with electric lights.

Freehold, N. J.—The Freehold electric light plant was recently sold with its franchises to P. A. V. Van Doren, of Princeton.

Georgetown, Ill.—A franchise for an electric lighting plant has been granted to John Searl, of Chicago. Work will soon be commenced.

Gorin, Mo.—J. K. Schackett and D. A. Frazee have been granted a 20-year franchise to erect an electric lighting plant here.

Hartford, Ky.--It is reported that J. W. Hale, of Fordsville, will build an electric light plant.

Jefferson City, Tenn.--The Jefferson City electric light plant was recently destroyed by fire. The loss is estimated at $4,000.

Kingman, Kan.—A petition will soon be presented to the city council asking that a franchise be granted to W. S. Grosvenor, giving him the right to establish and operate an electric lighting plant here.

La Crosse, Wis.—Dr. E. C. Swartout has filed an application for a franchise to furnish electric current and power in this city. This is the second application for a lighting franchise in a month to compete against the La Crosse Gas & Electric Company.

Lake Charles, La.—The city council has under consideration plans for the erection of an electric light plant, to cost about $60,000.

Marksville, La.—The question of levying a 5-mill tax for 20 years, for the purpose of installing a system of waterworks and electric lighting plant here was carried at the recent election.

Milwaukee, Wis.—The Milwaukee Electric Railway & Light Company's plant was lately destroyed by fire entailing a loss of $5,000.

Montgomery, Minn.—The Montgomery Electric Light & Power Company will be formed by S. A. Vopatek, and a plant installed at once.

Morrill, Kan.—A citizens' committee has under consideration a proposition to establish an electric light plant here.

Palmyra, N. Y.—The Palmyra Electric Light & Power Company has been sold to William J. Morris, of Penn Yan, who will immediately improve and repair the same.

Perth Amboy, N. J.—Alleging that the Public Service Corporation is unduly discriminating against this city, a number of local merchants are planning to form an independent electric light company and manufacture current for their own use. Some of those interested in the movement are Peter Floersch, Kelly & McAlinden, Sickles Brothers, Gannon & Sheehy, F. W Woolworth & Co., L. Briggs and S. M. Jacobsen.

Pitman Grove, N. J.—M. K. Treichler, of Philadelphia, Pa., who recently purchased the electric light plant here, proposes to improve and extend it.

Poplar Bluff, Mo.--W. B. Hays, W. H. Wiisey and D. P. Bacon have acquired the electric light plant and will make improvements.

Renton, Wash.—The Seattle Electric Company is planning to ask the city officials of Renton for a franchise to construct a branch of its system to this place, and furnish electricity at the rate of $1 for each light put in.

South Boston, Va.—The South Boston Electric Light & Power Company contemplates making extensive improvements to its plant, increasing the capacity, etc.

Sumter, S. C.—J. L. Alnut represents parties who propose building an electric light plant here. He has petitioned for a franchise.

Terre Haute, Ind.—The council has authorized the employment of expert electricians to assist in the investigation of the feasibility of establishing a municipal plant.

Uvalde, Tex.--This city is to have an electric light plant.--A franchise has been granted and the plant will be erected soon.

Waterloo, Ia.--The Waterloo & Cedar Falls Gas & Electric Light Company has been incorporated with a capital of $595,000, by Frank J. Fowler and others.

STREET RAILWAYS.

Akron, O.—The Northern Ohio Traction & Light Company will erect a line from this city to Cleveland and Canton.

Anderson, Ind.—Wallace B. Campbell, of this city, who is promoting an electric railway between here and Lebanon, by way of Noblesville, says that he has begun negotiations with a Chicago corporation that agrees to finance the road if satisfied with the results of an investigation.

Boise, Idaho.—Arrangements are being made for the erection of a trolley line to South Boise aross the Broadway Bridge.

Erie, Pa.—A trolley line will be erected connecting Cambridge Springs, this city and Pittsburg.

Elyria, O.—The Cleveland & Southwestern Traction Company's car barns were destroyed by fire. Loss is estimated at $20,000.

Grafton, W. Va.—The Grafton Railway & Light Company, with a capital of $400,000, has been incorporated by W. E. Horton, George W. Powell and others, to construct an electric railway and an electric light and power plant here.

Indianapolis, Ind.—Articles of incorporation have been filed at the office of the Secretary of State for the Central Electric Traction Company of Indiana, capitalized at $25,000.

Missoula, Mont.—The Amador Railway Company has been incorporated with a capital of $1,000,000. The system is to be electric.

St. Louis, Mo.—Local property owners are planning a new electric line to run north of this city and Ferguson.

Webb City, Mo.—H. M. Baker, of Carthage, has begun working to secure the right of way for the building of an electric line which is proposed. to be built from here to Oronogo, Alba, Neck and terminating at Carthage.

POWER PLANTS.

Muskogee, I. T.—It is reported that the Commercial Club contemplates developing the power of the Grand River, 10 miles from this city, and has engaged engineers to make surveys for the location of a power house.

Omaha, Neb.—The Baxter Springs Electric Power Company of this city, has been incorporated with a capital of $30,000 by E. T. McCarthy, R. W. Bailey and others, to operate an electric power plant.

Pittsfield, Mass.—The Pittsfield Street Railroad Company is considering a site for a new power plant, which it will build at once.

Rockingham, N. C.—Hugh MacRae & Co., of Wilmington, N. C., has purchased the Bluett Falls water power property on the Pee Dee River near this city. The company proposes forming a corporation to develop the water power, and build an electric light plant for transmitting electrical power to industrial enterprises within a radius of 20 or 30 miles. It is reported that 30,000 hp. can be obtained.

BIDS WANTED.

Camden, Ark.—The Camden Light & Power Company is in the market for two dynamos, one boiler, engine transformers and arc lamps.

Canadian, Tex.—The Canadian Gin & Milling Company wants prices on equipment for an electric light plant.

Columbia, S. C.—Engineer C. C. Wilson, of this city, will receive bids until February 15, for the construction of an electric light plant for Clinton, to cost $25,000.

Cropley, Md.—R. Scott Allen, of this place, is in the market for a new or second-hand 25 to 30 hp. engine.

Dallas, Ga.—The Dallas Light & Power Company wants to purchase a good second-hand 50 or 72-inch return tubular boiler.

Fort Snelling, Minn.—Bids will be received until January 21 at the office of R. N. Schofield, constructing quartermaster, St. Paul, for the construction of an addition to the electric system here.

Walla Walla, Wash.—Sealed bids will be received in triplicate until January 31 at the office of the constructing quartermaster in this city for installing interior conduit and wiring for electric lighting of two double barracks at Fort Walla Walla. Address Noble H. Creager, captain and quartermaster United States Army.

Washington, D. C.—The Department of the Interior will receive bids until January 24 for the construction of extensions to the water, sewer and electric lighting systems at the Riverside School, Cal.

Wilmington, N. C.—The Southern Electrical Company of this city is in the market for all kinds of electrical supplies.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 15⅜@15½c.; Lake 15½@15⅝c.; casting, 15¼@15⅜c.

Electric Storage Battery was strong in Philadelphia on Monday, advancing 1½ points.

Copper prices were advanced ⅛ cent per pound all along the line on Monday.

The stockholders of the Brooklyn Rapid Transit Company will hold their annual meeting on January 27.

Interborough Rapid Transit stock made a gain of 20 points in this city last week. The stock is on a 6 per cent. basis.

J. P. Morgan & Co. will act as managers of the $36,000,000 syndicate formed to reorganize the Chicago traction companies.

The preferred and common shares of the Boston & Worcester Electric Companies have been listed on the Boston Stock Exchange.

A dispatch from Newark, N. J., says that the Interborough Company is about to take over the trolley system of the Public Service Corporation.

The directors of the Edison Electric Illuminating Company of Boston have declared a regular quarterly dividend of 2½ per cent., payable February 1.

The American Graphophone Company has declared the regular quarterly dividend of 1⅜ per cent. on its preferred stock, payable February 15 to holders of record February 1.

The Metropolitan Street Railway Company of Kansas City carried 40,000,000 people the past year and its gross receipts were close upon $2,000,000. Its net income was a little over half this amount.

A pool has been made in Cleveland of the remaining assets of the Everett-Moore syndicate. The bankers' committee, controlling them, it is stated, will completely satisfy all remaining creditors.

A loan of $10,000,000 to the Philadelphia Rapid Transit Company is being negotiated, the money to be used to complete the Market street subway in that city. It is said that Drexel & Co. will probably take the loan.

At a recent meeting in Philadelphia of the directors of the Electric Company of America they increased the semi-annual dividend on the stock of the company to 3½ per cent. from 3 per cent., thus putting the issue on a 7 per cent. basis.

The directors of the Marquette County Telephone Company of Ishpeming, Mich., have declared an annual dividend of 10 per cent. The company is an independent concern, composed of local men, and gives the Bell people stiff competition.

There was marked strength in the electric issues on the New York Stock Exchange Monday. General Electric advanced 2⅛ points and Westinghouse went up 3½ points. Several thousand shares of each were traded in, but there was no news to account for the rise.

John J. Mitchell, president of the Illinois Trust & Savings Bank, has made the first official statement as to what the new Morgan-Field-Mitchell traction syndicate is prepared to accomplish. As spokesman for the syndicate he asserted that $36,000,000 had been raised to control the Chicago City Railway Company. "Negotiations will be taken up with the city for renewal of the franchise on the basis of one company, one fare," he said. "When an agreement is reached the companies under the control of the syndicate will be merged to carry out the provisions of the ordinance."

ELECTRICITY.

VOL. XXVIII. NEW YORK, JANUARY 25, 1905. NO. 4.

ELECTRICITY.

Published every Wednesday by the
ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.
Long Distance Telephone, 4021 Cortlandt

SUBSCRIPTION RATES:
United States, Canada and Mexico..$1.00
Foreign Countries.................... 3.00
Single Copies....................10 cents
Remit by Draft, Post Office Order, Registered Letter or in Stamps.

Owing to the expense involved in keeping back numbers, papers over two years old will be charged for at the rate of 25 cents apiece.

ADVERTISING RATES.

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than Saturday morning preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

EDITORIAL NOTES.

Rapid Transit in Brooklyn. Rapid transit in Brooklyn does not mean the Brooklyn Rapid Transit Company. Why conditions in the sister city to New York should have been allowed to fall into such a deplorable state can be best explained by the general apathy, or—to use a better expression—resignation, into which the other half of Greater New York has fallen in the last decade.

The stimulation given to public interest by the opening of New York's Subway has forced the board of directors of the Rapid Transit Company to the conclusion that the rehabilitation of the plant, which may mean an expenditure of $20,000,000, is the only way out of a problem bristling with difficulties. Brooklyn is New York to-day—although when the surface and elevated systems were first projected it represented a distinct municipality. Since that time the traction system has been patched and extended and brought into New York over the bridge. Glaring defects became evident when the rush hours began, and Brooklyn people found out that the years of their lives were too precious to be spent traveling in overcrowded, underheated, snail-like "trolleys." Public condemnation is like a blast from Gabriel's trumpet to the sluggish ambitions of heavy stockholders. It gains weight and force and threatens the very life of corporate interests. This has been the case with the street railway company of Brooklyn. It is now about to initiate changes which, it is anticipated, will transform the character of the outcry from criticism to commendation. In the meantime the subway is being pushed to Brooklyn through tunnels under the East River and New York Bay.

With a $20,000,000 expenditure about to be made to improve the surface system, and a subway rapidly nearing its completion, the people of Brooklyn may soon find more comfort in traveling in their own city than we in this over-congested borough on the other side.

* * *

The Telephone Monopoly. Elsewhere in this issue will be found an excellent account of the Telephone Trust's history in this city. Almost every year there is talk of "exorbitant rates," how "the Legislature will enact a law controlling rates," how the "people are being robbed," etc., etc., and yet nothing has been accomplished. The "Herald," which is now fighting the Telephone Trust, states that facts and figures are to be laid before the Legislature which the advocates of relief from the exactions of the telephone monopoly in New York City hope will compel action by the lawmaking body of the State. The paper further says that investigation is now being made by one of the foremost experts in the country, and that the discoveries so far made are of a character to make telephone reform almost inevitable, unless influences are brought to bear to prevent it.

For the past 10 years or more these influences that the "Herald" speaks about have annually been brought to bear, and the chances are that they will again be sought for. It should be borne in mind that in seeking more just and equitable telephone rates for this city, that both political parties have to be reckoned with and the New York Telephone Company is very friendly, and has been for years, with both parties and especially with the Republican organization, which usually controls the Legislature. As a result all of the bills looking to cheaper telephone rates that have been introduced at Albany, have invariably been "laid on the table,' and lost or buried in a pigeon hole. Let us hope the bills this year will not share a like fate.

* * *

The Safety of Electric Plants. By some peculiar means of reasoning the tradition gained ground that electricity is a dangerous thing to meddle with, and the public satisfied for a time, as many are to-day, with the truth of this proposition, gazed with apprehension upon the rapid developments taking place in this sphere of activity. The electrician was and is regarded as a wizard, with a certain mysterious power of control over elusive forces, and this idea, perhaps, aided by the statements and sensational experiments of charlatans, has led to a belief, more firmly founded in the old than the new generation, that electricity only represents shocks, burns, death and fire. The exact manner in which it may be used for electric lighting, for the operation of motors, or the running of electric car systems has not as yet found its way into the layman's mind. Neither an abstract nor a concrete idea exists there in this respect. That which happens is unfortunately accepted as it stands, and an active interest is only manifested when, to use a popular expression, the car or lights cease to operate because "a fuse blows." It is hard for the great mass of bread winners to realize that their personal safety is greater in a building lit by electricity than one lit by gas; that an electric car is by far a safer, healthier and better controlled vehicle than one operated by steam or any other fluid. And finally, aside from other considerations, the risks from fire belong to such a category, that the insurance people believe a building wired with up-to-date methods is the best risk on their books. This, of course, leads us to a consideration of the electric plant as a whole. What degree of safety can be guaranteed in connection with it? What part of such an equipment can be regarded as the most susceptible to the influence of destructive changes? The natural and logical answer to the last would be the boiler, and to the first a correct answer would be framed in these words:

The degree of safety that can be guaranteed in connection with an electric plant consisting of boiler, engine, dynamo and wiring is largely dependent upon the care of the boiler and engine. It rarely happens that well installed wiring, "iron conduit" as it is called, gives or can give any trouble. The risks of fire here are at their lowest possible figures. The dynamo is similarly not susceptible to change unless it is heavily overloaded or neglected as regards oiling, etc. A well made engine represents more risks in this respect, although in the hands of a careful man they also are reduced to a minimum. What is left and is acknowledged as the greatest source of danger is the boiler. The boiler inspecting and testing commission, to a large extent, have this responsibility on their hands, yet the engineer must see that the boiler is kept clean and the safety valve is always operative at the set pressure. These facts remove all doubt as to the safety of electric plants, particularly the electrical part, and show that a well-paid, well-trained and intelligent engineer is the only one fit to discharge the duties required of him. In such hands the safety of electric plants is assured and it would be almost epigrammatic to state that "the safeness of electric plants is the safeness of those in charge of them."

Chicago's fourth annual automobile show will be held from February 4 to 11.

◆

The City Council of Cleveland, O., has authorized the Cleveland Electric Railway Company to begin an experimental service to determine the profitableness of a three-cent fare within a radius of two miles from the center of the city. No transfers will be given on the three-cent cars. The street car company has the right to abandon the experiment at its discretion.

◆

Opposing the opinion of Dean Hutton, of Columbia College, New York, who said that some of the students had "really stolen their degrees," Prof. George F. Sever, of the department of electrical engineering at the university, has given it as his testimony that the "outside talk about the honesty of Columbia students is false." Prof. Sever, in speaking to one of his classes, said: "Absolutely no unfair means are employed by the students in the school of applied science. The students should resent such attacks as are aimed against Columbia. Honesty at Columbia is at a higher standard than at most other universities."

◆

The 193d meeting of the American Institute of Electrical Engineers will be held at the Chapter Room, Carnegie Hall, 154 West 57th street, New York, on Friday, January 27, at 8:15 P.M. The subject selected for this meeting is "Central Stations." The following papers will be presented and discussed: "Acyclic (Homopolar) Dynamos," by J. E. Noeggerath; "Modern Central Station Design as Exemplified by the New Turbo-Generator Station by the Edison Electric Illuminating Company, of Boston," by I. E. Moulthrop.

◆

The National Electric Light Association at its last meeting in Boston changed the by-laws so as to admit as individual members professors of engineering, chemistry and physics. Mr. Henry L. Doherty, chairman of the committee on membership of the association, is now inviting these educators to join the association and requests members to send him the names and addresses of such instructors.

◆

Electrical Inspector H. J. Blakeslee of the Hartford (Conn.) Board of Fire Underwriters in his annual report says that the increase in the use of electricity in Hartford during the last few years has been 54 per cent. Out of 231 fires in Hartford in 1904, only 6 were electrical, and the average for three years was only 1.9 per cent. Many of the fires were caused by the carelessness of gas plumbers in handling and tampering with electric lighting circuits they came across in their work.

◆

The New York "Times" says "there seems to be some sort of a spell upon the municipal ownership people that prevents them from so keeping their books as to show the exact financial results of their operation. This is not less to be lamented by those who hope to find in such ownership of public utilities a remedy for many existing evils than by the antagonists of the hopeful ones, who think the plan dangerous and chimerical."

NEW YORK CITY TELEPHONE HISTORY.

(From the New York Herald).

Hitherto sincere efforts to invade the metropolitan field of the Bell telephone monopoly have invariably met with disaster. Men who were so presumptuous as to embark in such an enterprise have usually discovered that the Telephone Trust has a long arm, a crushing grip and that it can mould men and things to its will.

Many competitive schemes have been exploited in New York City within a decade. Time and again the newspapers have told of the incorporation of this company or that which purposed an immediate attack upon the Trust in its metropolitan stronghold. Promoters of such companies have given out rosy prospectuses, predicting the cutting in half of telephone rates in New York. Some of these enterprises were undoubtedly genuine, and their backers attested the sincerity of their motives by losing thousands of dollars before they finally yielded. Others were organized with little better purpose than to sell out at profitable terms to the monopoly. Those that lacked the elements of formidable competition the Telephone Trust has discreetly ignored. The few that developed dangerous strength the Trust either has crushed or crippled by some of the many insidious methods in which the Bell monopolists are experts, or else, if its franchises and other assets were really valuable, the Trust has usually managed adroitly to acquire them or so to dominate them as to make them subservient to the purposes of undisputed monopoly.

We will undertake to sketch briefly the rise and fall of one of the most ambitious of these competitive enterprises, the Telephone, Telegraph & Cable Company of America. That corporation, beset by litigation, with its once aspiring capitalization of $30,000,000 shrunk to $9,000,000, maintains at least a nominal corporate existence, with an office at No. 100 Broadway. But it is innocuous so far as the Bell monopoly is concerned and the Trust regards its present situation with complacency.

Its president to-day is Henry S. Kearny who was Mayor Van Wyck's Commissioner of Public Buildings, Lighting and Supplies, who has maintained close and friendly relations not only with Tammany but also with the Bell telephone interests, who when a commissioner and in control of the city's underground electrical conduits was questioned before the Mazet Investigating Committee concerning the difficulties experienced by independent companies in getting permits to utilize those conduits, and who since becoming the official head of the Telephone, Telegraph & Cable Company of America has refused to deny the published and generally accepted statement that that unhappy corporation is now wholly in the toils of the Bell Telephone Trust.

One of the competitive enterprises which doubtless had genuine, serious intentions of invading the New York City field several years ago, was the old Knickerbocker Telephone Company, which was organized as an operating company to do business in New York City. It had behind it substantial interests and its general manager and afterward its president, Gen. William H. Eckert, brother of Thomas T. Eckert, of the Western Union Telegraph Company, worked hard for its success for many years, though without any marked degree of substantial public support. The Knickerbocker Company, however, had acquired franchises and privileges, which made it a factor to be reckoned with.

Its permit to use the Manhattan electrical undergound conduits had been granted seemingly with little difficulty in the official incumbency of Commissioner Kearny, and that, too, at almost the identical time when Mr. Kearny was being hauled over the hot coals of the Mazet investigation by Frank Moss and the present Judge Clarke, who were counsel for that legislative committee. They wanted to know why it seemed to be impossible to obtain a subway permit in behalf of the People's Telephone Corporaton, an independent company organized by Darwin R. James and other prominent members of the Board of Trade, which latter organization had been for years fighting the Telephone Trust in Albany for a reduction of its extortionate rates. When on the stand Commissioner Kearny excused the apparent holdup of the People's Company's permit by petulantly asserting that Mr. James' corporation was organized solely to sell out to the Trust, but the permit afterward was granted to the People's Company, as well as to the Knickerbocker.

In the meantime the Erie Telephone Company had been making marked headway in operating an independent telephone service, with valuable franchises, extending westward from Erie along the line of the great lakes, cutting into the Bell monopoly's profits at many important points, and the Boston & New York Telephone Company, with certain operative rights in Boston and elsewhere, was looming up as the possible independent factor, not only in a competitive system throughout New England, but also as the projected link in a competitive line between Boston and New York.

This was substantially the telephone situation when certain ambitious capitalists conceived the idea of incorporating the Telephone, Telegraph & Cable Company of America as a holding company to acquire the control of various independent operating companies. In November, 1899, with a capitalization of $30,000,000, divided into 600,000 shares of a par value of $50 each, the Telephone, Telegraph & Cable Company was incorporated in Trenton. The incorporators were William J. Latta, who for years had been general agent of the Pennsylvania Railroad Company, and who became the president of the new corporation; Martin Maloney, of Philadelphia, chief promoter of the enterprise, and commonly known in Philadelphia as a useful agent of the Whitney-Elkins-Widener interests, and James E. Hays, of Camden, N. J., who was said to be a legal representative of the same syndicate of capitalists.

It was announced with some ostentation that the power of the Whitney-Widener-Elkins combination was enlisted in the new enteprise, and that at last relief from Trust oppression was in sight. John E. Mack, of Philadelphia, wealthy, and president of the Keystone Telephone Company of that city, which was then and still is maintaining an independent service, came into the scheme, and many New York men, such as Frank Tilford and Henry R. Wilson, president of the Lincoln Trust Company, whose sincerity could not be doubted, took an active interest in the proposed coalition, and were afterward members of the board of directors.

For a time the affairs of the Telephone, Telegraph & Cable Company went swimmingly. The various operating companies with their rights and assets, were absorbed by the holding company and the new combination appeared distinctly formidable. But presently there appeared published denials of the assertion that the Whitney-Widener-Elkins-Ryan syndicate was the backbone of the concern. Martin Maloney, the promoter, remained conspicuously active, but it was announced that the wealthy capitalists with whom his name was usually associated, had found they had "other interests," which were not exactly in harmony with the interests of the Telephone, Telegraph & Cable Company, and that while they would not entirely hold aloof from the enterprise, their names should not be identified prominently with it. The affairs of the big competing corporation began to look less rosy.

Acquisition of the Knickerbocker, the Erie and the other operating companies considered essential to the enterprise had been costly. Assessments were called for from the subscribers to the stock of the holding company. Dissatisfaction was evident among many of them, and there was talk of mismanagement and the need of reorganization.

John E. Mack, of Philadelphia, who had paid in $100,000, and had subscribed to $500,000 of the stock, withdrew his support, and litigation involving those sums is still pending between Mr. Mack and the company.

William J. Latta remained the company's president until early in 1901, when he was succeeded by the late Judge James M. Thomas, of Cleveland, who was president of the Independent Telegraph System of America. The board of directors was reorganized and in April, 1901, the company reduced its stock capitalization to $9,000,000, by reducing the par value of the shares from $50 to $15 each.

With more or less friction and dissatisfaction, and with the prospect of further assessments upon the stockholders to meet necessary expenses, the company drifted along until midsummer. Then, at the psychological moment, a new and masterly figure came upon the stage and took his place in the limelight.

It was Charles W. Morse, the same Mr. Morse who had been the head and front of the American Ice Trust, the intimate personal and business friend of the high men of Tammany Hall, the buyer of banks by wholesale, including the New Amsterdam, the Garfield National and the National Bank of North America; the buyer of steamboats and of corporations, and just now the central figure, though personally in Europe, in the interesting imbroglio commonly known as the Morse-Dodge-Gelshenen mystery.

Mr. Morse, seeing another opportunity for a brilliant financial stroke, offered to buy outright the Telephone, Telegraph & Cable Company of America if a majority of the stockholders would consent to sell out at 50 cents on the dollar.

At this stage of affairs it was announced that some of the stockholders had not thus far made any payment on the second and third stock assessments, but the amount actually paid in aggregated about $4,000,000, so that Mr. Morse's offer of 50 cents on the dollar would involve cash payments by him in exchange for at least two-thirds of the stock of a sum ranging between $1,334,000 and $2,000,000.

Wearied and drained by assessments, the stockholders jumped at the offer. In the following September Mr. Morse found himself in absolute control of the Telephone, Telegraph & Cable Company of America. On October 14 the old board of directors retired and Mr. Morse substituted one headed by himself and consisting largely of either personal friends and business associates or officials of some of the various national banks in the chain of those institutions controlled by him. To some who were disposed to demur Mr. Morse asked that they serve as a personal favor to him, assuring them that their names were wanted "only temporarily."

Judge Thomas, who remained as president and who at that time was also president of the Knickerbocker Company, at the close of the meeting at which the new board was installed said hopefully:

"It is the intention of the Boston & New York Telephone Company, which is one of the constituent companies of the Telephone, Telegraph & Cable Company of America, to proceed vigorously with the completion of the line between New York and Boston. At the New York end we have completed the line as far as White Plains, while in Boston the work has proceeded to a satisfactory extent. It is impossible to tell just when the line will be finished between the two cities, but the work will proceed without delay. .

"As for the Knickerbocker Company, we fully expect to be in operation in the Borough of Manhattan within 12 months, but probably only in the lower part of the city, perhaps below 8th street. The system, however, will be rapidly extended. We shall operate through the Empire Company's subways and we intend to introduce many improvements in telephone service."

More that three years have elapsed since Judge Thomas made these predictions. He probably believed them when he made them and the public accepted them and hailed Mr. Morse as the pioneer of a new era in telephone competition. But these predictions have singularly failed of fulfillment. Judge Thomas retired as president and was succeeded by Henry S. Kearny, who still serves in that capacity, occupying in solitary grandeur and without evidence of clerical or other assistance an upper floor room at No. 100 Broadway, over the door of which appears the name "Telephone, Telegraph and Cable Company of America."

Mr. Morse's board of directors, headed by his own name, has also retired in a body. The present directorate consists, according to the Directory of Directors for 1904, of "Louis Baust, J. R. Burnett, James E. Hays, Henry S. Kearny, R. B. Kerr, Paul F. Lorzer, John E. McDonald and F. C. Purchase."

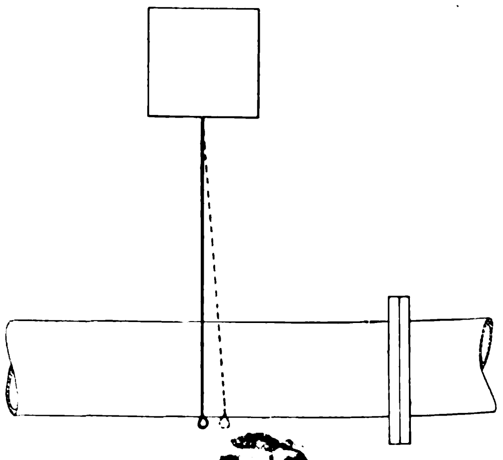
If the company has ever operated between New York and Boston since the advent of the Kearny regime New York has not heard of it. Its wires in Mount Vernon were torn down last winter. Before Mr. Morse went to Europe some of his acquaintances who thought his telephone purchase had been made at pretty stiff figures, said to him: "Morse, I hope that was not two millions of your own money you gave for the Telephone, Telegraph and Cable Company."

Mr. Morse smiled shrewdly and closed one eye ever so little, but he made no other reply. Since then the assertion has been made in print by a conservative evening newspaper that the Telephone, Telegraph and Cable Company of America has passed into the control of the Telephone Trust.

SUPPORTS FOR MAIN STEAM PIPES.

BY W. H. WAKEMAN.

Main steam pipes are frequently supported in such careless and indifferent ways that the subject calls for more attention on the part of those engaged in such work. If such pipes were always cold or hot, th[illegible]d be much more simple, b[illegible] cold, consequently are [illegible]ir shortest length. As steam is supplied their temperature arises and expansion increases their length, thus making the problem of their proper support much more complicated than it otherwise would be.



[illegible]

Fig. 1 illustrates a plan very commonly adopted for this purpose. It consists of welding a lag screw on one end of an iron rod and forming an eye on the other. Two of these are screwed into a floor timber and a rod is passed through the eyes, also through a rough iron roller on which the pipe rests.

The pipe is supposed to turn this roller as it increases in length, but it seldom does because the roller is too rough, while the supporting rods are not stiff enough to retain their original position. The full line in Fig. 1 shows the position of hanger when pipe is cold. If it was stiff enough to retain this position, no trouble would result; but as a rule a hanger of this kind is not, therefore it swings into the position shown by the dotted line, the effect of which is to raise the pipe slightly, thus throwing it out of line and bringing strain upon it unequally.

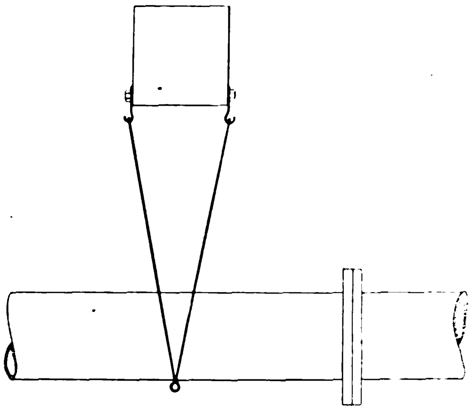


Fig. 2.

Fig. 2 shows a better arrangement, not only because a pair of hangers on each side are stronger than one, but each acts as a brace to prevent the swinging action illustrated already. This answers very well where the pipe is near the ceiling, but if it is a large pipe and is several feet from the floor timbers, Fig. 3 is better. This is not only very strong but is well braced, thus compelling the roller on which the pipe rests to turn as the metal expands.

Fig. 4 is a sectional view of a roller as frequently found in service. It is a rough casting just as it came from the foundry, therefore it does not turn easily, and when forced to turn it is higher in some positions than in others. If it was bored and turned until round inside and outside, it would operate much better, as it would turn easily and when it moved the pipe would not be thrown out of level. It is not expensive to machine these as described because they are cored out, as shown in Fig. 5, therefore only a small part of each requires boring. As these rollers bear on the ends only of the supporting rods, the latter are not sprung as much by the weight as they would be were the bearing at the center.

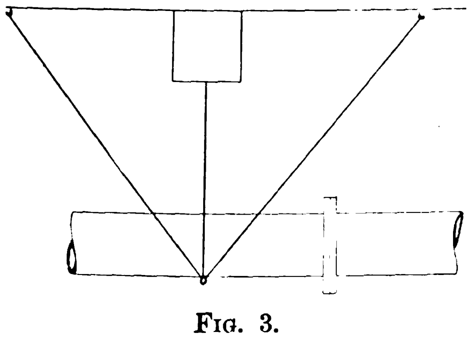

Fig. 3.

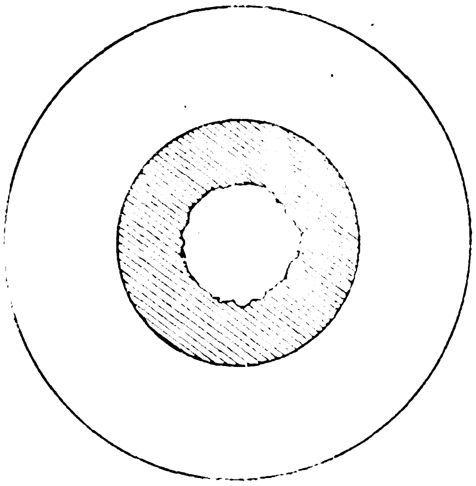

Fig. 4.

Fig. 6 is an end view of the pipes shown in previous illustrations. In some cases the pipe covering is carried up against the rollers, making it impossible for them to turn, even if all other conditions were right for free movement, which is a defect that should not be allowed.

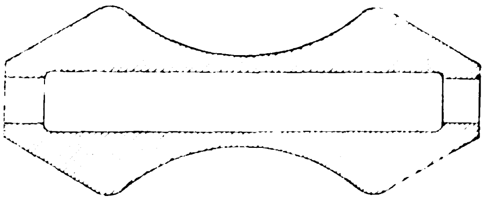

Fig. 5.

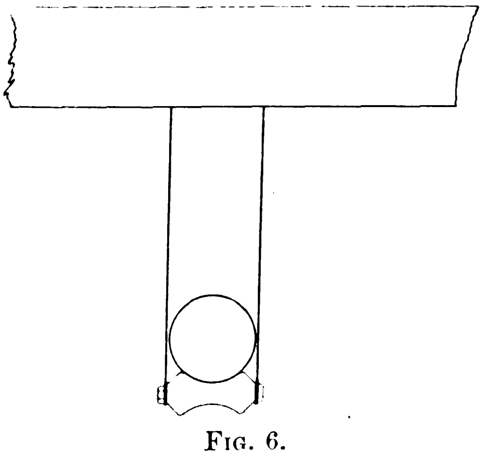

Fig. 6.

Where a pipe is located near a brick wall it may be carried on brackets, as illustrated in Fig. 7. These brackets should be made of wrought-iron and well braced. The iron ought to be from 4 to 6 inches wide to prevent the expansion of pipe from throwing it out of its proper position at right angles to the wall.

A suitable bolt holds the upper part of this bracket in place, while a short stud is sufficient for the lower end. I have noticed that some men think the latter requires a bolt as much as the former, but this is not correct, for the weight of pipe presses the lower part to the wall, only calling for a stud to prevent it from being accidentally moved out of place.

Fig. 8 illustrates a large pipe supported on brick piers where it can be carried near the ground. It shows one defect, which I have noticed in practice, as the rod is not supported close to the ends of roller, therefore the weight of pipe springs it out of place. This causes the roller to bear on its extreme ends only, resulting in very unsatisfactory service.

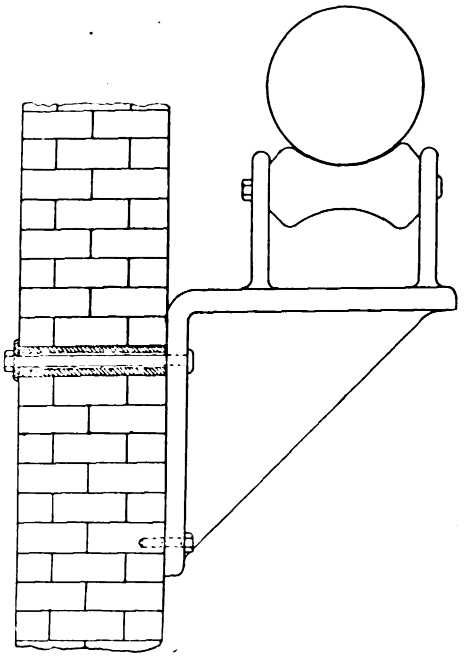

Fig. 7.

Fig. 9 shows an improvement along this line, as the rod is supported so closely that there is no chance for it to be deflected. All points considered, this is the best possible plan for supporting large and heavy pipe, as it is rigid on the foundations and at the same time allows the pipe to move easily in either direction as it is heated and cooled.

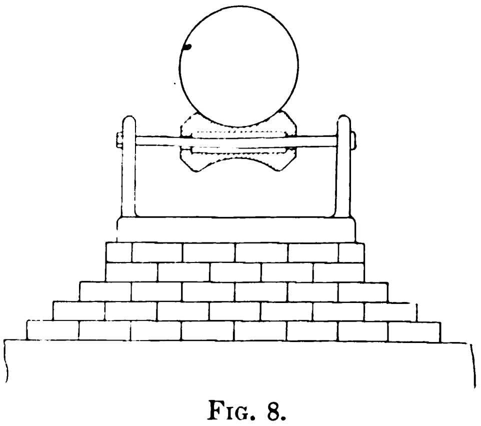

Fig. 8.

It is claimed that this is a class of rough work that does not call for special care, but this is not a correct idea, for although it does not require a nickel-plate finish it is necessary for it to be based on correct principles or trouble will follow. In hundreds of cases steam pipes leak badly, wasting away many dollars' worth of heat, and the engineers in charge find it impossible to keep the joints tight. Sunday may be the only available time in which to make such repairs, and in many cases only a part of this day can be spared, as the writer knows by experience, consequently if all joints are tight on one Sunday several may be leaking in two or three days, and perhaps all of them cannot be repaired on the following day of rest (?).

Why do some plants give so much trouble along this line while others are always in good repair? If first-class pipe and fittings are used and all pipe lines are properly supported, there will be no cause for complaint. It naturally follows that if good material is used and leaks are much in evidence, the trouble is due to unevenly supported pipe lines. I have assumed that the work was done by intelligent and honest mechanics in all cases, as that is the only basis for comparison.

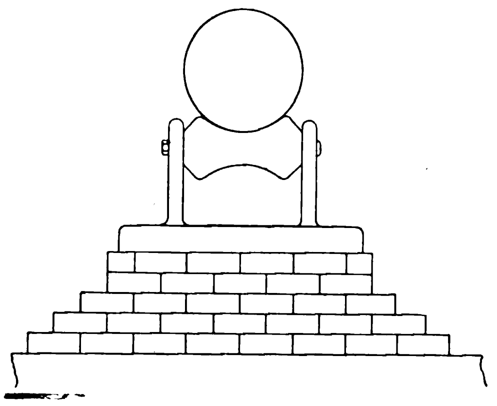

FIG. 9.

Due attention to suggestions made in this article will show that a pipe line must not only be put up level when cold but provision must be made for keeping it level when hot. The extra first cost necessary to secure the above desirable conditions is not worth considering when we note the money saved by their operation in practice. Dollars disappear very fast when there are many leaks in steam pipes under high pressure, and when the cost of hiring steam fitters to work nights, Sundays and holidays is added, the expense is great; therefore every reasonable precaution should be taken to avoid it.

The rollers shown in these illustrations are large in proportion to the pipes, but they are made so intentionally, because the larger they are in diameter the easier they move in service. Some rollers are too small to give good results, therefore this fault should be avoided.

ELECTRICITY LEAFLETS.

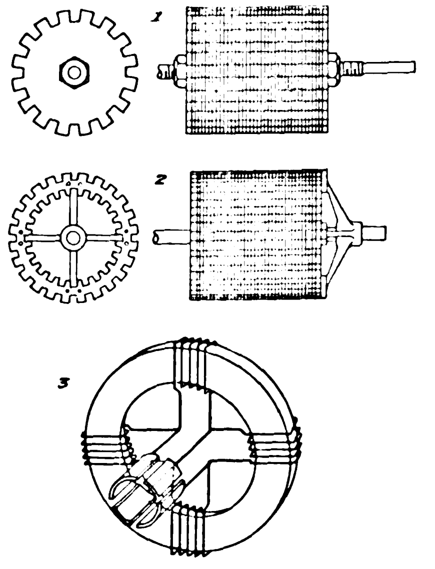
BY NEWTON HARRISON, E. E.

THE DYNAMO.

The Magnets of a Dynamo.—The three important parts of a continuous current dynamo are the armature, commutator and field magnets. The commutator is not required for an alternator. Around the armature core conductors are wound and firmly secured, their terminals ending in the commutator. Both commutator and armature are mounted on one shaft, by means of which the conductors are rotated in a magnetic field provided by the magnets. In some dynamos the coils of the magnets act almost directly on the armature, the magnetism passing through the end of the core which is curved to conform to the cylindrical shape of the armature and at the same time to permit it to rotate freely. In other dynamos the core is attached to a pole piece which may be of the same metal as the magnet core. If not, the core is generally of wrought-iron and the pole pieces of cast-iron. The ultimate purpose of the magnet winding is to force a certain amount of magnetism across from one pole piece to another. In order to get across, the magnetism must pass through the air-gap existing between one pole piece and the armature core and then again from the armature core through the air-gap back to the other pole. It is of the greatest advantage in a continuous current dynamo for incandescent lighting, for the magnetism, speed and armature turns to co-operate so advantageously that the volts produced by the machine for outside use remain unchanged.

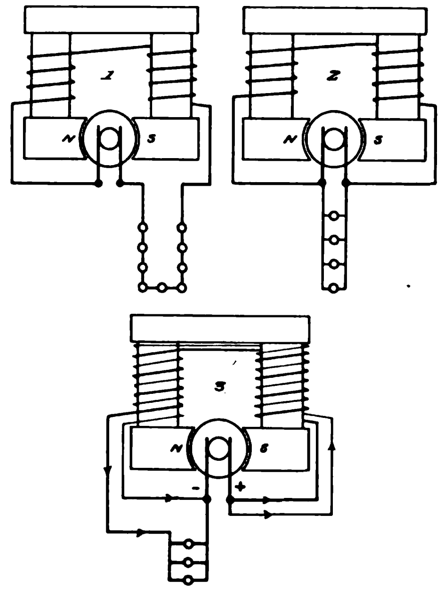
Construction of the Armature.—The armature core is not composed of a solid cylinder of iron; on the contrary, it consists of a great number of thin sheets of wrought-iron bolted together to give mechanical rigidity. If the armature was not composed of laminæ in this manner, it would act as a solid conductor moving in a powerful magnetic field and in consequence would generate a strong current. The effect of this current would be intense heat and a great waste of energy. Foucault was the first to suggest and to try the effect of subdividing the armature core at right angles to the lines of force in which it rotated. This practice is now followed out universally and is termed "lamination." The sheets of iron are stamped and in some cases thin paper is placed between the laminæ, although experience has shown that a coating of varnish or the oxide of the iron itself is all that is necessary to prevent electrical contact between plate and plate. Originally the conductors of direct current dynamos were wound on the outside of the core and held in place by bands of wire, but progress has been made both theoretically and practically by Pacinotti, and the armature cores are now slotted and the wires are wound in these slots and held, either by means of bands of brass wire surrounding the armature or by the employment of fiber strips slipping into and held by these slots over the wire they contain.

Kinds of Armature Cores.—Armature cores may be either simple cylinders, which have the wire wound completely around them, or they may be hollow inside and represent what are called ring and disk armatures. Both of these last named armature cores have the wire threaded through them instead of around from one side to the other across the ends. The cylindrical core is called by the name of "drum" armature and the ring by the name of "gramme" armature. The disk armature is sometimes called "the flat ring," to distinguish it from the other which is cylidrical in its character. Ring armatures are mounted on the shaft by means of spiders to secure them against slippage and vibration. The question of speed must be carefully considered in the construction of armatures and their mountings. The most solid type of armature and one largely in vogue at present is the drum. In the ring armature the conductors are wound around the ring; the consequence of this is that the inside wires are not generating electromotive force. In the drum armature the end wires crossing both bases of the cylinder are inactive and do not generate electromotive force.



1—Plate and complete core of a slotted drum armature. 2 Plate and complete core of a slotted ring armature. 3—A flat ring or disk armature.

Types of Dynamo Windings.—The manner in which a dynamo begins to generate EMF. is best understood with reference to the method of winding the fields and connecting them to the armature. There are three general types of dynamos, bearing the names of series, shunt and compound, according to their windings and connections. In the series dynamo the current generated in the armature flows out into the outside circuit, generally of lights, and returns to the dynamo through the winding of the fields. The circuit is therefore completed by the armature, lights and field being *in series* with each other. The shunt dynamo operates differently, the current from the armature passing through the outside circuit and returning to the armature, the field taking its current independently from the armature terminals or *in shunt*. The compound wound dynamo represents a combination of these two windings. It has a shunt field which takes its current from the armature terminals and an auxiliary series winding through which all the current of the machine passes in series with the entire outside circuit.



1—Connections of a series wound dynamo. 2—Connections of a shunt wound dynamo. 3—Connections of a compound wound dynamo.

Generating the EMF.—When a series, shunt or compound wound dynamo is set into operation, the action by which EMF. is developed and a current thrown into circulation does not take place instantaneously. The process is a self-regenerative one and depends in the first stage of its growth upon the presence of *residual magnetism* in the iron core and pole pieces of the machine. The least trace of magnetism in the pole pieces will enable the armature to generate a little EMF. This EMF. will send a minute current through the magnet windings, whether it be a shunt or series wound machine. The effect of this current is to produce a little more magnetism in the magnets and thus supply more lines of force to the armature to cut for the generation of more EMF. With more EMF. a stronger current circulates through the magnet windings, continually augmented in strength by the reinforcements of EMF. from the armature until a climax of development is reached when the dynamo is delivering its normal pressure. The process cannot go on indefinitely because the iron will not produce more than its proper quota of lines of force, and neither the speed nor conductors change in numerical value. Therefore when the iron becomes saturated and the speed and conductors remain unchanged the EMF. will not vary. It must be understood, however, for future reference that if any one of these three items undergo a change a corresponding change will be experienced in the development of EMF. A dynamo which can increase or decrease its magnetic field will proportionately affect the volts produced. If by any means, the speed remaining the same, the effectiveness of the conductors can be controlled in a dynamo, in like manner the EMF. will undergo increase or diminution.

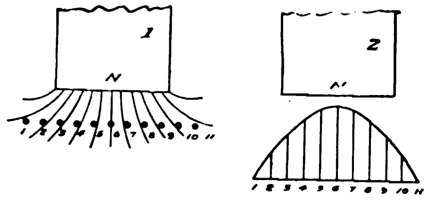
The Alternator.—The alternating current dynamo generates a current which cannot be used for exciting a magnetic field in the same manner as a current produced by a direct current machine. The electrical energy of an alternator consists of a rapidly reversing EMF. and current. The positive and negative poles of the dynamo are constantly reversing and the number of alternations per second depend upon the speed of the armature and the number of magnetic poles the conductors move past per second. The magnetic field is obtained from the current of a small continuous current dynamo called the "exciter." This machine may be permanently attached to the alternator or it may be merely belted to the shaft supplying both with power. Its entire function is to supply current to the field magnets of the alternator, which current, it must be distinctly understood, is not always obtained in this manner. It is sometimes obtained from an auxiliary or independent winding on the alternator armature which is connected to a commutator and thus makes the alternator self-exciting. The general plan, however, is to keep the exciter separate in the manner described. An alternator generally consists of four or more poles or magnets. A few figures are given in the following table showing how the reversals of current are due to the number of poles and the speed:

Revolutions per second.	Pairs of poles.	Complete reversals of current per second.
10	1	10
15	1	15
20	1	20
25	1	25
30	1	30
10	2	20
15	2	30
20	2	40
25	2	50
30	2	60
10	4	40
15	4	60
20	4	80
25	4	100
30	4	120

The idea represented here is as follows: A conductor moving past a north pole develops a current opposite in direction to that developed when moving past a south pole. A complete cycle only occurs when the wire sweeps past a north and south pole in succession. In this case the wire generates an EMF. which rises from zero to its full value, and drops again to nothing just the instant before it passes under the opposite pole. When passing under the opposite pole the process is repeated in a reversed direction and when completed the wire is about to enter upon the same cycle again. This is therefore called a complete reversal of current and is due to a conductor passing *one pair of poles*. If it passes a pair of poles 10, 15, 20, 25 or 30 times a second, just so many times will a complete reversal of EMF. be generated. Multiplying the revolutions per second by the number of pairs of poles will give the reversals, or as it is generally called the "frequency" of the current.

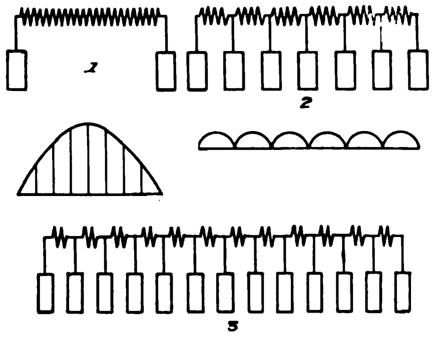
A Wave of EMF.—The function of the commutator and its relation to the impulses of EMF. generated in the armature can be best understood by a better acquaintanceship with what is called "a wave of EMF.." If any dynamo, whether it be a bipolar or multipolar, every conductor passing the poles has an EMF. generated in it which is in strict proportion to the lines of force it cuts.

If the EMF. of a conductor passing in front of a north pole is estimated in a series of positions, the product of the number of lines of force by the speed of the conductor will give the amount of EMF. developed. Suppose the EMF. is measured while the conductor is rapidly



1—Positions of the conductor. 2—Curve of EMF. corresponding to the positions of the conductor.

passing through these positions, then, at each point, the EMF. will differ, provided the rate of motion is uniform, because the lines of force are so distributed that in their case at least no uniformity exists. If use is made of such data as can be obtained in this manner, to graphically represent the entire process; then, by letting the length of vertical lines be a measure of the EMF. developed at that instant, and a base line be proportioned to the time during which these various electromotive forces are produced, a curve can be drawn through the extremities of the vertical lines which will adequately picture the rise, full growth, and fall of the EMF. As the wire moves on to pass beneath a south pole, the generating process is repeated and the result in consequence is a wave of EMF. in one direction under a north pole and a wave of EMF. in the opposite direction under a south pole. The more abruptly these waves are produced and the greater the EMF. they represent the more difficult it is to obtain what is commonly called a continuous current. If heavy impulses, due to a great many turns acting co-operatively, are rectified by means of a commutator, which would, under the circumstances, consist of comparatively few segments, then such a current would represent a series of direct pulsations. The current is direct but not, in the strict sense of the word, continuous. It is like the stream which issues from a powerful force pump without a pressure chamber—the stream is all directed one way, but occurs in increasing and diminishing spurts. If, on the other hand, the armature conductors are so arranged that only a few are connected to each commutator segment, then there would be many commutator segments required. The result of this principle would be that the abruptness and magnitude of the EMF. of a few conductors connected together would bring the current down to a gentle ripple approximating uniformity. It would still pulsate, but with small pulsations, which is the purpose of designers in laying out continuous current machines for incandescent lighting.



1—Heavy impulses with two segments. 2—Small impulses with seven segments. 3—Very small impulses with thirteen segments.

Connecting Coils to a Commutator.—Carrying out these ideas in practice in connecting coils to a commutator it is needless to state that if an armature core was wound with 1,000 turns of wire, by means of which, when revolving at 1,000 revolutions per minute in a magnetic field, 100 volts were generated, that a commutator consisting of only two segments would cause destructive sparking. It is only reasonable to believe that if the commutator segments were increased to 4, 6, 12, or in fact to something like 50, and the 1,000 conductors were divided up between them that the sparking would be very much reduced. In other words, the commutator segments, and the volts produced by the armature conductors, must be proportioned with regard to two things: first, the uniformity of the current; second, the sparking at the dynamo brushes.

Heavy pulsating currents are employed for high tension arc lighting. Direct currents of a uniform character are employed for low tension incandescent lighting. In the illustration the change of the curve from a heavy impulse to a ripple-like flow is shown through the use of a greater number of commutator segments. Carrying out this idea to its practical limitations would give a current so uniform in character that it would compare with the discharge from a storage battery through a fixed resistance.

HIGH-TENSION SWITCHGEAR.*

BY L. ANDREWS, M.I.E.E.

One or two serious accidents with high-tension switchgear of compact design have made engineers realize that, efficient and convenient though such switchgear has shown itself to be under normal conditions, the margin of reliability must be further increased in view of the paramount importance of preventing interruptions in the supply of current.

The most revolutionary departure from former practice, to be found in nearly every switchboard that has been erected during the past year, is the dividing of the controlling system up into a number of entirely separate units, each section being so isolated from adjacent sections as to render a spread of fire from one unit to another practically impossible. This entails the operation of switches placed at a distance from a central operating panel or keyboard.

American practice has tended towards the almost universal adoption of electrical control, while on the Continent the tendency has been to favor mechanical control. An excellent example of this is the switchgear controlling the 13,000-volt generators, etc., at Paderno, which has now been in successful operation for about seven years.

One argument that is sometimes used in favor of electrical control is that a large mechanically-operated three-phase switch cannot be closed sufficiently quickly for synchronizing. This argument certainly does not apply to 1,000 kw. generators or under.

Again, we are told that mechanically-operated switches must be tripped electrically, and might as well be operated electrically entirely. But merely to trip a switch that is closed by hand is a very simple problem compared to that of constructing a switch to be opened and closed electrically.

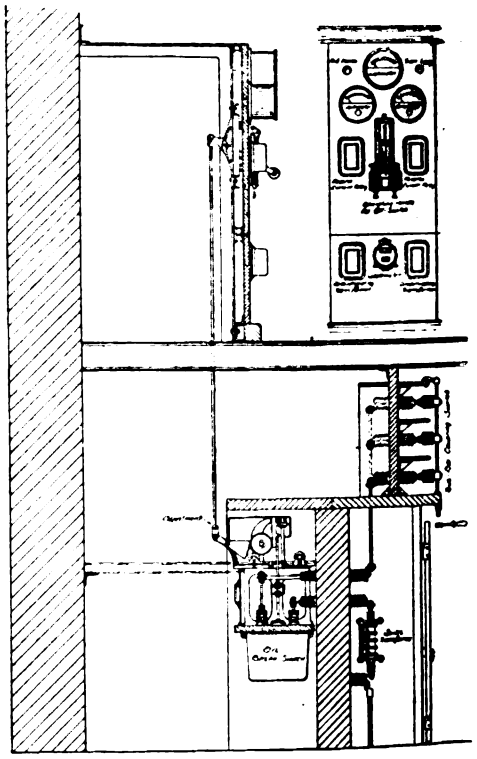


FIG. 1.

Another advantage claimed for electrical control is that it enables the high tension switches to be placed directly opposite the generators they control, as the operating keyboard can be compactly arranged in a very small space, but even this is a doubtful advantage. It seems much better practice to bring the main cables from the generators to one point of the building, at which center all the high tension switches are placed.

Electrical operation is certainly more satisfactory for controlling switches placed a long distance from the operating board.

So far we have considered the question of mechanical versus electrical control in the abstract only. A brief description of the 6,000-volt mechanically-operated boards, now in course of erection at Poplar, will show how the problem has been dealt with in this case.

---

*Abstract of paper read at the meeting of the Manchester Section of the British Institution of Electrical Engineers, December 13, 1904.

Fig. 1 is a sectional view of the high-tension board in the main generating station. The construction and arrangement of the high-tension boards in the sub-stations is precisely similar.

The three-phase high-tension oil break circuit-breakers are fixed in brickwork cells on the ground floor. Each unit or section is by this means efficiently isolated from adjacent sections, and a spread of fire from one section to another is rendered practically impossible.

As this confining in narrow brick cells is apt to make some of the back connections inaccessible (and the importance of accessibility cannot be over-rated) provision has been made for withdrawing each circuit-breaker from its cell for overhauling, cleaning and inspection. For this purpose the circuit-breaker is mounted on rollers which rest on brackets fixed to the partition walls of the cells. Extension rails are provided, along which the circuit-breakers may be withdrawn.

The connections at the back of the circuit-breaker cells, together with the series transformers from which current for the instruments and relays, etc., is obtained, are also inclosed in brick cells.

No high tension cables are carried into the circuit-breaker cells, the necessary connections being made by copper rods carried through insulators set in the wall.

A detail to which considerable attention was paid in designing this board is the arrangement of the bus-bars. Each bus-bar is isolated from adjacent bus-bars by horizontal slate slabs, and to guard against any risk of an arc being formed that might destroy this slab, and so short-circuit the bars, precautions have been taken that effectually obviate any possibility of the circuit being opened in either of the bus-bar compartments.

Isolating plugs are provided to enable any circuit-breaker to be completely disconnected from the bus-bars, before working upon it. These plugs should, of course, not be removed when carrying current. In the event, however, of an attendant withdrawing a wrong plug by mistake the circuit will not be broken in the bus-bar compartment, but on the other side of a thick stone slab. As the back contact plugs are again isolated from the contacts of other phases (in this case by vertical slate slabs), the damage is bound to be confined to that particular contact. As a further precaution, the plugs are so constructed that they cannot be withdrawn more than 2 inches from the back contacts, so that should an arc be started it will not be a long and destructive one, and the attendant will thus be able to replace the plug and open the main circuit-breaker before much damage is done.

Another question, upon which opinions differ at present, is that of the necessity of separating the contacts of one phase from those of opposite phases in the main circuit-breakers. Some engineers consider that if the circuit is broken under oil the contacts of all phases may be contained in one vessel. Others go to the opposite extreme, and divide each phase from adjacent phases by brick walls.

It appears, however, that all that is actually required is that the contacts of the different phases should be contained in separate oil tanks, the latter being insulated from the high tension connections and from earth.

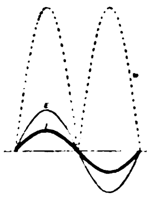

FIG. 2.

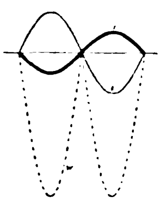

FIG. 3.

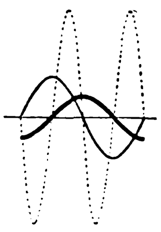

FIG. 4.

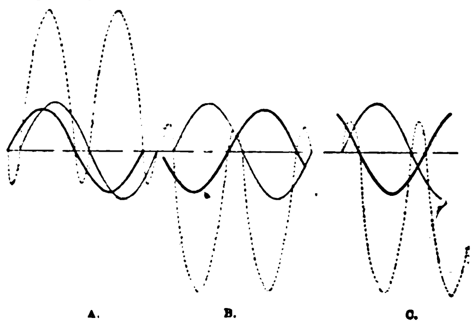
It is no longer necessary to draw attention to the fact that neither fuses nor excess-current circuit-breakers should be used between generators and the main bus-bars, but that reverse-current circuit-breakers should be used in this position. Nearly every switchboard that has been erected during the past year has been so equipped. The only danger now is that alternating current discriminating devices will be brought into disrepute, through being misunderstood. Experience has shown that some of these devices are capable of behaving in a most unexpected manner under the abnormal conditions that are liable to arise when a serious breakdown on any part of the system occurs.

As long as a generator is supplying current to feed a non-inductive load, the phase relations between current and EMF. will be as indicated respectively by the curves I and E, Fig. 2, and by compounding these curves we obtain the curve W, representing the torque or pull due to these combined forces. This pull may obviously be used to hold the cut-out in its closed position. If, now, one of a number of generators working in parallel should fail—due, say, to a bearing seizing—current will flow into this generator, tending to drive it as a motor, and this current will be approximately 180 degs. out of phase with the bus-bar EMF. That is to say, the phase relations will now be as shown in Fig. 3. We see that the direction of the pull is now reversed, and it may therefore be used to release the cut-out.

Let us now suppose that a generator, protected by cut-outs constructed as above, loses its field; current will again feed back into it from the bus-bars and other generators, but this current will not be 180 degs. out of phase with the bus-bar EMF., because its energy is not in this case expended in driving the faulty generator as a motor. The speed of this generator is being maintained by its engine. It is evident, therefore, that the reverse current must, under these conditions, be practically wattless. The phase conditions may now be represented by the curves shown in Fig. 4. It will be seen that the current curve is approximately 90 degs. in advance of the EMF. curve, and the pull or torque is alternately positive and negative, and being just equal and opposite, their combined effect is nil for any current.

A device designed to deal with a reverse current, due to a failing prime mover, is thus useless for isolating a generator having an open circuited field.

By adjusting an inductive resistance in series with the shunt circuit until the shunt current lags about 45 degs. when the series current is feeding a non-inductive load, the phase relations in the cut-out device are altered to those shown by the respective curves in Fig. 5, A representing the conditions when the generator controller is feeding a non-inductive load, B when the prime mover fails, and C when the generating field is open circuited.



A. B. C.

FIG. 5.

(*To be continued.*)

Everett-Moore Trustees to be Released.

The affairs of the Everett-Moore Syndicate have been practically closed up and in a few days the trustees will be released. It was just three years ago that announcement was made that the street railway syndicate was in trouble. Its liabilities exceeded $17,000,000. The debts, it is said, have all been liquidated.

Proceedings of the Northwestern Electrical Association Convention.

Nearly 100 members were in attendance at the 13th annual convention of the Northwestern Electrical Association, held at the Hotel Pfister, Milwaukee, Wis., January 18, 19 and 20.

The convention was called to order on Wednesday morning at 11:45 by President T. F. Grover.

The calling of the roll was dispensed with, and the minutes of the last meeting, having been printed in book form, were accepted and approved.

THE PRESIDENT'S ADDRESS.

President Grover, in his address, stated that it was the 12th annual convention of the Association that he had attended and that he had profited and enjoyed each and every meeting. Among other things President Grover said:

"The past year, I believe, has been a successful one to the great majority of the central stations as well as to the street and interurban railway interests. Electricity is constantly reaching out and finding new industries to conquer. At the semi-annual convention of this Association held at St. Paul in 1894, as I remember, the attendants wore a badge on which was inscribed, 'The man who says electricity is in its infancy shall be hung by his neck until dead, dead, dead.' Very few of us at that time, however (although but 10 years ago) realized the steady advance that has been made in electrical industries.

"The last year will go down in history as an eventful one in electrical industries, one of the more important achievements being the opening of the New York Subway, which would not have been possible without the aid of electricity. The perfecting of the single-phase railway motor has done much for the interurban railway, as it permits the transmission of electrical energy for greater distances, and by the use of transformers does away with expensive sub-stations and opens the way for the speedy conversion of steam railways to electric.

"But little has been heard of 'municipal ownership' in the territory covered by this Association during the past year. Municipal plants now in operation have failed to show the large profits predicted, and it is easily to be seen by all fair-minded business men that a corporation properly managed operating commercial lighting, power and railway plants, can, and does furnish better and cheaper street lighting than can be furnished independently by any political body."

The President—The next order of business will be the Secretary-Treasurer's report.

The report was submitted by Mr. Mercein who reviewed the St. Louis meeting and also stated that 22 applications for membership had been received during the year.

A recess was then taken until 1:30 P.M.

WEDNESDAY AFTERNOON SESSION.

The convention was called to order at 2 o'clock.

The President appointed as nominating committee J. H. Harding, O. M. Rau and R. N. Kimball.

Membership Committee—S. B. Livermore, P. H. Korst and W. B. Jackson.

The report of the legislative committee was then presented by the chairman, Mr. S. B. Livermore, as follows:

"So far as the sub-committees have reported there has been nothing of much moment to the electrical business enacted or proposed since our last meeting.

"The committee from Iowa reports an act covering malicious mischief and trespass, which I append here to be read in full.

"The committee from Illinois reports no bills detrimental to electrical interests.

"The committee from Indiana reports a bill for an act concerning municipal corporations pending before the State Legislature of Indiana, and expects to have a copy of same to read to convention.

"The committee from Michigan does not reply to my request for a report.

"The committee from Wisconsin also makes no report although ample time has been given it to reply to my request for a report. In relation to Wisconsin, I append the heading of Governor La Follette's new bill on taxation of electric and gas properties, street railways and life insurance companies, which bill the Wisconsin members can procure from their representatives for reading.

"The committee from Minnesota reports no meeting of Legislature last winter, and so far as can be learned nothing important has been introduced this term.

"This covers the States except Michigan, and there has been almost nothing done to change the existing laws governing our business."

A paper by Mr. W. B. Jackson of Madison, Wis., was then read on the subject of the "Successful Joint Utilization of Several Small Water Powers by the Janesville Electric Company."

Mr. Jackson's paper was received with great applause.

Mr. Korst—There has been an important omission made in the paper just read, and that is, that Mr. Jackson has been our consulting engineer and designing superintendent of our new plant and I think it is proper that the members should know that.

Motion made, seconded and unanimously carried thanking Mr. Jackson for his paper.

Mr. Almert—While they are distributing Mr. Rau's paper, I would like to suggest that Mr. Jackson furnish, to be published in the proceedings, a diagram showing the arrangement of these different units, different clutches, etc.

The President—You wish Mr. Jackson to give some diagrams showing the connection of clutches, switches, etc., in the Janesville plant?

The Secretary—You mean add that to his paper, or print them with the proceedings?

Mr. Almert—Yes, he has blue prints in his office showing that, and I think it would be very valuable to some of us.

The President.—With Mr. Jackson's approval that will be done.

Mr. O. M. Rau of Milwaukee then read a paper on the subject of "A. C. and D. C. Distribution."

Before reading his paper Mr. Rau said: "I have been engaged in an extensive investigation as to the relative advantages of A. C. and D. C. distribution, and an account of that investigation forms the subject of my paper."

A long discussion followed the reading of the paper.

The secretary then read a paper on the subject of "The Rating of Arc Lamps," written by Prof. George D. Shepardson, of Minnesota University.

The President then introduced Mr. James Wood Pogue, manager of the Milwaukee branch of the Sheldon School of Salesmanship, who delivered a long address, which he concluded by relating the following little story illustrating what is meant by the power of salesmanship: "It is an exceedingly simple story in a way, and yet it is one which contains a thought that everyone of us can profit by, particularly as it comes from a lady. Two ladies, one named Mary and the other Elizabeth, were born on the self-same street about the self-same time. They grew up as girls together, went to school together, and one being wealthier than the other, was sent to college. They were in social life together, but drifted apart. Finally one day they met after years, and

Mary said to Elizabeth, 'I see you are about to be married again,' and she said 'Yes, I believe that is true,' and Mary said: 'Elizabeth, I can't understand it. You and I were born about the same year, we grew up together, we lived together, were friends together, but I went off to college and you could not go. I have more money than you have, and I believe I am as good looking as you are, and yet you have had two husbands and are about to get a third, and I cannot get one at all. Will you explain the reason?' And Elizabeth thought a while, looked her friend kindly in the face, and with a smile said: 'Mary, I will tell you, it is not just being born, and it is not just living on the same street, and it is not just going to college, nor having money, nor beauty, but the secret of it, Mary, is this, it is the come hither in your eye that makes the difference.' And that is what it is in the business world. I thank you for your attention." (Applause.)

The convention then adjourned until 9:45 A.M. next day.

Thursday Morning's Session.

The meeting was called to order at 10:25 by the President, who announced the first order of business would be the discussion of the paper of Mr. Williams on "Distribution and Dollars."

Nearly all the members joined in the discussion.

The President—We will listen to the paper by Mr. E. P. Warner, of Chicago, on the subject of "Series Alternating Arc Lamps."

After his paper had been read Mr. Warner said: "I will say in this connection that there are quite a variety of completely disconnecting switches on the market, all of which are said to be safe devices, and I have no doubt that in many cases people have made use of them to handle lamps and trusted their lives to these devices, thinking they did completely isolate the lamp from the circuit, but I have yet to see a device that I would advise managers to use and permit their employes to stand on the ground and handle a lamp even when the switch was operated."

The President—I would suggest that the matter of the discussion of this paper be laid over till this afternoon and that the nominating committee make its report before we go into executive session.

Mr. Harding—The nominating committee begs leave to submit the following names for the officers and directors for the next year:

President—C. H. Williams, Madison, Wis.

First Vice-President—Roger N. Kimball, Kenosha, Wis.

Second Vice-President—H. Almert, Oak Park, Ill.

Secretary and Treasurer—Thomas R. Mercein, Milwaukee, Wis.

Directors—P. H. Korst, Janesville, Wis.; Ernest Genzenbach, Sheboygan, Wis., and H. J. Gille, St. Paul, Minn.

Mr. Livermore—I move that the report of the nominating committee be received and filed and the Secretary instructed to cast the ballot of the Association for the election of the nominees.

Motion seconded, unanimously carried and so done.

Secretary Mercein—I simply think it due to state this, that I have served for years under a number of presidents, and have found none more helpful and none who have taken more interest or given more efficient aid to the secretary than the retiring president, Mr. Grover, and I move that he be given a vote of thanks for his active and efficient service during the past year.

Motion seconded and unanimously carried amid great applause.

President Grover—I thank you, gentlemen. Mr. Lord, will you please escort the President-elect to the chair?

Mr. Lord—(escorting President-elect Williams to the chair). I take great pleasure in presenting to you Mr. C. H. Williams, your new President. (Applause).

Mr. Williams—I thank you sincerely for the honor you have conferred on me in making me your executive officer. I feel that you have placed a great responsibility upon somewhat inexperienced shoulders, but with your help I will try to make up in activity what I lack in experience. (Applause.)

The Association then went into executive session and shortly after adjourned until afternoon.

Thursday Afternoon's Session.

At 2 o'clock the convention was called to order by the President.

The President—We have a long programme to get out this afternoon, and the next paper is by Mr. W. T. Goddard, on "High Tension Practice."

This was a lecture consisting largely of lantern slides (described by the speaker).

A paper by Mr. Clarence Renshaw, of Pittsburg, was then read on "Single Phase Railways and Their Possibilities." This paper was also illustrated by stereopticon slides.

The President—We will now listen to Mr. McCarthy's paper on the "Economy and Working of the Diesel Engine."

Mr. J. W. Shuster, of the University of Wisconsin then read a paper on the subject of "Motors."

Adjourned to 10 o'clock A.M. next day.

Friday's Session.

The convention was called to order by the President, and there being no further business an adjournment was taken sine die.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED JAN. 17, 1905.

Electric Railways and Appliances.

780,120. Electric-Railway Signal. Elwood W. McGuire, Richmond, Ind. Filed Feb. 6, 1904.

780,194. Sheath for Trolley-Wheels. Santos Jurado, New York City, assignor, by mesne assignments, to William Fechtenburg & Co., same place. Filed March 25, 1904.

780,316. Third-Rail Insulator. Paul Winsor, Weston, Mass. Filed June 10, 1904.

780,386. Electromagnetic Traction Device. George W. Thompson, Melrose, Mass. Filed July 26, 1904.

780,388. Trolley. Gutie H. Tuttle, Shorter, Ala. Filed Oct. 26, 1904.

Electric Lights and Appliances.

780,065. Electric Lamp. Elijah R. Roberts, Bellevue Pa., assignor to George Westinghouse, Pittsburg, Pa. Filed Dec. 15, 1900.

780,087. Incandescent-Electric-Light Bulb. Martin C. Burt, Chicago, Ill., Filed March 4, 1904.

780,222. Electric-Lighting System. Granville E. Palmer, Boston, Mass. Filed June 1, 1903.

Electrical Machinery and Apparatus

780,024. Circuit Making and Breaking Relay. Frank Conrad, Edgewood Park, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed Dec. 29, 1902.

780,045. Single-Phase Alternating-Current Motor. Benjamin G. Lamme, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed May 3, 1904.

780,046. Armature-Winding for Electric Motors. Benjamin G. Lamme, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed May 3, 1904.

780,047. Electric Motor. Benjamin G. Lamme, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed June 30, 1904.

780,048. Single-Phase Alternating-Current System of Distribution. Paul M. Lincoln, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed May 3, 1904.

780,055. Electrical Controlling Apparatus. Frank C. Newell, Wilkinsburg, Pa., assignor to the Westinghouse Air Brake Company. Filed May 5, 1902.

780,058. Controller for Electric Motors. Thomas S. Perkins, Wilkinsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed June 24, 1902.

780,104. Electric Controlling Apparatus. John D. Ihlder, Yonkers, N. Y., assignor to the Otis Elevator Company. Filed July 31, 1903.

780,221. Electric Igniter. James W. Packard, Warren, O., assignor to the Packard Motor Car Company, Detroit, Mich. Filed Jan. 10, 1903.

780,275. Current-Motor. George D. Foster, Preston, Ia. Filed Nov. 30, 1903.

Telephones and Telephone Apparatus.

780,093. Telphone System. Alfred Ekstrom, Stockholm, Sweden, assignor to the Aktiebolaget L. M. Ericsson & Co., Stockholm, Sweden. Filed Dec. 17, 1902.

780,439. Electric-Circuit Closer. John K. Norstrom and Henry M. Graif, Chicago, Ill., assignors to the Automatic Telephone Company, same place. Filed June 18, 1903.

Miscellaneous.

780,191. Electrochemical Separation of Metals. Woolsey M. Johnson, Hartford, Conn. Filed June 23, 1902.

780,228. Electric Stove. Earl H Richardson, Ontario, Cal., assignor, by direct and mesne assignments, to the Pacific Electric Heating Company, same place. Filed Jan. 25, 1904.

780,322. Electric-Dental Instrument Holder. Monroe N. Callender, San Francisco, Cal., assignor to J. W Rooch, same place. Filed Nov. 3, 1904.

780,365. Storage Battery. Joseph Melzer, Cleveland, O., assignor to the Osborn-Morgan Company, same place. Filed April 2, 1904.

THE TELEPHONE WORLD.

Telephone Rates to be Incr

Although the official announcement has not been made, it is understood that telephone rates in Cortland, N. Y., will be increased on or about July 1.

The Cortland Home Telephone Company has made large expenditures of late in erecting a new building and installing a new switchboard. The higher rates are necessary to keep the service at the top level of efficiency.

The proposed changes in rates follow: Business 'phones will be advanced from $24 to $36 a year; residence 'phones from $12 to $18; two person lines will be raised from $12 to $15 a year.

The work of fitting up the new building is progressing rapidly, and it is expected that it will be ready for occupancy by the latter part of February.

Mexican Telephone Systems.

The work of constructing a telephone line between San Luis Potosi and San Felipe, Mexico, has been completed. The Mexican Government has declared forfeited the concession which was held by J. Woesner, of Saltillo, for the construction and operation of a system of long-distance telephone lines in Northern Mexico. It is stated that Mr. Woesner was unable to comply with the terms of the concession. A part of the system was constructed and is in operation.

The executive committee of the Ohio Independent Telephone Company met in Columbus recently to perfect arrangements for a definite understanding among the several Independent interests regarding the measure to be adopted to meet the competition of the opposing company. Among those present was J. C. Reber, of the Home Telephone Company of Dayton.

The Rural Telephone Company of Port Byron, N. Y., and vicinity, was recently organized with officers as follows: President, C. W. Weston; vice-president, F. S. Root; secretary and treasurer, H. R. Warren; board of directors: H. R. Warren, F. A. Mead, Addison Cole, John Monroe, T. M. Crane, F. S. Root, all of Port Byron, and Dr. Sawyer, of Montezuma. It is capitalized at $50,000, each share being $50.

A movement is said to be on foot in Johnstown, N. Y., to organize a new telephone company in opposition to the Glen Telephone Company, which recently increased rates. It is said that a number of capitalists of that place have been interviewed with regard to the matter by a representative of an Albany Independent company, and that he has been given considerable encouragement.

When the telephone company in Ogdensburg, N. Y., gets established in its new exchange office it will begin installing free trial 'phones throughout that city.

The Delaware & Atlantic Telegraph and Telephone Company of Camden, N. J., has amended its certificate, showing a capital of $397,945 fully paid in.

The Marne & Elkhorn, Ia., Telephone Company has increased its capital to $15,000.

To Cut Telephone Rates.

The Syracuse, N. Y., Telephone Company, in annual session lately, elected the following officers: President, J. J. Jermyn; vice-presidents, H. W. Plumb and Arthur R. Peck; treasurer, R. G. Jermyn; general manager, F. M. Potter, Jr. These officers together with J. L: Wentz, H. A. Moyer and A. A. Howlett comprise the board of directors. The company is planning to place into effect a rate of $10 annually for telephone service, and a cent a message above the $10. This is looked upon as a move to reduce the rates. The present rates are as follows; Private lines, business, per month, $3; residence, $2; party line, business, $2.50, and residence, $1,50. The company was authorized to increase the bond issue from $300,000 to $1,000 000 and the proceeds from the sale of bonds will be used in the construction of a new plant. The site for the building has not been decided upon.

Gives Some Telephone Facts.

Interesting facts in the development of the telephone system were contained in the lecture recently delivered to the Franklin Institute by C. J. H. Woodbury, assistant engineer of the American Telephone & Telegraph Company. These were some of the things he emphasized;

"The telephone service now knits together in one system more than 26,000 settlements throughout this country.

"Time for telephonic transmission over 1,064 miles between Boston and Chicago is .006 of a second, while the distance the voice is transmitted through the air in that time is 6⅓ feet.

"In the Bell telephone system there are approximately 6,300,000 poles, and about 1,000,000 are required yearly for replacement and for extension of lines"

At the annual meeting of the stockholders of the Union Electric Telephone & Telegraph Company to be held next month a proposition to furnish a toll service with cities throughout Illinois having Independent lines will be acted on. All Independent lines in the State it seems are endeavoring to get together on some basis by which messages can be interchanged over the various lines.

At the annual meeting of the Upper Lisle, N.Y., Telephone Company the following officers were elected: President, Frank Brannan; secretary, Arthur Rooks; treasurer, Martin Sherwood; directors, John Stalker and George A. Landers.

A new telephone system is to be installed in Tiverton, R. I., soon by the Strowger Automatic Company. Automatic 'phones of an improved style are to be put into Little Compton, Tiverton, Four Corners and Tiverton proper.

A. B. Crawford, formerly of Elgin, Ill., has purchased a private telephone line at Nunda in that State which he will install as soon as possible.

The Farmers' Telephone Company of Hopedale, Ill., has increased its capital stock from $5,000 to $20,000.

There is prospect of an extension of the telephone service in the rural parts of Dudley, Mass.

Census Report on Telephone and Telegraph Systems.

The Bureau of the Census has recently published the fourth of a series of reports on the generation and utilization of electric current during the year ending December 31, 1902. The present bulletin concerns telephones and telegraphs.

Although the commercial telephone has developed entirely during the past 30 years, the bulletin states that it is now of vastly greater importance than the telegraph. The extension of the long distance service, the introduction of the commercial systems into rural districts, the establishment of Independent rural lines, the development of such lines, in some instances, into mutual systems with an exchange and more extensive service, and the rapidly increasing use of the telephone in private dwellings, all point to a growth of the industry that can hardly be realized. In 1902 the wire mileage operated by commercial and mutual telephone systems together constituted 70.6 per cent. of the combined mileage for such systems and commercial telegraph systems, and these same telephone systems gave employment to 70.7 per cent. of the combined wage-earners, paid 65.5 per cent. of the wages, received 68 per cent. of the revenue, and paid 67.8 per cent. of the expenses.

At the census of 1880 the telephone industry was in embryo, few commercial companies being in operation prior to that year. The financial interests represented were relatively of great importance, but the amounts were comparatively insignificant as compared with the totals for 1902.

The number of miles of wire in use in 1902 was 141 times, and the number of telephones nearly 43 times as great as in 1880. The number of miles of wire, and the number of instruments operated in 1902 by the Independent rural lines, which in 1880 were not in existence, were in excess of the totals for the entire industry in the earlier year.

In 1880 the population of the United States was 50,155,783, and the number of telephones of all kinds was 54,319, giving an average of 923 persons per telephone; the population of continental United States in 1902 is estimated at 78,576,436, and the number of telephones operated in that year was 2,315,297, giving an average of 34 persons per telephone.

The commercial systems in 1902 numbered 3,107—three times as many as the mutual systems, of which there were 994.

Telephone Incorporations.

The Rose Telephone Company, New York City. Capital stock, $15,000. Incorporators: H. K. Rose, Mary J. Rose, South Kortright; C. E. Hanford, Hobart.

The Guarantee Telephone & Equipment Company, Chicago, Ill.—to manufacture telephones and electrical supplies. Capital stock, $2,500. Incorporators: L. Anderson, Albert Dace and Donald E. Turner.

The Bremen Telephone Company, Bremen, O. Capital stock, $5,000. Incorporators: H. M. Shelhamer, S. E. Shull, J. C. Shaw, G. E. Turner, M. E. Osborne, L. E. Sherlock and J. S. Brown.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Bayonne, N. J.—The project of Mayor Brady, to have this city erect and operate its own electric plant for lighting the streets, was recently indorsed by the board of trade.

Bay City, Mich.—The board of electrical control is considering bids for the erection of the new commercial lighting plant.

Becker, Minn.—This city is to have an electric light plant.

Bridgeville, Pa.—This town will soon have its streets lighted by electricity.

Burlington, Ia.—Plans are on foot to organize a stock company for the purpose of putting in an electric light plant.

Canastota, N. Y.—It is quite probable that the citizens will vote on the proposition of installing an electric light plant.

Cayuga, Ind.—The town board is considering the establishment of an electric light plant.

Chicago, Ill.—Plans are being prepared by Sargent & Lundy, Exchange Building, this city, for a large electric lighting plant at Waukegan, for the North Shore Electric Company.

Columbus, O.—The board of managers of the penitentiary have decided to install electricity for lighting purposes.

Covington, Ga.—This city has under consideration the re-establishment of its electric light plant, recently destroyed by an explosion entailing a loss of $12,000. Address J. F. Henderson.

Creston, Ia.—W. H. Schott is preparing plans for a gas, electric light and heating plant.

East Moline, Ill.—It is reported that P. C. Dunbar is interested in the construction of an electric lighting plant here.

Florence, Col.—The Arkansas Valley Electric Light Company contemplates enlarging its plant.

Forrest City, Ark.—Eugene Williams, cashier of the Bank of Forrest City, has purchased the electric light plant from Captain Head, for $10,000.

Fort Valley, Ga.—The citizens will vote about March 1, to consider the question of establishing a municipal electric lighting plant. J. L. Fincher, mayor.

Fort Worth, Tex.—George Armstrong has purchased a site on which he will build an electric lighting plant.

Gifford, Ill.—An electric light company has been organized here by Dr. T. J. McKinney, J. D. Morse and others, and an electric light plant will soon be erected.

Homer, La.—This town has under consideration the establishment of an electric light plant.

Jacksonville, Ore.—A franchise has been granted to the Condor Water & Power Company to furnish electric lights for this city.

Jefferson City, Tenn.—A movement is being made by the Jefferson City Electric Light Company to replace the plant burned a short time ago.

Knoxville, Tenn.—The city council has passed a resolution favoring the municipal ownership of the city electric light plant.

Lamoille, Ill.—An electric lighting plant will be installed here.

Middlebourne, W. Va.—J. W. Jackson contemplates the establishment of an electric light plant.

New Albany, Miss.—This town will hold a special election January 31, to pass on the question of issuing $20,000 bonds for the construction of waterworks and electric light plants.

Northville, Mich.—The common council has granted a 30-year franchise to C. A. Ward, of Ann Arbor, for furnishing electricity for lighting the streets, and power for factories in this city.

Oshkosh, Wis.—The Duran Light & Power Company's plant of this city has been destroyed by fire. The loss is said to be $16,000.

Paris, Ill.—The capital stock of the City Gas & Electric Company has been increased to $60,000, and will be expended in improving the plant.

Pittsfield, Ill.—The Pittsfield Electric Light Company contemplates erecting a new power house with more machinery, to be located near the Wabash tracks.

Russellville, Ark.—A. Bemard, S. J. Smallwood R. L. Harkey and others have incorporated the Merchants' Light & Cold Storage Company of this city with a capital of $50,000. It is proposed to operate an electric light, power, storage plant, etc.

San Antonio, Tex.—It is reported that C. A. Ziker, vice-president of the Southern Ice & Cold Storage Company contemplates organizing a company to establish an electric light plant.

St. Louis, Mo.—The board of public improvements has appropriated $15,000 for an electric lighting plant at the City Insane Asylum.

Sturgeon, Mo.—The installation of an electric light plant is proposed in this city. J. W. Hulett, O. D. Gray and P. I. King have been appointed as a committee.

Yoe, Pa.—The Yoe Electric Light Company, with a capital of $5,000, has been incorporated

STREET RAILWAYS.

Bowling Green, O.—The Toledo & Bowling Green Traction Company, with a capital of $1,000,000, will erect a new consolidated power house at a cost of $200,000.

Clinton, Ind.—There is considerable discussion here of a proposed interurban line between this town and Paris, which it is thought will result in something tangible.

Delta, Col.—The board of county commissioners has granted an electric road franchise to W. B Stockham and Charles Pike.

Leola, S. D.—Farmers living in this vicinity have taken up the project of building an electric line between here and Aberdeen.

Lexington, Ky.—The Fayette Traction Company will build a railway from this city to Versailles.

Litchfield, Ill.—W. B. McKinley will erect a trolley line from here to Decatur.

New Haven, Conn.—The New York, New Haven & Hartford Railroad last week took over another trolley line, the Berkshire Street Railway, which runs from Great Barrington, Mass., to Cheshire, about 30 miles. It paid about $800,000 for the road. The bonds bear 3 per cent. for the first few years of their running and 3¾ afterward.

Rolfe, Ia.—The matter of the building of an electric road from here to Fonda is being considered.

Shelbyville, Tenn.—An electric line will be built between this city and Fayetteville.

Springfield, Ill.—The stockholders of the Springfield & Northeastern Interurban Company have voted to issue bonds to the amount of $700,000, for the construction of a power house for the line between this city and Bloomington. The power house will be built at Lincoln.

St. Charles, Mo.—Another new electric line is to be erected here.

Vinton, Ia.—A franchise has been granted to the Vinton & Belle Plaine Electric Interurban Railway Company.

Winona, Ind.—The Winona Interurban Railroad Company will erect a new power house at a cost of $600,000, to furnish power for the various electric lines it proposes building.

POWER PLANTS.

Allegan, Mich.—The Kalamazoo Valley Electric Company, which owns three large power houses on the Kalamazoo River, located at Otsego, Plainwell and this place, contemplates the expenditure of a large amount of money for the purpose of putting in more power plants in various parts of Western Michigan.

Birmingham, Ala.—The Tallapoosa Water Power & Electric Company is to be incorporated. Ausfeld & Chapman, contractors and engineers, are interested A plant to cost $500,000 is to be built.

Duluth, Minn.—The Great Northern Power Company, recently incorporated with a cash capital of $4,000,000, obtained through C. D. Barney & Co., and Tucker, Anthony & Co. will put up a plant near this city, on the St. Louis River, to develop 30,000 hp., to be raised eventually to 200,000. It is expected that the United States Steel Corporation will contract with it for electric motive power to run both the Duluth & Iron Range and the Duluth, Missabe & Northern.

Gering, Neb.—The construction of an $85,000 power plant on the North Platte River near here is proposed by G. L. Shumway, of Scott's Bluff.

Hamburg, Mich.—A large power plant is being built here. Ex-Senator Charles A. Ward, of Ann Arbor, is the promoter.

Pecos, N. M.—It is proposed to construct a large power plant on the Pecos River near the Pecos Forest Reserve to transmit electric power to Albuquerque, Santa Fe and Las Vegas. Joseph C. Bonner, of Toledo, O., is interested.

Sumter, S. C.—George E. Ladshaw will install a power plant here.

BIDS WANTED.

Columbus, O.—J. A. Taft, 307 New Hayden Building, is in the market for a good second hand 14 x 16 inch, or a 16 x 42 inch Corliss engine.

Johnson City, Tenn.—The Barton-Nuchols Hardware Company wants prices on electrical supplies.

Lyons, Ga.—J. B. Exum, of this place, is in the market for dynamos, engines and boilers.

Mullins, S. C.—J. B. Blackman, care of the Pee Dee Brick Company, of this city, wants to purchase a 50 hp. engine and 60 hp. boiler.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 15⅛@15¼c.; Lake 15¼@15⅜c.; casting, 14⅞@15c.

The annual meeting of the Lowell (Mass.) Electric Light Company will be held in Lowell February 1.

The Chicago Edison Company has declared the regular quarterly dividend of 2 per cent., payable February 1.

The executive committee of the Massachusetts Electric Companies has decided to issue hereafter quarterly statements of gross and net earnings.

There is no basis for the rumor that the next dividend on General Electric will place the stock on a 10 per cent. basis. The regular 2 per cent. dividend will be declared.

James F. Shaw has filed a petition in the Massachusetts Senate for the incorporation of the Boston & Providence Street Railway Company with a capital of $1,500,000.

The $10,000,000 bond issue for the purpose of constructing the proposed Cincinnati, Toledo & Columbus Traction Line, has already been subscribed and the road is now assured.

The Western Telephone & Telegraph Company has declared a semi-annual dividend of 2½ per cent. on the preferred stock, payable February 1. This is the same rate as was declared last August.

The National Carbon Company has declared the regular quarterly dividend of 1¾ per cent. on its preferred stock, payable February 15. Books close February 4 and reopen February 28.

It is now said that the Keystone Telephone Company of Philadelphia has made no deal for the sale of its underground conduits, and that the development of the company on independent lines is to be expected.

It is reported that the Brooklyn Rapid Transit Company will issue $10,000,000 bonds in the near future, the proceeds from the sale of which will be expended on improvements during the current year.

Kuhn, Loeb & Co. of New York have purchased from the Western Union Telegraph Company $3,000,000 of its funding and real estate and mortgage bonds. This is part of an issue of $20,000,000. The bonds will bear 4½ per cent. interest.

Negotiations for an indeterminate franchise along the lines suggested by August Belmont will probably be opened by the new traction syndicate with the city of Chicago as soon as a majority of the Chicago City Company's stock has been deposited with the Illinois Trust & Savings Bank.

The stockholders of the Butte Electric & Power Company, a New Jersey Corporation, at a meeting held in Newark, voted to increase the capital stock from $2,500,000 to $3,000,000. The present capital stock is divided into $1,000,000 of preferred ond $1,500,000 of common stock. The new stock will be used in the purchase of additional plants at Butte, Mont. It is also probable that an issue of bonds will be made in addition to the stock issue for the same object.

Interborough in the course of its movements on the Curb in this city on Monday sold up to 202⅜. Later it dropped abruptly to 195¾, and the final sale was made at that price. Shortly after the opening the stock was offered as low as 194, but that was taken and no sale was made below that figure. Transactions in the stock amounted to about 7,500 shares, or less than the total for the two hours of trading on Saturday, when the price rose from 187 to 199.

EDITORIAL NOTES.

Wednesday's Blizzard.

The snow storm which began Tuesday night, January 24, and kept up all through Wednesday tested the transportation facilities in Greater New York as nothing else could have done.

The storm itself lasted scarcely twenty hours, but during that time 9½ inches of snow fell. To make matters worse, the thermometer stood most of the time at 10 degrees above zero and a 40-mile-an-hour wind prevailed.

With conditions such as these, the majority of the surface cars in the Borough of Manhattan were, in a very short time, unable to run, due to the slot filling with snow of the consistency of granulated sugar.

In Brooklyn, the cars being equipped with the overhead trolley, managed to keep running in a desultory sort of way.

Owing to the dryness of the snow the trains on the elevated roads were not delayed nearly as much as was to have been expected. It is true pyrotechnical displays between the third-rail and the shoes on the cars were constantly in evidence, but nevertheless the road continued to be operated and passengers were carried.

But it was the new subway that was really in demand during and just after the blizzard. Tremendous crowds poured into and out of the subway stations all along the line. Ticket men and trainmen went about without overcoats and it was hard to realize, owing to the warmth of cars and stations, that Siberian weather was being experienced a few feet overhead.

But in this emergency the subway solved the transportation problem and carried the majority of passengers, and that without delay or accident of any kind.

When the rest of the tunnels are completed, not only in Manhattan Borough but to Brooklyn and New Jersey, which is to be hoped will be soon, then Greater New York will be prepared for any kind of weather.

* * *

A Forty-Knot Cruiser.

In the issue of ELECTRICITY of April 27, 1898, we referred at considerable length to a so-called electrically-propelled cruiser which had then recently been brought out. The inventor, Mr. Richard B. Painton, claimed that by making use of ten to sixteen independent propellors a ship could be driven through the water at the rate of forty knots an hour.

In this connection it is interesting to note that a bill has just been introduced in the House of Representatives at Washington, having for its object the authorizing of the Secretary of the Navy to make a contract with Mr. Painton for not only a cruiser but a torpedo boat as well. The former would cost, approximately, $2,000,000 and the latter $500,000.

If the bill is passed and the ships built the motive power will be electricity generated by dynamos operated by steam turbines. Electric motors will be made use of exclusively.

The sum of money which it is desired to have appropriated seems a large amount to be expended more or less experimentally, but if when completed such a cruiser would accomplish what is claimed for it in the way of speed, the people's money will not have been spent uselessly.

* * *

Rapid Relief in Storm Centers Through Electricity.

The test of efficacy which must be applied to electrical apparatus is the test of serviceability under the stress of adverse conditions; conditions which for a time at least plunge or threaten to plunge a large city into a state of chaos. Recounting the advantages of a purely superficial character which arise, due to the invulnerability of electrical devices to such influences, is too light a reference to the real truth. There are certain facts worthy of presentation in connection with electrical service of any kind at the present hour which lie deeper down than the mere mention of their operativeness during storms. It is easy to realize that the greatest stability has been reached in the equipment and construction of our best known institutions of that kind. To the public, changes which are and have been taking place have merely appealed to them in a negative sense.

Poles once above the ground have disappeared; electric lights which once flickered and frequently went out now burn brightly; electric cars reach their destination with certainty, and the telephone, no longer a nerve-racking experiment, has entered the field of successful and substantial engineering accomplishments. There is something to be said of all these beside the mere fact that they work. Surely the steady throb of an engine and the hiss of a dynamo are indications of greater progress than the tympanum alone can appreciate. The substantiality of electrical devices today is the surest proof of a scientific and technical grasp of existing conditions by electrical engineers.

The readiness with which a great city like New York recovers from the grip of an arctic storm of almost unprecedented severity is in reality a triumph of engineering. How dependent the average citizen is upon the inventor can only be understood with emphasis when his devices absolutely fail. In the city all great financial transactions require the ticker and the telephone—and outside of it the telegraph holds sway. In a great bee-hive of industry like New York, the cessation of transportation facilities means the stagnation of commerce and manufacturing. The intensity of city life—its very "strenuousness"—is based upon the use of these most modern methods of travel and education.

The great arteries, through which the animating force of great cities is transmitted, are the trolley, telephone and telegraph lines. If these hold good during great meteorological changes their influence is hardly felt. What testimonial to the technical excellence of such necessities is heard of after storms and floods have passed away? Huge snow banks may impede traffic, and in addition the trolley lines unfortunately crossing their path; but this does not mean that the service has broken down.

It does not mean that the system is poor, it is no more a criticism against an electric system than if an avalanche swept away wires and conduits or a tornado destroyed the rolling stock of steam roads. The point of greatest interest is the rapid recovery of a great city from the thraldom of ice and snow. How this is accomplished and the degree of effectiveness it represents are one of the newest and most interesting propositions of city life. A well-known editor of a great daily paper once said "Take away the telegraph and telephone and what will civilization have left?" The military sages have understood this fact, and in warfare the isolation of a town or city is practically electrical isolation. When severe storms beat upon the telegraph and telephone systems ineffectually—winds of 50 and 60 miles an hour—it must excite admiration for the solidity attached to such delicate equipments. It is only by this solidity that municipal paralysis is prevented and we are able to enjoy, uninterruptedly, the comforts or luxuries which are our birthright. If a great storm brings no other lesson it at least shows to advantage the skill and knowledge of American electricians. It also proves the proposition that whatever reward an inventor may or may not get, he at least is among the greatest of public benefactors, and it is his gifts which are most valued when nature is at her worst.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

The threatened strike of the employes of the Interborough Rapid Transit Company of this city has been averted. The company has granted practically all the union demands. Several discharged employes will be reinstated, motormen will be allowed 15 minutes' rest at the end of each trip and more safety signals will be placed in the subway.

The inauguration of three-cent fares on the Cleveland Street Railway has proved a failure. The three-cent cars which were plainly placarded were but poorly patronized.

The Electrochemical Society and the New York Academy of Sciences has bestowed the name moissanite on the carbon silicide in the form of six-sided crystals found in the residue from dissolving the iron meteorite from Canon Diablo, Arizona. The name was given in honor of Dr. Henri Moissan, member of the Institute of France, who has added to his many discoveries of carbides by means of the electric furnace that of the new silicide in the meteor. The newly discovered silicide is harder than any known substance, except the diamond.

On January 26, the day after the storm, the underground road in the Borough of Manhattan carried 411,000 passengers. The increase was due to the fact that few, if any, of the principal surface lines were running.

George Baker of Traverse City, Mich., has invented a water-wheel which is a combination of turbine and horizontal, using both perpendicular overshot systems. It is especially adapted to use in small streams, giving a high horse power with a low head of water. It is claimed by the inventor that farmers will be able to light buildings with electricity and secure all the needed power for stationary machinery.

Messages were lately telegraphed and telephoned simultaneously on the telegraphone between Peoria and Chicago, Ill., and the experiment was pronounced an entire success. The inventor of the device is H. C. Rugh, who holds patents in twelve different countries.

The German Emperor, according to the "Electrical Engineer," London, is exceedingly jealous about anything that concerns Potsdam, for it was there that his "never-to-be-forgotten" ancestor the great Frederick was born. Lately it has become recognized as imperative that electric traction shall supersede the old horse cars, but in the middle of the road connecting the town with the railway station are the remains of the old linden tree around which the people were wont to attend upon Frederick with petitions. This would have to be removed, and though it is but a remnant of decayed timber, the Kaiser insists that sentiment shall prevail over utility. His Majesty objects to the use of the overhead system on this road and suggests that the best plan would be to use an alternative route, which should also be well away from the palace. It is estimated that an additional expenditure of over $300,000 would be entailed, but "the Kaiser promises that the State shall bear half." As the Potsdam coffers are not overloaded, even a moiety of this sum represents a substantial tax, and a number of the inhabitants consider hero-worship rather dear at the price; but it looks as though the town will have to acquiesce—or, at any rate, pay.

DIRECT CURRENT VERSUS ALTERNATING CURRENT DISTRIBUTION.*

BY O. M. RAU.

With the recent policy of consolidation where railway and lighting properties are under the same management, the best method of distribution for the lighting system has become a question of considerable importance.

The generally adopted method of operating extensive railway systems is by means of high tension A. C. main stations and rotary converters. This makes available the prime source of power from the high tension main stations for the lighting system, which must be converted suitably for the various systems of distribution installed, which generally consists of a series alternating arc lighting system for street lighting, a 110-220 volt Edison direct current system for the thickly populated districts and a 2,300 volt alternating current transformed to 110-220 volts for the suburbs.

With this variety of distributing systems a very complicated assortment of secondary apparatus is necessary, making the original investment very high and creating a maintenance account considerably above that which would prevail if the system were more unified.

The one problem to this end, which seems most difficult to solve, has been the abandoning of the old standby Edison system. It is my opinion that the 25 cycle alternating current apparatus would never have reached the development that it has at the present state of the art had the consideration of abandoning the direct current, and displacing it with alternating current, received the study that the latter system warrants, as a method of distributing electrical energy in our large cities.

With the installation of 60 cycle instead of 25 cycle high tension generators in the main power house, the flexibility of these plants is greatly increased, and their adaptation to lighting purposes would be a very inexpensive proposition.

There has been considerable controversy as to the stability of a 60 cycle rotary compared to that of a 25 cycle rotary. The argument had considerable weight before the advent of the turbine, but by having a rotating instead of a reciprocating engine for the prime source of power, the stability of a 60 cycle rotary is equally as reliable as that of a 25 cycle rotary, and therefore the 60 cycle current becomes just as suitable for direct current railway systems as the 25 cycle, and naturally is directly applicable for lighting and power service, and becomes readily convertible by static transformers for the various distributing systems required by a lighting installation. Particularly is this favorable for the central or business districts of a city as the installation of static transformer sub-stations is inexpensive compared with the large investment of copper or the frequent location of rotary stations with their attendant losses in efficiency and expense of maintenance.

It will therefore be interesting to see the relative advantages between an extensive installation on these lines for system such as is in use in the larger cities of this country.

As stated before, there are no advantages in a 25 cycle over a 60 cycle system for the direct current railway output, therefore the costs and efficiencies for this part of the equipment will remain the same, as in both instances standard rotary converters would be required.

For the lighting and power systems the advantage would be that due to the difference in efficiency and cost of the necessary converter apparatus for the direct current system and frequency changes for the alternating current system, as against static transformers. The latter would eliminate the following disadvantages:

First—Two transformers for each kilowatt output, namely, from high tension to low tension alternating current through static transformers, and from low tension alternating current to direct current through rotary transformers.

Second—The installation of three kilowatts of apparatus for each kilowatt of output, namely, one kilowatt in main station generators, one kilowatt in static transformers, and one kilowatt in rotary transformers.

Third—The large investment in copper for feeders to economically distribute large quantities of copper.

Fourth.—The maintenance of two systems of distribution, as the direct current is not suited for the outlying suburban districts, and would, therefore, require alternating current to cover this portion of the territory.

The usual practice in operating a direct current system from high tension alternating power plant requires the installation of frequent sub-stations equipped with standard apparatus, consisting of necessary transformers, regulators and rotary converters. From this the current is distributed through the usual low tension switchboard, feeders, mains, etc., to the customer's premises.

For an alternating current system the current would be taken directly to static transformers, which would be placed at such locations as the concentration of load would indicate, and would be located at more frequent intervals than rotary sub-stations, thereby avoiding the extensive system of feeders, as the current would be taken directly from the low tension side of the transformers to the mains.

In comparing the efficiencies of an alternating current and direct current system the calculations were based on the assumption that the static transformers were to be located at the same points as rotary sub-stations and in units equivalent to the direct current rotary converters and cut in and out of use similarly to rotary apparatus as the load increased or diminished, using the usual system of feeders as employed on a direct current system to distribute the load to the mains. These calculations gave the efficiencies of the alternating current system installed as above described and of a standard rotary sub-station system, for various loads from a full load to a quarter load, as follows:

Full load A. C. system, 21.4 per cent; full load D. C. system, 27.6 per cent.

Three-quarter load A. C. system, 17.2 per cent.; three-quarter load D. C. system, 23.4 per cent.

One-half load A.C. system, 13 per cent.; one-half load D. C. system, 19.7 per cent.

One-quarter load A. C. system, 8 per cent.; one-quarter load D. C. system, 17.1 per cent.

These efficiencies are taken from actual tests, or guarantees from manufacturers. The losses on the low tension feeder system were in either case assumed to be equal, although if the static transformers for sub-stations were located more frequently (as they could be readily placed in basements of large buildings) the losses on feeders could be practically eliminated.

From these figures it leaves no doubt as to which is the most efficient system, as under any condition of load the alternating current system will operate with from 6 to 9 per cent. less loss than a direct current system.

The next important question is the comparative cost of the installation. The calculations were based on a station having a capacity of 15,000 kilowatt full load output. This showed a saving on the cost of apparatus and buildings for sub-stations alone of $130,000, which is entirely due to the smaller space required for static transformers, and the difference in cost between the necessary converting apparatus from alternating to direct current as compared with the cost of static transformers for the alternating system.

---

* Paper read at the 13th annual convention of the Northwestern Electrical Association, held at Milwaukee, Wis., Jan. 18-20, 1905.

We, therefore, have as an increased economy up to the customers' premises on the alternating current system the saving due to the difference in losses, the saving on interest due to the smaller investment and the saving on depreciation due to simple installations, which amounted, on the installation referred to, to somewhat more than $75,000 per year, the output of the previous year being used on which to calculate the value of the losses.

So far the investigation from a financial point of view leaves no question as to which system of distribution to adopt.

The next question to receive consideration is the relative commercial value of the two currents, and it is on this question that the difficulty is encountered of persuading the interests controlling the large direct current systems to change to an alternating current system.

After a most exhaustive investigation of this part of the question there was found, in a city of some 600,000 inhabitants, no installation which is now served by a direct current system, which could not be served equally as well, if not better, by an alternating current system.

As to purely electric lighting service the alternating current is more suitable than the direct current, giving a greater variety of uses, as well as a more effective means of distributing light. The incandescent lamp is equally effective on both systems, so also the arc lamp, while the Nernst lamp adds materially to the advantages of alternating current lighting, and the ability to do decorative lighting by means of low voltage lamps through the introduction of transformers opens a field of economy in this class of work which could not be attempted with direct current.

For ordinary power work the alternating current motor is superior to the direct current motor, as the abolishing of brushes is a decided advantage where a large number of small motors are in use. In looking up the trouble calls from power customers it was found that fully 75 per cent. were due to brush or commutator trouble.

The greatest difficulty to overcome is the variable speed motor customer, but as this class of service is limited to the larger users of power, they could be readily accommodated by the installation of motor generator sets for each individual case.

The operation of elevators is also difficult to take care of with the alternating current motor, but with the development of the single-phase railway motor a suitable elevator motor cannot be far off, and all that is needed is the creation of a demand for apparatus of this class, when, no doubt, our associate members will be ready to supply the demand.

In conclusion it might be stated that on the favorable showing made by this investigation, a change has been made from a direct current three-wire Edison system to an alternating current, 60-cyle, single-phase system in the city of Racine which is an active manufacturing town and has a population of 30,000 inhabitants, and where every practical class of service was met that could be covered by a central station system.

◆

HIGH-TENSION SWITCHGEAR.*

BY L. ANDREWS, M.I.E.E.

(Concluded from page 51.)

We have always felt that no discriminating circuit-breaker that failed to comply with the following conditions could be considered a satisfactory protective device:

(a) An alternating current discriminating cut-out must not be released by a low resistance short-circuit beyond the cut-out.

(b) It must not be released by a current supplied to a highly-inductive load beyond the cut-out.

(c) It must not fail to be released should the prime mover driving the generator controlled be pulled up by a hot bearing or similar failure.

(d) It must not fail to be released should the field of the generator controlled break down.

(e) It must not fail to be released by a very heavy reverse current, even should the pressure across the bus-bars drop to as low as 20 per cent. of normal pressure.

There are other conditions equally important, but it will generally be found that a device that complies with the foregoing is also capable of dealing with other conditions.

Fig. 6 is a simple differential solenoid, the two windings of which are connected in parallel across any low tension source of supply, A—B, excited from the main bus-bars. These windings are parallel on one side through a small equalizer, upon which is wound one turn of the cable between the generator to be controlled and the main bus-bars. So long as there is no current in this series turn the current from the low tension source of supply divides equally between the bottom and the top winding of the differential solenoid, and its core is in consequence neither pulled up or down, but is held down by gravity. A generating current in the series turn will destroy the balancing effect of the equalizer, causing more current to flow through the lower coil and less through the upper coil of the differential solenoid, with the result that the core will be held down magnetically as well as by gravity. A reversal of the series current will induce more current to flow through the upper coil and less through the lower one, thus lifting the core and releasing the cut-out.

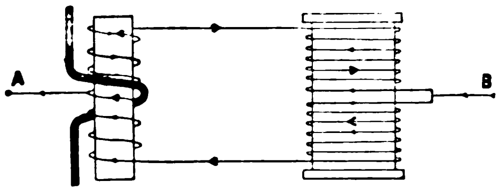

Fig. 6.

Here we have only two influences to consider. In the first place we have a simple series transformer, the secondary of which is closed through two solenoids connected in series; and, in the second place, we have two parallel circuits of equal ohmic and inductive resistance connected across a source of potential supply. When the induced secondary potential and the applied potential are in phase with each other, they will oppose each other in the upper winding of the differential solenoid and reinforce each other in the lower winding. When the respective potentials are 180 degs. out of phase with each other they will be in opposite directions in the lower and in the same direction in the upper winding.

The worst condition to be dealt with is that of a 90 degs. displacement of phase between the two potentials. In this case the effect upon the differential solenoid will be the same as if both coils were connected in series with the common return of a two-phase system. Two independent currents lagging 90 degs. behind each other will flow through both coils, and as they will be of the same value in each coil the coil will be neither pulled up nor down. This defect may obviously be corrected by inserting an inductive resistance in series with the potential supply A—B as suggested earlier in this paper. Another method of providing a cut-out that will take care of either a failing prime mover or a failing field is to use a double-barreled relay, consisting of two differential solenoids connected in parallel—a non-inductive resistance being inserted in series with one and a highly inductive resistance with the other. By this means the necessity of making adjustments in each case to determine the best mean point for both conditions, is entirely avoided.

---

*Abstract of paper read at the meeting of the Manchester Section of the British Institution of Electrical Engineers, December 13, 1904.

We sometimes find that engineers are a little uncertain as to whether discriminating cut-outs or reverse current cut-outs should be used in certain positions. The following rule appears to apply to all cases:

"Where current is fed into bus-bars from a number of sources of supply connected in parallel discriminating cut-outs only should be used. Where current leaves bus-bars to supply a number of feeders, transformers, motors or distributors, excess current cut-outs only should be used."

We are often asked whether a discriminating cut-out should operate instantaneously or whether it should possess some time element. On the whole the advantages appear to be on the side of instantaneous action. It is certainly desirable that a generator breaking down should be cut out of circuit with as little loss of time as possible, and with a reverse current of something less than the full-load current.

Apparently the only argument in favor of a time-limit attachment is that a reverse current device without time element is liable to be tripped by the rush of synchronizing current from one generator to another when machines are being paralleled.

The simplest way of dealing with this difficulty appears to be either to switch off the shunt windings of the discriminating device at the moment of paralleling, thus rendering the device entirely inoperative or to greatly reduce the pressure across this winding when paralleling, thereby correspondingly increasing the reverse current required to operate the device.

DISCRIMINATING RELAYS AND CUT-OUTS.*

BY M. B. FIELD.

It is difficult to account for the mystery which is usually supposed to surround the design and operation of discriminating relays and cut-outs for alternating current circuits. For example, it is not infrequently stated that one type of relay (what is stated here with reference to relays is equally applicable to cut-outs) works well under certain conditions and fails to operate under other conditions; while a second type will perform its functions in the latter case, but breaks down in the former. Hence, a vague impression exists among many engineers that no relay (short of one possessing superhuman intelligence) can be expected to discriminate correctly in every one of the multitudinous cases which may be presented to it, and answer unfalteringly the vital question, "Must the circuit be opened or not?" That this impression, if it exists, is a mistaken one will here be demonstrated. The criterion as to whether a discriminating relay should operate under any given condition is a perfectly definite and simple one, as we shall see later on. In the writer's opinion much of the difficulty of the subject is solely due to the unfortunate designation "reverse-current" relay. This is undoubtedly a misnomer. What is exactly meant by reverse-current when dealing with alternating current circuits? In connection with continuous current circuits the phrase is a perfectly legitimate one, and presents immediately a definite conception. If we adopt the usual convention as to the direction of flow of a current we can consider a "forward current" as one flowing in the direction in which the EMF. acts, and a current flowing in the contrary direction as a "reverse current." Or we may adopt the convention that a current flowing into the "A" terminal of a given piece of apparatus inserted in the circuit (e.g., a relay), and out of the "B" terminal, is a forward current, apart from all consideration of the direction of the EMF. In this sense a polarized relay can discriminate between a forward and reverse current without reference to the EMF. at all. Such a polarized relay is undoubtedly the correct principle to adopt in the case of continuous current circuits, since its action and adjustment is independent of all variations in the supply voltage. Thus, should an excessive reverse current occur which had the effect of reducing the supply EMF. to nearly zero value, the relay would still operate, while a forward current, however large, would be ineffective in this respect.

In the case of an alternating current circuit the matter must be approached in a different way altogether. A current which at every instant is flowing in the direction in which the generated EMF. acts is undoubtedly a "forward current," while a current which at every instant flows in the opposite direction is a "reverse current;" the first is in phase with the EMF., the secondis 180 degs. out of phase. This is all quite obvious, but what about the current lagging or leading by 90 degs.? During half of each cycle it is flowing in the same direction as the EMF.; during the other half cycle it is flowing in the opposite direction. Such a current is consequently neither a forward current nor a reverse current, and whatever its magnitude should not cause a so-called reverse current device to operate.

Now, let us consider a current which lags, say, a little more than 90 degs. behind the EMF. (Fig. 1). We have then flowing in the circuit two currents superimposed, viz., O A and O B; not figuratively, but actually and really, these two currents exist. Now O A is, as we have seen, neither a forward nor a reverse current—as far as the relay is concerned it is a nonentity; O B is then the only current we have to consider, and it will be noted that it is the power component of the current C. In Fig. 1, O B is at every instant flowing in the opposite direction to the EMF.; hence, although the current C flows in the circuit, the reverse current is not C but O B. Had C lagged behind the EMF. by an angle less than 90 degs. (Fig. 2) there would have been no reverse current, but a current of amplitude O B' flowing in the same direction as that in which the EMF. acts.

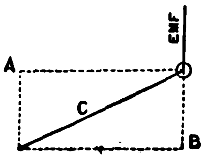

FIG. 1.

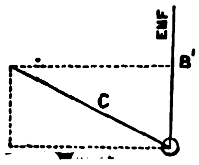

FIG. 2.

The criterion, therefore, which must alone decide the operation of a successful relay is: Is the power component of the current in the same direction or opposite direction at every instant to that in which the EMF. acts?

Having determined the specific condition or criterion which decides whether the ideal relay must operate or not, it is obvious that we have also determined the condition which must be made the controlling principle of the relay—in other words, the working principle of the relay must be so chosen that whenever this specific condition is absent, no matter what the other circumstances of the case may be, no tendency to operate is experienced by the relay. On the other hand, given the specific condition, viz., the existence of a reverse power component of the current, however small, a tendency to operate must be experienced by the relay. We do not say the relay must operate; it may be inconvenient to make it too sensitive, or it may be wished to introduce a time element, but we reiterate that if the current has a component representing reverse power, however small, a tendency to operate will be experienced by a properly designed relay, while a component representing forward power, though it may be large enough to destroy the relay, will not produce any tendency to actuate its mechanism.

---

*From the "Electrical Review." London.

In the past numerous relays have been designed, which, in given circumstances, have proven unsuccessful, and the reason for this has not been that they were too sensitive or not sensitive enough, that they were too sluggish, or not sufficiently sluggish, but simply that the underlying principle controlling their movements did not necessarily coincide with or involve the single criterion which alone must determine the action of the successful relay. Thus, whereas the two conditions (viz., that which actually controlled the relay mechanism, and that which theoretically alone should control it) in numerous cases were co-existent, they were not necessarily so, and instances arose when this was not the case; hence the failure of the relay.

The question therefore arises, how are we to enable the relay to judge whether the main current contains a reverse power component? Clearly we must provide the relay with a sample of both the main current and the supply EMF. (in this latter respect it differs radically from the continuous current device). These samples which must be produced in their correct phase relations, are usually obtained by the aid of current and potential transformers. We must then leave it entirely to the relay to discriminate.

If properly designed it will sift out the power from the wattless component of the current sample, compare this as regards direction with the sample of EMF. and make up its mind accordingly.

How, then, must the relay be constructed to enable it to achieve this result?

A simple differential solenoid is manifestly wrong, since a current, whether forward, reverse or wattless, if large enough to swamp the effect of the shunt winding, would operate the relay. Such was pointed out by Mr. Leonard Andrews in his recent interesting paper on the subject, read before the Manchester Section of the Institution of Electrical Engineers.

An obvious way to meet the case is by the use of a wattmeter relay, pure and simple, since reverse current (as previously defined) cannot exist without reverse power. Clearly such a device will tend to operate with the smallest amount of reverse power and will exhibit no such tendency with any amount of forward power. If, therefore, it can be made sufficiently sensitive to operate with the smallest amount of reverse power which constitutes a dangerous condition, it is evident that it will theoretically form an ideal relay. This principle was also mentioned by Mr. Andrews in the paper referred to as first suggested many years ago by Dr. S. P. Thompson.

The necessity for a sensitive device becomes at once obvious when we consider that, although the actual current flowing be large, the power component of the same may be very small. This is the real difficulty experienced hitherto with compound differential devices. It is manifestly incorrect to introduce, for this reason, spurious phase differences, as suggested by Mr. Andrews. This is merely overcoming one trouble, and introducing the possibility of another—inoculating the vaccine in order to prevent smallpox. If we introduce spurious phase differences between the samples of EMF. and current, we shall find that with certain defined phase relations between main current and EMF., the relay will operate when it should not, and fail to operate when it should. True, the conditions involving these particular phase relations may rarely be met with in practice; they are, nevertheless, real and possible, and such a relay depends for its working principle upon a condition other than the criterion which should determine its action. Having shortly dealt with wattmeter relays, we may touch upon compound differential devices. Several forms of these have been suggested.

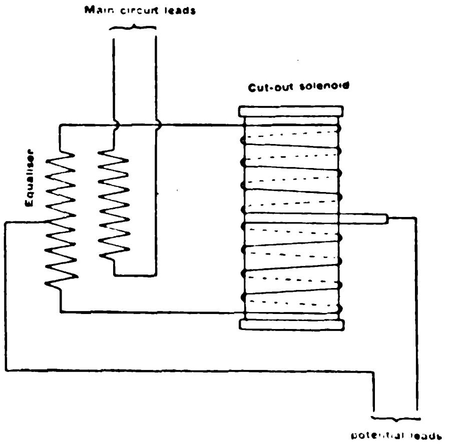

FIG. 3.

The principle consists in two solenoids pulling a single armature in opposite directions. In the one solenoid the effects of the samples of current and EMF. are added, in the other, subtracted. Imagine an armature symmetrically placed between the two solenoids, or two halves of a single solenoid, the magnetic circuit being such that the pull due to either solenoid is proportional to the square of the ampere turns. The resultant pull at every instant will be proportional to$(v + c)^2 - (v - c)^2$, or 4 v c, where v and c represent the samples of EMF. and current respectively. The foregoing expression obviously represents watts, that is, the mean pull on armature is proportional to the average watts of the circuit, and will, therefore, be in the one direction in the case of reverse power, in the opposite direction in the case of forward power. We have introduced this—a purely hypothetical and ideal relay—on account of its similarity with the devices suggested by Mr Andrews.

In the device shown in Fig. 3, which is advocated by Mr. Andrews, the current in the top half of the solenoid corresponds to the difference (v — c), and that in the lower portion to (v + c). It is obvious that there is as much need for delicacy in this as in any other type. Sensitiveness, however, is not compatible with the particular design chosen, hence the reason for introducing spurious phase differences, which are wholly undesirable for reasons already pointed out.

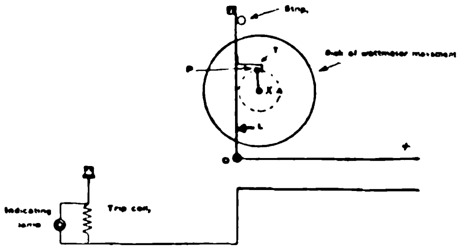

FIG. 4.

The relays will operate with any reverse power down to 10 per cent. of the full load of the circuit. This is found sufficiently sensitive to protect the average generator if the field circuit be opened—the severest test of a reverse-power indicator. A more sensitive device is not to be recommended. These relays can be made with and without time element. Fig. 4 shows diagrammatically the action of the relay. A weighted contact lever, L, pivoted at O, stands vertically. The wattmeter movement rotates about the axis, X (at right angles to paper), in a counter-clockwise direction with reverse power, and tends to rotate in a clockwise direction with forward power. Thus, the arm is posively held upright by the pin, P, in the wattmeter disk engaging in the projection, T, of the contact lever, as long as the transmission of power is in the forward direction. On a reversal of power the wattmeter rotates in the counter-clockwise direction, and the pin P impinging against the lever causes it to overbalance and fall into the horizontal position, thereby establishing the trip coil and indicator lamp circuits.

Another device is a polarized reverse current relay for direct current circuits. In this the serious disadvantage is absent under which all relays labor which have shunt and series coils combined differentially, viz., that the main current at which the device operates is largely affected by variations in the EMF. supplying the shunt winding. Further, it is found that many such differential devices will operate with a forward current if sufficiently large to swamp the effect of the shunt winding. For example, a partial short-circuit which momentarily causes a drop in the EMF. frequently causes so-called reverse current devices of the differential type to operate.

This relay is independent of the EMF. as regards its action and adjustment; and, if provision be made for supplying the trip coils from a separate source, the action is as certain, though the EMF. drop to zero, as if no variation in it occurred.

Where a separate source is not available for the trip coils, it is best to design the latter to operate with certainty at one-third normal bus-bar volts, and to withstand the application for five minutes of the full normal supply voltage. Fig. 5 shows diagrammatically the connections of this relay.

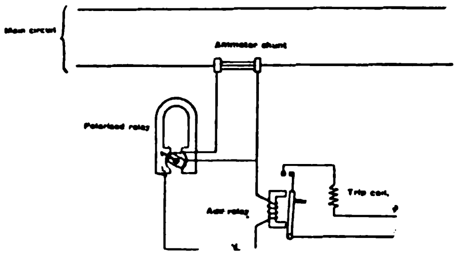

FIG. 5.

◆

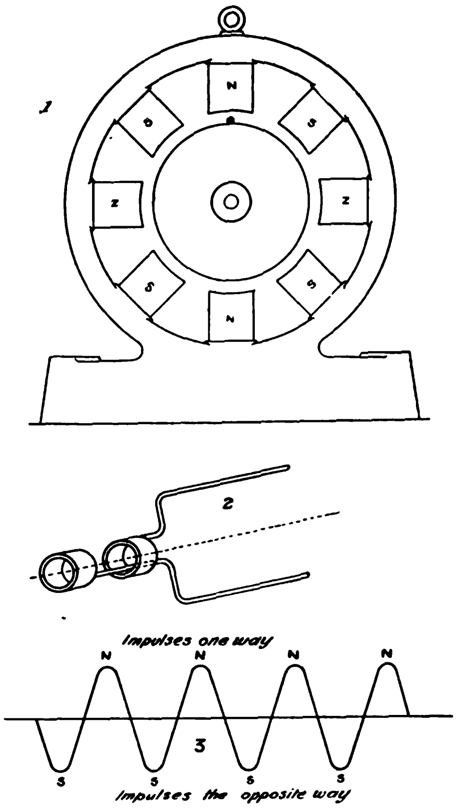
ELECTRICITY LEAFLETS.

BY NEWTON HARRISON, E. E.

THE DYNAMO.

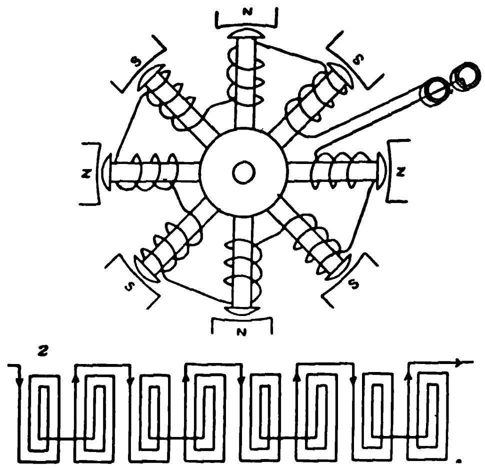
Kinds of Alternators.—There are several varieties of alternating current dynamos, distinguished from each other by an interesting peculiarity called "phase." To enumerate, there is the single phase, two phase and three phase dynamo. The meaning of phase may be readily understood with reference to the character of the currents they individually produce; and to accomplish this it is necessary to represent these differences partly by diagram.

The Single Phase Dynamo.—A wire on the armature of an alternator rotates past a series of poles of different polarities. It passes a north pole, then a south pole, a north pole and a south pole, and so on, as it continues its rotations. Every north pole it passes produces an impulse in the same direction; that is, all one way, and every south pole it passes produces an impulse in the opposite direction. Thus, the impulses of current due to the north poles are all in one direction and the impulses of current due to the south poles are all in the opposite direction. This idea is represented by a series of curves placed over or under a line. All the curves or waves over the line can be regarded as impulses due to north poles and those under the line as impulses due to south poles. Therefore a diagram of this character adequately represents in each two curves, one above and one below, the increase and decrease of the EMF., as the conductor sweeps past a north pole; the particular instant at which no EMF. is generated just as the conductor has emerged from the lines of force of the north pole and is about to enter those of the south pole; then the rise and fall of the EMF. due to the south pole with a return to practically the same conditions as the cycle is about to be repeated. Each pole is capable of producing one wave of EMF. in a conductor, and in consequence it is customary and necessary to depict this process of EMF. development by a curve as described. The name given to a curve of this character by mathematicians and so called by electricians is "the sine wave." It corresponds so closely to this curve that many of the most valuable formulas in use for the calculation and design of alternating current machinery have been obtained through this fortunate coincidence.



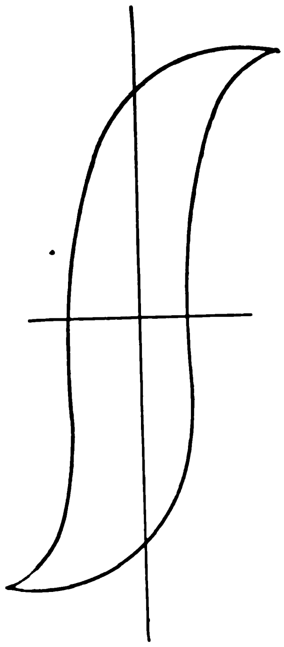
1—Conductor on Armature of 8-poled Alternator, Producing 4 Complete Alternations per Revolution. 2—End Connections to Collector Rings. 3—Wave of Alternating EMF.

Connections of an Alternator Armature.—A great many impulses occur in the winding on the armature of an alternator every time the conductors pass each pole. It has been necessary to devise a winding which would throw all similarly moving currents in one direction and thus avoid opposition between them. This is readily done by laying flat coils on the armature each around a projecting core and connecting their ends together, the outside terminals of adjacent coils and the inside terminals of those next adjacent, and so on, until the two final ends are connected respectively to collector rings, from which by means of brushes an impulse is collected as the coils on the armature pass a pole piece.



1—Radial Poled Alternator, Showing Armature Winding. 2—Connections of Alternator Armature Coils.

Hysteresis.—The iron core of the armature is magnetized first one way and then another, whether it belong to an alternator or a direct current dynamo. The effect of this is to consume power which manifests itself as heat. It makes no difference whether the iron have the highest magnetic conductivity or not this phenomenon always makes its appearance when iron is magnetized and demagnetized. The reason why power is consumed is as follows: When a bar of iron is magnetized by means of a coil carrying a current and the ampere turns or magneto-motive force is great enough to saturate it, the molecules of iron assume a certain polarized position. If an equal and opposite magneto-motive is applied by means of the coil the iron *will not* return to its normal condition; it will require extra magnetizing force to accomplish this, and if the process is continued until the iron is magnetized as highly in the opposite direction (with reverse poles) as before and then brought back to where it started from, it will be found that a considerable amount of power has been absorbed. A process of this kind is called a cycle of magnetization, and although it merely consists of the magnetization and reverse magnetization of iron with a final return to the starting point, yet each instance is an opportunity for power to be absorbed, which increases as the degree of magnetism to which the iron is subjected increases and also as the rapidity and frequency with which such operations are conducted per second. If a cubic foot of soft iron is put through such a process, according to a noted authority, when magnetized up to 60,000 lines of force per square inch, it will absorb 10 foot pounds of energy. If the process is carried on at the rate of 100 times a second, 1,000 foot pounds of energy are absorbed. It is easy to estimate that each minute would represent a power consumption of 60,000 foot pounds or nearly 2 hp. at this rate of change. All armature cores, therefore, must be calculated with respect to such a dissipation of energy and it is necessary to obtain figures which will enable such calculations to be carried out. Before presenting the formula discovered by Steinmetz, upon which all calculations of hysteresis (the name given to this property of iron) are based, it is evident that a heavily magnetized piece of iron, unless slowly magnetized and demagnetized, would develop a great deal of hysteresis, as well as a piece of iron moderately magnetized but subjected to a very rapid series of such changes. When alternating currents are used for this purpose, therefore, the iron must not be heavily magnetized and the same is true for the armatures of both direct and alternating current dynamos.



Hysteresis Curve. Showing Nne Complete Cycle of Magnetization.

The Steinmetz Formula.—The formula is a little difficult at first sight to those unaccustomed to the handling of symbolic forms, but the table will supply any deficiencies in this respect. In the formula a constant is multiplied by the lines of force per square centimeter, bearing the exponent 1.6, or the power consumed in one magnetic cycle for one cubic centimeter of iron is

Power consumed = .002 × (lines of force per square centimeter) $^{1.6}$,

in which .002 is called the hysteretic constant, which averages up for all samples of pure iron as shown:

Wrought-iron—hysteretic constant. .0017
Cast-steel—hysteretic constant.... .0025

The above formula reduced to symbols would appear as follows for one cubic centimeter of iron :

$$W = .002\, B^{1.6},$$

where W = ergs,
B = lines of force per square centimeter.

The value of an erg is best understood by those most familiar with the English system of units with reference to a foot pound. A foot pound equals 13,350,000 ergs. In the following table, in which the lines of force per square centimeter and per square inch are given, complete calculations are made by the Steinmetz formula for iron subjected to a series of increasing magnetizations :

FLEMING'S TABLE.

Lines of force per sq. cm.	Lines of force per sq. inch.	Ergs per cubic cm.
1,000	6,250	126
2,000	12,500	383
3,000	18,750	732
4,000	25,000	1,160
5,000	31,250	1,658
6,000	37,500	2,222
7,000	43,750	2,840
8,000	50,000	3,516
9,000	56,250	4,244
10,000	62,500	5,022

To use this table, the number of complete reversals of magnetism per second must be multiplied into the waste of power per cycle. For instance, if the frequency of an alternating current is 120 per second, a well known commercial rate for lighting circuits, the power wasted at 5,000 lines of force per square centimeter or 31,250 per square inch would be 3.21 foot pounds for a cubic foot of iron per complete reversal. For 120 complete reversals the power wasted would be 120 × 3.21 = 386 foot pounds.

In reference to the erg it may be stated that one pound = 445,000 dynes. A dyne, as previously explained, is the force required to impart to a gram a velocity of 1 centimeter per second. An erg is *the work* done in moving a body a distance of 1 centimeter against a force of 1 dyne. If a gram is moved against gravity a distance of 1 centimeter in 1 second 981 ergs of work are done. A pound is equal to 445,000 dynes because it weighs 453.59 grams, and the force of gravity equals 981 dynes per gram, that is to say, it takes 981 dynes to *impart* a velocity of 1 centimeter per second, or what is the same thing, a mass of 1 gram falls with a velocity of 981 centimeters per second; thus 453.59 × 981 = 445,000 dynes or 1 pound. If 1 pound is moved 1 foot it means a force of 445,000 dynes operating over a distance of 30 centimeters, the basis of estimate being .4 inch per centimeter and therefore 30 centimeters per foot. This calculation gives 445,000 × 30 = 13,350,000 ergs = 1 foot pound. If the last column of figures, which give the energy wasted in ergs, are given in the English system for 1 cubic foot of iron magnetized and demagnetized at the rate of 120 times a second, the following figures appear:

POWER WASTED PER CUBIC FOOT OF IRON AT 120 REVERSALS PER SECOND.

Lines of force per sq. inch	Lines of force per sq. cm.	Ergs per cu. cm.	Ergs per cu. ft.	Foot pounds per cubic foot.
6,250	1,000	120 x 126	40,824	29.32
12,500	2,000	" " 383	124,092	89.13
18,750	3,000	" " 732	237,168	178.00
25,000	4,000	" " 1160	375,840	270.00
31,250	5,000	" " 1658	537,192	386.00
37,500	6,000	" " 2222	719,928	517.06
43,750	7,000	" " 2840	900,160	661.00
50,000	8,000	" " 3516	1,139,184	818.17
56,250	9,000	" " 4244	1,375,056	987.6
62,500	10,000	" " 5022	1,627,128	1168.6

For armature cores this last table is very useful, also in those cases where the use of magnets on alternating current circuits are proposed. In alternating current work in general, whether single, two or three phase, of necessity dynamos, motors and transformers are in almost constant use; and these machines call for the application of the principles outlined so far as hysteresis is concerned, otherwise the internal development of heat within the iron would not only waste power but rapidly put a stop to the operation of such machines altogether.

Two and Three Phases.—If another current follows after the first impulse of an alternating current, but not so slowly that it differs in any respect from the first except in being an instant behind it, there are what are called two phases acting in the circuit. If three distinct currents follow each other in this manner, each an instant behind the other yet not so far behind that the three currents are not at some stage of growth or diminution at the same moment, there are three phases of current in the circuit or it represents a three-phase current.

Phases of this kind are produced in a very simple manner. The armature conductors are connected in such a way that in the case of a two or three-phase dynamo practically two or three distinct windings are in operation at once. In one winding the armature conductors, for instance, are one-third of the distance across a pole piece before the second winding is in operation. By this means the beginning of an impulse is one phase, which follows all the laws of an ordinary alternating current. The phase beginning when the first conductors have already been developing EMF. along one-third of the arc of the pole piece also rises to its full value and acts like the first phase. A third can follow in the same manner if the conductors are so arranged and connected to individual collector rings. Thus, instead of only one—two, three or more phases or currents can be developed by this method each distinct from the other, an instant behind it and serviceable for electric lighting and power transmission. Rotary converters found in power houses and sub-stations and nearly all self-starting alternating current motors are actuated by multiphase currents of either two or three phase.

THE ELECTRIC LIGHTING OF RAILWAY TRAINS.*

BY DR. ALFRED GRADENWITZ.

The system of electric lighting for trains described in the following was designed by Mr. Aichele, and is being brought out by the Aktien-Gesellschaft Brown, Boveri & Co., of Baden, Switzerland. In this system each car has a lighting plant of its own, consisting of a dynamo, a storage battery of some few cells, the regulation device, conductors and lamps. This will greatly increase the value of this system, which may be applied both to ordinary and express trains.

The dynamo, which is suspended in the middle of the truck, is a shunt machine of about 2 hp., being inclosed in a dust-tight cast-iron housing, and driven from one axle of the wagon by a belt. Its speed will thus, in any case, be proportional to the speed of the train. On the direction of the latter being reversed, its poles are changed automatically by shifting the brushes on the commutator. The storage battery includes 9 or 2 x 9 cells of a capacity of about 140 ampere-hours, corresponding to a lamp voltage of 18 or 36 volts.

The internal arrangement of the apparatus is shown in Fig. 1, the essential parts being the switching apparatus, C, and the regulating motor, R. The core of the apparatus is raised under the influence of the thin wire coil, a, connected to the terminals of the dynamo (see diagram of connections, Fig. 2) or of the apparatus, C, as soon as the train exceeds a speed of about 15 miles per hour, when the voltage at the terminals of the dynamo has reached the battery voltage. On the speed of the train being further increased, the battery will begin to be traversed by the charging current, passing through the second coil, b, of the switching apparatus, C, where it acts in the same way as the current in the coil, a, thus securing the connection between the dynamo and battery, which has been completed by the latter. At the same time, the regulation motor, R, will, however, be set working as soon as any machine current is developed, thus effecting an automatic adjustment of the shunt regulation resistance of the dynamo which controls the current supplied by the latter.

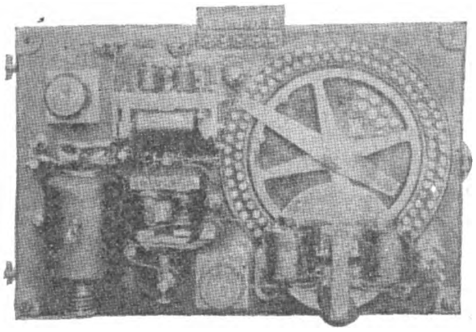


Fig. 1.
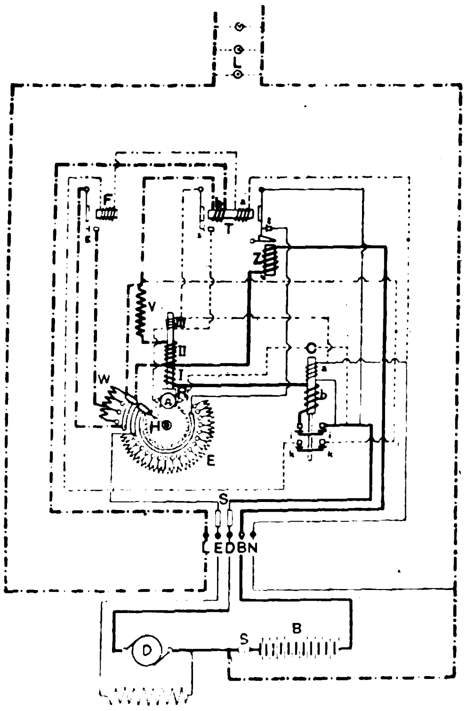
View of Regulation Apparatus.



—Diagram of Connections.

Fig. 2.

The motor magnets bear three independent exciting coils, marked I, II and III, respectively, in Fig. 2. As long as there are no lamps switched in, the coil I, traversed by the machine current, and III, which is applied to the battery terminals, will work simultaneously. If any lamps are thrown in, the coil III will be replaced by the coil II, which is traversed by the lighting current, so that the coils I and II now work simultaneously. Under the action of I, the lever, H, will be displaced so as to effect an increase, and under the action of II or III a diminution of the resistance in the exciting circuit of the dynamo. In both of these cases the lever, H, will thus be adjusted under the influence of two magnet coils of the regulation motor, acting in opposite rotary directions, so as to weaken the excitation of the dynamo as soon as the effect of the coil I traversed by the machine current becomes the stronger, on account, for instance, of an increase in the speed of the train. The lever, H, will then slide on the contacts of the shunt regulation resistance, E, as the speed of the train increases until the effect of the coil I corresponds accurately to the effect of the coils II or III, thus balancing the latter. If this state of equilibrium is attained, the motor will remain at rest until, on account, for instance, of a decrease in speed, the equilibrium of the two magnetizing coils of the motor is once more disturbed, when the motor, under the influence of the now prevailing coil II or III, turns the lever at the regulation resistance in an opposite direction, so as to increase the excitation of the dynamo, until the charging current traversing the coil I has returned to its previous value, thus re-establishing the equilibrium between the coils I and the antagonistic coil. By applying to the coil III the voltage of the battery there is thus obtained, in the first case, a regulation to constant intensity of the charging current, while, in the second case, by causing the lighting current to traverse the coil II the charging current is adjusted automatically in accordance with the lighting current, and at the same time the increase or decrease of the latter charging current is regulated by increasing or decreasing by steps the effect of the coil II (traversed by the lighting current) through a gradual modification of a resistance inserted in parallel.

During the stoppage of the train the connections between the dynamo and the battery, B, will be interrupted in the switching apparatus at i i (Fig. 2) when the lamps derive their current from the accumulator battery. The lever, H, has been placed during the preceding stoppage of the train owing to the action of the coils II (traversed by the lighting current) on the magnet of the electromotor, R, in the extreme position shown in Fig. 2, where the shunt regulation resistance and the coil II, inserted in the lighting circuit, as well as the shunt resistance V, before the lamps, are short-circuited. The lighting current will, therefore, in the beginning exert no magnetizing effect on the magnets of the electromotor, R, the lamps being applied to the battery terminals without any shunt resistance. The relay, T, having attracted its armature under the influence of the coil b, traversed by the lighting current, the contact will be completed, and the coil III will be out of action.

---

*From the "Electrical Engineer," London. Abstract.

On the train starting there will, as soon as the speed of the dynamo has become sufficiently increased, be a dynamo voltage equaling the voltage obtaining at the terminals of the battery, when the magnetizing effect of the coil a in the switching apparatus, C (which is being permanently applied to the terminals of the dynamo) suffices to lift the core of the apparatus, thus completing the connection between the dynamo and battery. The corresponding speed of the train is about 15 miles per hour. If the speed increases further, the tension at the terminals of the current generator will be augmented so that the battery is traversed by a charging current. This current, traversing the coil b of the switching apparatus, C, will act there in the same sense as the current in the coil a, that is to say, will secure the connection between the dynamo and battery that has been effected by this coil. In addition, the charging current will, however, traverse the magnetizing coil I of the electromagnet, turning the lever, H, from the extreme position to the nearest contact of the resistance, W. Instead of the short-circuit, part of the resistance, W, will now be placed in parallel to the coil II and the shunt resistance, V, when part of the lighting current traverses the coil II, which by its magnetizing effect balances the coil I traversed by the charging current, so that the lever is stopped in this position, until on account of the increasing speed of the train the effect of the machine current in the coil I becomes stronger. Then the lever, H, turns on to the second contact of the resistance, W, thus altering once more the distribution of the lighting current in the two parallel branches, so that the portion traversing the coil II and the shunt resistance, V, becomes greater and compensates for some moments the machine current traversing the coil I. The lever, H, will thus stop also in this second position for some moments, until the machine current becomes sufficient to move it on. During the increase of the charging current the lever, H, thus slides slowly over the various contacts of the resistance, W, while the portion connected in parallel to the coil II and the shunt resistance, V, increases continually until it becomes infinite, when the lever, H, has left the contacts of W. The shunt resistance connected to the lamp, and which consists of two parallel branches (coil II and shunt resistance V, on one side, and inserted portion of resistance, W, on the other) will thus be increased by steps which are adjusted automatically according to the actual intensity of the increasing charging current. The fall in voltage undergone by the fixed lighting current in this variable combined resistance thus corresponds at any moment to the increase in voltage at the battery terminals, due on one side to the disappearance of the discharging current, and on the other to the increase of the charging current. After the lever, H, has left the contacts of the resistance, W, on the train being further accelerated, the full amount of lighting current will traverse the coil II. The adjustment of the lever is effected by the simultaneous action of the two antagonistic coils, I and II, which are traversed by the machine and lighting current respectively. The zero position of the lever with the various speeds of the train corresponds always to an intensity of the charging current that bears a constant ratio to the intensity of the lighting current. The former will, therefore, undergo an alteration only in the case of the number of lamps inserted being altered, increasing and falling along with the lighting current.

In case the running speed decreases the electromagnet would, under the magnetizing influence of the constant lighting current, first move the lever, H, into positions corresponding to the smaller resistances in the shunt circuit of the dynamo, until the lever, H, has reached the contacts of the resistance, W, when the resistance is connected in parallel to the coil II, and the shunt resistance, V, so that the same process as on the starting of the train occurs in an inverse order, namely, a slow decrease of the charging current occurring by steps and being accompanied by a step-by-step diminution of the shunt resistance connected to the lamp. The charging current will have disappeared completely after the lever has returned to the first contact of W, when in the switching apparatus there will only be left the attracting effect of the coil a, which just suffices to maintain the core of the apparatus in the attracted position. The voltage of the dynamo has again reached the value with which the core of the switching apparatus, C, was attracted, thus being equal to the accumulator voltage. In the subsequent moment the dynamo voltage will, on account of the further decrease in the speed of the train, fall below the voltage of the accumulator battery, the core of the switching apparatus, C, dropping so as to discontinue the connection between the dynamo and battery. This decrease in the charging current and break in the connection between the dynamo and battery occurs without the luminous intensity being altered to any appreciable degree.

As soon as the perfect charge of the battery has been attained, the charging current disappears automatically, any switching made for its regulation occurring automatically and exerting no appreciable influence on the candle-power of the lamps. When all the lamps are switched off the lighting circuit the effect of the coil b on the core of the apparatus T will accordingly disappear. As the complete charge of the battery is reached the increase of voltage obtaining in the final charging condition at the accumulator terminals will be sufficient to produce the attraction of the core of the electromagnet, T, thus completing the contact, S, and discontinuing the effect of the coil III on the magnet of the electromotor. The latter, will, accordingly, under the action of the magnet coil I (which is traversed by the charging current) adjust the field excitation of the dynamos to smaller values until the charging current has disappeared completely. The present regulation system thus regulates the charge of the accumulator battery in the same way as in a stationary plant.

The Institute's Annual Dinner.

The preparations for the annual dinner of the American Institute of Electrical Engineers are being pushed actively and the affair promises to be a great success. It will be devoted, as already announced, to signalizing the triumphs of electric traction. President Lieb has appointed the following committee, which is already at work: Messrs. T. C. Martin, chairman; W. C. Gotshall, L. B. Stillwell, H. G. Stott, Calvin W. Rice, F. C. Bates, H. W. Blake, P. G. Gossler, E. B. Katte, C. W. Price, W. A. Pearson and W. L. Conwell. This committee has organized and sub-committees are at work on different features of the banquet. Some original and novel features will be included, and it is believed that the oratory will be unusually interesting. Messrs. Frank J. Sprague and Leo Daft are to speak for the Institute pioneers in this great field of electrical development. The banquet will be held in the grand ball-room of the

Waldorf Astoria on February 8, and it is expected that between 400 and 500 will be present, including many ladies. Tickets are $5 each, exclusive of wine. It may be mentioned that in addition to the features connected with the dinner itself, there will be exhibited, for the first time, the beautiful oil painting just presented by the British Institution of Electrical Engineers, as a souvenir of last year's visit, to the Institute, representing Dr. Gilbert making magnetic experiments before Queen Elizabeth. The bust of Prof. Ferraris, also presented to the Institute last year, will be exhibited in the Astor Gallery reception room.

Important Trolley Decision.

In the case of the Thomson-Houston Electric Company vs. Black River Traction Company, the Court of Appeals, sitting in New York, has rendered a decision sustaining the validity of the patent of Charles J. Van Depoele (deceased) for the well-known and almost universally used underrunning trailing-arm trolley.

American Institute Election.

Among those prominently mentioned in connection with the presidency of the American Institute of Electrical Engineers is Dr. S. S. Wheeler, at present serving as one of the Institute conferees on the Union Engineering Building joint board. Dr. Wheeler was one of the leaders 18 years ago in a movement to secure permanent quarters for the Institute.

Mr. Edison Recovering.

Mr. Thomas A. Edison is reported to be rapidly recovering from the operation which was performed upon him last week for the removal of an abscess which had formed in the mastoid process back of the left ear. The operation involved the opening of a channel through the bones of the skull.

New Wrinkle Editor.

Secretary Farrand sends us the following news item: "Mr. H. C. Abell, a business associate of Mr. Henry L. Doherty, has accepted the appointment of Wrinkle editor for the Denver-Colorado Springs convention of the National Electric Light Association. Mr. Abell has discovered a great many wrinkles in connection with central station operation, and knows where to learn of a great many more, that, acting homœpathically, will tend to remove wrinkles of care from the brows of all the central station managers fortunate or wise enough to be members of the association."

Standard Wiring.

Mr. H. C. Cushing, Jr., author of the hand book "Standard Wiring for Electric Light and Power," as adopted by the Fire Underwriters of the United States, has just brought out the 1905 edition of this book, completely revised to date.

Mr. Cushing, in revising this new edition, was successful in securing the services of Mr. F. E. Cabot, secretary of the Boston Board of Fire Underwriters, and chairman of the Electrical Committee of the Underwriters' National Electric Association, to assist him with that part of the book which treats of the underwriters' rules and requirements, and also the assistance of Mr. George T. Hanchett, consulting electrical engineer and member of the American Institute of Electrical Engineers, in checking up and revising many valuable tables and formulæ to aid practical wiremen and contractors in determining the proper sizes of wires for all manner of construction work for both alternating and direct currents.

This new edition, like all previous editions, is handsomely bound in flexible leather, and makes a most complete and accurate pocket companion for the practical electrical engineer, central station man, wireman and contractor, as well as an accurate guide for the architect and builder, many of whom are now called upon to embody, not only in their specifications, but in their plans, provision for the electrical construction in buildings and structures of all kinds.

"Standard Wiring" is recognized all over this country as the authority on electrical wiring and construction, being the only book on the subject which is revised and brought up-to-date every year.

All Due to Electricity.

The greatness of Greater New York has received a wonderful impetus by the successful adaptation of electricity to rapid transit. Few people whose business confines them to the city prefer to live on Manhattan Island, and when the rapid transit facilities which will be inaugurated within the so-called "electric zone" are perfected, there will be no excuse for their doing so. Then Tarrytown will be as near as Yonkers, and Yonkers will be brought within such easy access that Greater New York's growth to the north will result in a solid city for 25 miles from the battery along the Hudson. The birth of a new era in suburban growth is at hand.—*From " The World's Progress," in Four Track News for February.*

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED JAN. 24, 1905.

Electric Railways and Appliances.

780,502. Third Rail. Alfred H. Hopkins, Chicago, Ill Filed Nov. 18, 1904.

780,568. Method of Controlling Electric Railroad-Brakes. John S. Lockwood, Kansas City, Mo. Filed April 16, 1903.

780,620. Trolley-Wire Finder. Joseph P. Reed, Muncie, Ind., assignor of one-half to Salathiel R. Babcock, same place. Filed Sept. 17, 1904.

780,698. Electric Railway. Frank Anstett, Wilkes-Barre, Pa. Filed Aug. 9, 1904.

780,767. Electric-Railway Trolley. Russia R. Weeks, Cincinnati, O. Filed April 14, 1904.

780,885. Railway Electric Signal. Slaughter W. Huff, Baltimore, Md. Filed Jan 17, 1898.

Electric Lights and Appliances.

780,523. Contact for Electric Hand-Lamp. George L. Patterson, New York City. Filed April 6, 1904.

780,613-780,678. Incandescent Lamp and Incandescent-Lamp Socket. Henry E. Meyers, Denver, Col., assignor to the Electric Flash Light Company, same place. Filed Nov. 24 and Dec. 11, 1902. Renewed June 20, 1904.

Electrical Machinery and Apparatus

780,503-504. Controller for Alternating-Current Electric Motors. Ray P. Jackson, Wilkinsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed June 6, 1904.

780,507. Apparatus for Testing the Insulation of Coils. Edmund W. Kellogg, Newtonville, Mass. Filed Oct. 6, 1904.

780,544. Thermal Cut-Out for Electric Circuits. Theodore Varney, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed Sept. 22, 1902.

780,545. Means for Measuring the Energy of Alternating-Current Circuits. Miles Walker, Wilkinsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed Feb. 28, 1903.

780,547. Starting-Switch for Electric Motors. John B. Wiard, Lynn, Mass., assignor to the General Electric Company. Filed May 27, 1904.

780,549. Explosive-Engine. John G. Callan, Lynn, Mass., assignor to the General Electric Company, Filed Sept. 4, 1903.

780,550. Electropneumatic Control System. Eugene R. Carichoff, East Orange, N. J., assignor to the General Electric Company. Filed June 30, 1904.

780,555. Electric Igniting System for Vapor-Engines. Albert E. Doman, Elbridge, N. Y., assignor to the Elbridge Electrical Manufacturing Company. Filed July 7, 1902.

780,580. Control of Electric Motors. George W. Remington, Schenectady, N. Y., assignor to the General Electric Company. Filed June 26, 1902.

780,724. Dynamo for Train-Lighting. James F. McElroy, Albany, N. Y., assignor to the Consolidated Car Heating Company. Filed June 6, 1902.

780,754. Electrically-Operated Valve. Oscar Jungren, Schenectady, N. Y., assignor to the General Electric Company. Filed Aug. 24, 1903.

780,769 770. Electric Meter. James J. Wood, Fort Wayne, Ind. Filed Feb. 11 and May 10, 1904.

Telephones and Telephone Apparatus.

780,525. Telephone-Dial. Charles D. Reeve, Grand Rapids, Mich. Filed June 9, 1904.

780,601. Central-Supply Telephone System. William W. Dean, Chicago, Ill., assignor to the Kellogg Switchboard & Supply Company. Filed March 22, 1901.

780,679. Apparatus for Telephone Switchboards. Frank R. McBerty, Evanston, Ill., assignor to the Western Electric Company. Filed Jan. 26, 1901.

Miscellaneous.

780 564. Charging Storage Batteries John L. Hall, Schenectady, N. Y., assignor to the General Electric Company. Filed July 13, 1903.

780,663. Method of Operating Printing-Telegraph Receivers. John M. Joy, New York City, assignor to the Page Machine Company, same place. Filed Aug. 1, 1902.

780,664. Printing-Telegraph Receiver. John M. Joy, New York City, assignor to the Page Machine Company, same place. Filed Aug. 5, 1902.

780,842. Method of Receiving Electromagnetic Waves or Other Feeble Signal Impulses. Frederick K. Vreeland, Montclair, N. J., assignor to the Wireless Telegraph Exploitation Company, New York City. Filed Aug. 1, 1904.

THE TELEPHONE WORLD.

Big Telephone Deal Reported.

The Pittsburg "Press" on Friday afternoon last published the following introductory to a two-column article: "The stockholders of the American Telephone & Telegraph Company of New York will be notified in a month hence at the annual meeting to be held at Boston of a deal by the directors of the corporation through which the concern has secured an interest in 43 telephone companies in the United States, reaching from New England to the Pacific Coast and from the Gulf of Mexico to far into the territory of Canada. They will also be asked to authorize the executive committee to sanction the building of 90 miles of long-distance trunk lines to complete a transcontinental system which will enable the subscribers of the various companies interested to talk from Maine to San Francisco and from Texas to Canada."

National Organization to Compete With Bell Company.

Representives of various State associations of Independent telephone companies met last week in Indianapolis, Ind., and took preliminary steps toward forming the National Inter-State Telephone Association, which is organized for the purpose of forming a more compact body to compete with the Bell Company. The constitution adopted provides for the organization of the various States and districts traversed by the Independent companies.

The representation will be on a delegation basis, one delegate to be elected by the State or district association for every 10,000 units represented. The units are based on the number of telephones in use.

In a decision filed by the State Circuit Court at Cincinnati, O., it is declared that the Independent Telephone Company, organized to enter the Cincinnati field, has not yet secured the right to appeal to the courts for a franchise, some of the formalities as to the application to the city council not having been properly complied with. The case will be appealed.

The Colorado Telephone Company is sending out to its subscribers in Colorado Springs circular letters announcing a material reduction in service rates in that city as follows: One-party business lines from $100 to $72 per annum; one-party residence lines from $66 to $48; two-party business lines from $78 to $60, and two-party residence lines from $54 to $36.

The Bell Telephone Company has cut the rate from Monroe, Mich., to Toledo from 25 cents to 10 cents for three minutes' talk to meet the rate of the Stoddard Telephone Company, a Monroe Independent Company, and a merry 'phone war is now predicted.

The Michigan State Telephone Company has arranged to release the property of the Detroit Telephone Company. The receivers of the latter have obtained the necessary permission from the United States Supreme Court.

The Keystone Telephone Company of Philadelphia is to be reorganized as to finances, and its development otherwise facilitated without delay.

Iowa Telephone Men to Meet in March.

It is probable that at the annual meeting of the State Telephone Association to be held in Des Moines March 13 and 14 the arrangements for a clearing house, through which all toll line moneys will pass, will be made. At the meeting last year this was discussed, but the plan was not well worked out. Since that time further details have been arranged, and the plan will probably be adopted. Much interest centers in these meetings in view of the rapid growth of telephone companies in Iowa.

May Combine Independent Lines.

The consolidation of all the Independent telephone lines operating in the vicinity of Clearfield, Pa., was considered at a meeting of the directors of the Huntington & Clearfield Telephone Company and other Independent operators, held in Clearfield a short time ago. The prospective consolidation will result in the extending of the Independent line of the Huntington & Clearfield to Pittsburg, Philadelphia and other important places.

At the recent annual meeting of the York State Telephone Company, held in Elmira, stockholders were present from Philadelphia, Binghamton, Elmira and other places. The board of directors elected consists of 21 men, most of whom are from Pennsylvania. On the board are Thomas B. Crary, of Binghamton, and Eugene Dillon, Boyd McDowell, H. C. Mandeville, Myer Friendly and L. H. Murphy, of Elmira. The directors elected W. D. Barnard, St. Davis. Pa., president; Edward Davis, Philadelphia, vice-president; D. M. Yarnall, Philadelphia, treasurer; Boyd McDowell, Elmira, secretary, and George B. Wright, Binghamton, general superintendent. A proposition to reduce the capital stock of the company was brought up, but after slight discussion, action on it was postponed for three months.

The citizens of Chapel Hill, Tenn., and vicinity, have decided to have a telephone exchange at that place. They will secure a switchboard from the Cumberland Telephone Company and will furnish the poles and employ their own operator. A large number of prominent farmers will have boxes in their residences.

The Philadelphia & Reading, Pa., Railway Company proposes establishing a telephone service along its main line to be used at points where there are no telegraph offices, such as sidings, etc. It has been decided that the telephone is a most valuable adjunct in the satisfactory operation of railroads.

P. L. Hensel, superintendent of the Central Union Telephone Company at Pekin, Ill., has resigned and has taken a position with an Independent company in Chicago.

The Home Telephone Company of Cassopolis, Mich., has filed articles of association with a capital stock of $25,000.

The Petersburg, Ill., Telephone Company, with a capital stock of 20,000, is in process of organization.

Clearing House for Independents to be Established.

A clearing house for the Independent companies of Nebraska is to be established. A favorable report was submitted by the committee to which was assigned the duty of meditating upon this proposition, and it was adopted by the telephone men. In co-operation with the executive board it will perfect a plan for a clearing house by which all the toll lines of the Independent companies may secure a just division of long-distance tolls. A report is to be made on this some time in March, to be carried to every board of directors in the Independent telephone business with recommendations for adoption. All who join, according to present plans, must sign a contract to belong for two years. On the committee are J. C. Killarney, Auburn; F. E. Ebersole, Lincoln; G. T. Everett, Columbus; W. E. Bell, York, and T. H. Pollock, Plattsmouth.

Telephone Society Formed.

The Telephone Society of Pittsburg, Pa., was lately organized by the employes of the Central District & Printing Telegraph Company, for the mutual advancement of its members. The officers were elected as follows. S. F. Grace, president: W. W. Read, vice-president, and W. W. Benton, secretary and treasurer. The executive committee consists of R. A. L. Snyder, G. K. Smith and W. H. Gallagher. S. P. Grace, chief engineer of the company, read a paper entitled "Aerial Cable, Distributing Systems."

The annual meeting of the stockholders of the Hamlin, N. Y., Telephone Company was held a short time ago. This company was incorporated by the business men and farmers of the town of Hamlin May 12, 1904, for the purpose of giving direct telephonic communication between the villages of Morton, Troutburg, Sunnyside Beach and intermediate territory located inside the town of Hamlin. Construction work was commenced at once and July 15 the exchange opened with 25 subscribers which had grown to 160 when cold weather set in. At the annual meeting it was voted unanimously to increase the capital stock from $5,000 to $10,000, which will be held entirely for subscribers of the company.

The Clifton Springs, N. Y., Telephone Company has been purchased by the Consolidated Telephone Company of Buffalo and the management has been vested with Fred S. Bronson of the Geneva Telephone Company. The Clifton Springs Exchange has at present about 100 'phones. The new owners will rebuild the entire system in Clifton Springs and place it on a thorough up-to-date basis.

J. C. Crowley, manager of the People's Telephone Company of Duluth, Minn., recently appeared before the council and stated that his company wished to raise some money on its plant, and proposed issuing $100,000 worth of bonds.

The Iowa Telephone Company is preparing to construct eight telephone lines out of Des Moines, commencing early in the spring.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Albion, Mich.—The council has granted a franchise to the Albion Electric Light Company for 30 years.

Brownsville, Tex.—The People's Ice & Manufacturing Company will erect an electric light plant for which a franchise was recently granted.

Buffalo, N. Y.—Commissioner of Public Works Ward will soon have to prepare and present to the board of aldermen estimates of what an electric lighting and power plant will cost this city.

Camden, Tenn.—Stock has been subscribed for putting in an electric light plant here.

Colorado Springs, Col.—The Nob Hill Improvement Society is considering the matter of lighting the residence district by electricity, the same to be extended from the city electric lighting system.

Flora, Ind.—The town board of trustees has granted a franchise to David E. Miller to construct an electric light plant,

Fort Valley, Ga.—The council has caused an election to be held February 24 to vote on the question of issuing bonds to the amount of $12,000, for the purpose of establishing an electric light plant, and an extension to the present waterworks system.

Gillett, Wis.—The proposition to issue bonds to the amount of $6,000 for the installing of an electric light plant was lately carried.

Iola, Wis.—J. G. Fromer will erect an electric lighting plant in this city.

Jackson, Mich.—W. A. Foote will erect a new electric light and power plant in this city to cost $100,000.

Lake City, Ia.—It is said that the Lake City electric light plant will be sold under the hammer.

Laurel, Miss.—The electric light plant and power plant of the Laurel Improvement Company was lately destroyed by fire to the extent of $14,000. The company will rebuild at once on a larger scale.

Leesburg, Va.—W. E. Crosen & Co., of this city, have applied to the city council of Manassas, for a franchise for the erection of a system of electric lights during a period of 15 years. The proposed plant will have a capacity of 750 standard 16 cp. lamps.

Manitowoc, Wis.—The city engineer has been directed to prepare estimates on the cost of an electric light plant.

Marcellus, Mich.—The electric light and water department of this city, will install a new engine and other apparatus for its municipal plant.

McKinney, Tex.—A new electric light plant will soon be established here. The issuance of bonds to the amount of $8,000 have been sold.

Metuchen, N. J.—The Public Service Corporation Company has another rival. This time it is the Metuchen Gas & Electric Light Company, which was organized here with a capital of $50,000.

Obion, Tenn.—The people of this place will soon hold an election to decide the question as to whether an electric light plant shall be established here.

Paris, Ky.—This city is considering the erection of an electric light plant, and James M. O'Brien, W. H. Weele and T. P. Woods have been appointed a committee to investigate the cost, etc.

Pryor Creek, I. T.—R. H. Berry, of Lincoln, Mo., is reported as organizing a company to establish an electric light and ice plant.

Royse City, Tex.—The Royse Milling & Light Company has been incorporated with a capital of $20,000, by J. E. Poynter and others, to operate an electric light plant and grist mill.

Savannah, Ga.—Keller Brothers will erect an electric light plant in this city.

Silver Creek, Neb.—A movement is on foot to establish a system of electric lights here with fair prospects of success

Sturgeon, Mo.—The board of aldermen has ordered a special election to be held February 6, to vote on bonding this city to install an electric light plant.

Springfield, O.—A new electric lighting plant with modern equipment is to be built here by the American Railways Company. C. L. S. Tingley is secretary.

Tennille, Ga.—The money for the purchase of bonds recently issued by this city has been received. The bonds were issued for the purpose of extending the waterworks system and installing an electric light plant.

STREET RAILWAYS.

Alma, Mich.—The Alma Sugar Company will build an electric road in Emerson and Lafayette Townships.

Ames, Ia.—Steps are being taken to build an electric line between here and the Iowa Agricultural College.

Delta, Col.—The board of county commissioners lately granted an electric road franchise to W. B. Stockham and Charles Pike. The road will consist of two lines, one of which will run from this city to the Grand Mesa Lakes via Eckert, Cedar Edge and the four coal banks on Surface Creek. The other branch goes from Delta to the Smith's Fork anthracite coal fields. The entire distance will be about 90 miles.

Ft. Wayne, Ind.—Dr. Greenwell, of Huntertown, has been granted a franchise for the erection of a trolley line in this city.

Gault, Ont.—Hon. Charles D. Haines, who has undertaken the building of the Hamilton, Ancaster & Brantford Railway, also intends to promote electric lines in Guelph and this place He has had a route laid out which overcomes the heavy grades and reduces the cost of construction.

Keyser, W. Va.—A franchise has been granted by the city council to the Keyser, Burlington & Petersburg Electric Car Company of this city.

Lima, O.—The Lima, Findlay & Toledo Railway, with headquarters in this city, has been formed to construct and operate an electric line from here to Findlay. Capital stock is $700,000. Frank Butler, E. Sanburn, N. S. Harris and others, are the directors.

Lincoln, Neb.—The business men of this city are planning to organize a company for building an electric line.

Milwaukee, Wis.—The electric line from this city to Racine and Kenosha will be rebuilt this spring.

Owego, N. Y.—An electric railway between here and Binghamton is now practically assured. It will be built during the coming summer.

Selinsgrove, Pa.—It is said the right is to be secured for a Pennsylvania trolley line from Lewistown to this place and thence to Sunbury by a bridge over the Susquehanna at Shamokin Dam.

Tekanah, Neb.—L. F. Wakeheld and C. C. Pierce, of Sioux City, Ia., have the contract to build an electric line from here to Decatur.

Versailles, Ky.—The city council has granted a franchise to Clifford B. Bebee, of Syracuse, N. Y., for the right of way through this city for an electric railway.

POWER PLANTS.

Bristol, Conn.—The New Departure Manufacturing Company contemplates the erection of a power plant, and will install a turbine engine.

Edwardsville, Ill.—The power plant of the Edwardsville Electric Light & Power Company has been purchased by the syndicate in control of the Illinois Central Traction Company's interurban road. New machinery will be installed and the plant improved.

Glenwood Springs, Col.—Work will shortly be commenced on the new power plant of the Colorado Irrigation & Power Company in the canon of the Grand River near this place. L. W. Beard is chief-engineer of the company.

Tlacotalpan, Mex.—The San Defonso Woolen Factory, located near here, has applied to the Mexican Government for a concession to establish an additional power plant for the operation of its factory.

BIDS WANTED.

Cleveland, O.—Sealed proposals will be received at the office of the board of education, Rose Building, this city, until 11 o'clock February 25, for the furnishing of electric power to the various public schools in the school district. Address Charles Orr, director of schools,

Glenwood, Ia.—Bids will be received for a power house for the School for Feeble Minded.

Greensboro, N. C.—The Cape Fear Manufacturing Company of this place will contract for a 100 hp. engine and a 125 hp. boiler.

Greenwood, Miss.—The board of supervisors of Le Flore County, Miss., will open bids March 6 for steam heating, plumbing and electric wiring of the court house, according to plans on file in this city at the office of C. W. Crockett, clerk.

San Francisco, Cal.—Sealed bids will be received in triplicate at the office of Capt. W. C. Wren, quartermaster, United States Army, constructing quartermaster, Phelan Building, this city, until February 13, for the construction, plumbing, electric wiring, etc., of 21 buildings at Point Bonita, Cal., in accordance with plans on file at the office of the depot quartermaster, Seattle, Wash., or Portland, Ore.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 15⅛@15¼c.; Lake 15¼@15⅜c.; casting, 14⅞@15c.

We are informed that the Massachusetts Electric Companies is prepared this year to meet all its financial requirements.

The New England Telephone & Telegraph Company has declared the regular quarterly dividend of 1½ per cent., payable February 15.

General Electric insiders claim that the company's net profits are estimated to be running now at the rate of about $1,000,000 a month.

Application has been made to the New York Stock Exchange to list $3,000,000 Western Union Telegraph Company refunding and real estate mortgage bonds of 1950.

The situation in the copper market remains unchanged. The market is extremely dull, but very firm. There is very little copper offered, and there is a correspondingly slack desire to buy.

Application has been made to the New York Stock Exchange to list $5,250,000 additional first refunding mortgage 4 per cent. bonds of 2002 of the Brooklyn Rapid Transit Company.

February dividend disbursements in New York are estimated at $31,697,164; interest, $23,444,688; total, $55,141,852, as compared with $61,734,200 in February, 1904, and $63,556,985 in February, 1903.

The directors of the Wagner Electric Manufacturing Company, St. Louis, voted a quarterly dividend of 1¾ per cent. It is expected that the business for 1905 will show a large increase over that secured in 1904.

The Iroquois Electric Company of Buffalo, N. Y., has been incorporated with a capital of $1,000,000 to manufacture electricity for light, heat and power purposes in the villages and towns in Erie and Niagara Counties.

It is expected that the Philadelphia Rapid Transit Company's earnings for the month of January will show an increase of over $100,000. Present earnings indicate that the gross for the year will not be far from $17,000,000.

The Havana Electric Railway Company has applied to the New York Stock Exchange to list $8,250,000 consolidated mortgage 5 per cent. 50-year gold bonds of 1952; $5,000,000 6 per cent. non-cumulative preferred stock, and $7,500,000 common stock.

It is understood that practically 80,000 shares of the Chicago City Railway stock have been deposited under the offer of the Morgan-Mitchell-Field syndicate of $200 a share provided a majority of the capital and the control of the property is turned in.

At the annual meeting of the stockholders of the Brooklyn Rapid Transit Compnay the four retiring directors were reelected. The stockholders also voted to confirm and approve all the acts of the directors of the executive committee for the past year.

Upon application of the Chicago Union Traction Company and the City Railway Company, Judge Grosscup, in the United States Circuit Court in Chicago on Monday, granted a temporary injunction restraining enforcement of the universal transfer ordinance recently adopted by the Chicago City Council. The ordinance, it is alleged, impairs a contract between the traction companies and the State, and therefore is in violation of the Federal constitution.

EDITORIAL NOTES.

The Load Limit of Great Power Generators.

Large units, as they are called, have taken the place of many small units in power stations. The argument, as formerly advanced, was "use small units, so that in case of breakdown there will be enough generators in operation to continue the service." The danger of a breakdown at the time this idea prevailed, was greater in power plants than it is to-day. Breakdowns were due to the armature burning out, to hot bearings from a continuous high speed, or to the evil effects of lightning discharges. The difficulty of distributing the load fairly was one of the defects of early station design. The next difficulty was that of building generators to stand the wear and tear of continued strain. A great many lessons were learned from these early experiments in station construction and operation. One of the first was to build generators capable of standing a larger percentage of overload.

The next was a full comprehension of the necessity for building larger generators. And finally, the third important conclusion arrived at was, that a few large slow speed generators were in every way preferable to a series of small high speed machines. The large unit, in other words, predominated, and in consequence its construction was designed with reference to that very important factor, the factor of overload. The load limit of great power generators is such to-day that they will stand the heaviest strain without flinching. A 25 per cent. overload is not uncommon and cases have been recorded of a 50 per cent. overload for many hours. When we speak of overload we mean heat and sparking. By this is meant that a dynamo is a heat-developing machine. If it rises but little in temperature at full load, its capacity is naturally greater than a dynamo which heats up quickly under similar circumstances.

Holding the sparking in check as well as the temperature in giant generators of direct current construction is one of the triumphs of modern electrical engineering. The difference in the capacity of a 100 kw. dynamo, operating at the north pole and at the equator respectively, would be at least two to one.

The point of importance here is that a well-ventilated engine room means coolness, and a greater capacity in consequence of the generators in action. The latest design of power stations takes this fact into consideration for this and other reasons as well.

Large units with their slow speed and slowly rising temperature are thus the natural result of a chain of reasoning that is backed up by expensive experience. It is more through this success, perhaps, than anything else that electric lighting now rests upon a firmer technical and business basis. The most reliable machines in service to-day are unquestionably the heavy generators of our biggest stations engaged in supplying electricity for light and power.

* * *

Leave Well Enough Alone.

Last week a reader of the New York "Evening Journal" wrote and asked that paper for arguments in favor of municipal and Government ownership.

The answer appeared in the form of an editorial such as the "Journal" alone is capable of producing. It said: "Statistics on the matter are not lacking. In Germany, France, England, in New Zealand especially, Government and municipal ownership have been thoroughly tested. In every case practical results have justified and supported the theoretical idea of honesty and social common sense underlying the ownership of public monopolies by the people themselves."

It is true that statistics are not lacking, but the "Journal" takes particular pains not to give any.

In Germany, Russia and a few other countries the railroads are Government enterprises, and being operated under iron-clad rules, the employes subject to military discipline, they have proven fairly satisfactory to the inhabitants of the countries in which they are located. But the methods and the system in vogue in those countries would not be tolerated by the people of the United States. There is too much "red tape" and deliberateness, and it is this that has made them as successful as they are.

Furthermore, conditions and ways of life abroad are radically different from what they are in this country. In Germany, France, Russia and even England, men are content to get rich by the slow process of saving, whereas in the United States men accumulate wealth not so much by saving as by reaching out and grasping. And, sad to relate, a great many are not particular how they reach and grasp.

The Post Office is a Government enterprise and is supposed to be run for the benefit of the people, yet a recent investigation disclosed, to say the least, a very unsatisfactory condition of affairs. The Police Department in this city is a municipal enterprise, supported by the people and supposed to be for the people, and yet when men and women are held up on the street and robbed in broad daylight, and members of the force get independently rich in a few years on salaries ranging from $3,000 to $5,000 a year, there must certainly be something wrong with this municipal undertaking.

One of the arguments advocated by the "Evening Journal" in discussing Government ownership is as follows:

"I know that railroads well managed in the interests of the public would mean increased happiness for all of the people. I know that the railroads, managed by private, selfish interests, are used against a majority of the people and to promote the interests of a selfish few."

The gist of the whole argument, if argument it can be called, lies in the two words "well managed." Would the railroads of this country or any other great undertaking be well managed by politicians and hangers-on, with changes taking place every four or eight years through the incoming of a new administration?

President Roosevelt says: "We can as little afford to tolerate a dishonest man in public service as a coward in the army," and yet scores of dishonest men creep into politics, and they are the ones that would cause through avaricious motives municipal and Government enterprises to be a failure.

* * *

How the Telephone Trust Makes Money.

A bill has been introduced into both branches of the New York Legislature with a view to controlling telephone monopoly as far as it exists in this city.

The bill in question provides for the amendment of the transportation corporations law so as to provide that telephone companies may not charge their regular subscribers toll or additional compensation for any message sent through its instruments or over its wires to any place within any of the separate boroughs of the City of New York and which does not take more than five minutes to send; and no greater charge than ten cents shall be made for the use of a public telephone for the transmission of a like message not exceeding five minutes to send, nor more that ten cents for each additional five minutes to send within any of the separate boroughs of the City of New York.

Referring to the subject Senator Keenan, who is one of the minority members of the Senate Finance Committee, before which are now pending the joint resolutions for legislative inquiry into the Gas and Electrical Trusts, is reported as saying:

"The Gas Trust is a pigmy compared with the Telephone Trust. It is an outrage that all sorts of prices are charged for interborough telephone messages. A three-minute message between Queens and the Bronx now costs 35 cents. Until recently it cost 40 cents, even between points both lying in Queens County. Between Newtown and Flushing a call costs 15 cents, although a five-cent carfare prevails. Rates at present from various boroughs of the consolidated city are all the way from 20 cents up. No other city in America has to pay such exorbitant charges. The earnings of the companies comprising the trust are enormous and they certainly warrant a reduction of the tolls. Ten cents a message within any part of New York City ought to be enough."

Not many miles from New York across the Hudson River are two towns situated about two miles apart. A telephone exchange belonging to the New York and New Jersey Telephone Company is located in the larger of these towns and less than a score of private telephones in the smaller. The telephone charge is $2 a month for a four-party line which entitles a subscriber in the smaller town where there are practically no 'phones to call up any one that has a 'phone as often as he pleases. Whenever a connection is wanted the central in the larger town has to be rung up. Now comes the point. The object in having a 'phone put in by residents of the smaller place is to enable them to call up their tradesmen or friends in the larger town, and until very recently each such call cost the smaller town subscriber just 15 cents extra per message.

These prices prevailed for several years in spite of remonstrances and kicks on the part of the small town subscribers. For some, no doubt charitable, reason the monopoly saw fit a few months ago to send out notices that if the small town subscribers would make new contracts the heretofore 15-cent call would thereafter be reduced to 10 cents—which is still an imposition.

Several Senators are reported from Albany as saying that what is wanted to get through a bill regulating telephone rates is facts. Let, therefore, some recognized body of business men in this city get together with a view to forcing an inquiry and procure the necessary *facts*. They should not be so hard to get.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

We will pay 25 cents for a copy of ELECTRICITY of October 19, 1904.

◆

The annual dinner of the American Institute of Electrical Engineers will be given to-night (Wednesday) in the grand ball-room of the Waldorf Astoria. There will be a number of interesting speakers and an original menu has been prepared appropriate to the occasion.

◆

Mr. H. H. Vreeland, president of the New York City Railway Company, will deliver an address before the New York Electrical Society February 15 on the development of street railway systems.

◆

A cable dispatch from Paris says that an important discovery of a radium mine in the Department of Saone-et-Loire is interesting scientific circles. Prof. Curie's assistant is conducting the exploitation.

◆

While discussing the subject of the electrification of steam railroads Senator Chauncey M. Depew made this prediction:

"In ten years from now the steam locomotive will be in the museums, while we will be carried along, clipping the seconds off 75 miles an hour, by electric locomotives."

On January 24, Judge Kohlsaat in Chicago granted a preliminary injunction in the case of the Weston Electrical Instrument Company against the Jewell Electrical Instrument Company. Mr. William Kenyon, of the firm of Kenyon & Kenyon of this city, and Mr. C. A. Brown of Chicago were counsel for the complainants. Mr. Edward Weston was present at the hearing.

The committee of arrangements of the International Association of Municipal Electricians will meet at Erie, Pa., February 13, to make arrangements for the next convention.

The "Lancet" of London has made the discovery that there is 100,000,000,000 tons of gold in solution in the oceans of the world and that steamers might be able to collect a reasonable quantity by suspending in the sea copper plates connected with dynamos. At the end of a voyage the plates could be examined for gold, says the "Lancet," and some idea of the practicability of recovering the metal would be gained. This is the first time the question of extracting gold from the sea has been brought up since the Rev. P. F. Jernegan's Electrolytic Marine Salts Company's bubble burst with such disastrous effect in 1898.

In spite of the prolonged agitation on the subject, only five municipalities in Great Britain have established telephone plants, and 41, after investigation, have decided not to do so.

An English dentist is reported as having invented a sleeping bunk for steamers which will remain level in any sea. The cot is suspended in a steel frame-work from the roof of one of the deck cabins, and the motion of the boat is counteracted by four cords from each corner which passes through electric brakes. These automatically maintain the cot in a horizontal position. The berth is also fitted with a water mattress and has an electric fan, which can be set in motion by touching a button and drives a delicious draught of air across the face of the occupant.

The annual meeting of the American Electrochemical Society will be held in Boston and Cambridge, Mass., April 26 to 27. Among those who will contribute papers are Messrs. Carhart, Blake, Reuterdahl, Richards, Bancroft, Noyes and C. Gordon Richardson. The headquarters will be at Hotel Lenox.

The Secretary of the Treasury has asked Congress to make an appropriation of $60,000 to enable him to install and maintain electric burglar-alarm devices in connection with vaults and safes in buildings under the control of the Treasury Department during the fiscal year ending June 30, 1906. This appropriation will provide for protection additional to and separate from that authorized by the sundry civil act of March 3, 1903.

Mr. William H. Blood, Jr., has the chairmanship of the committee on district heating for the National Electric Light Association, and expects to present a very full and important report on this branch of central station industry. The other members of this committee are Mr. C. R. Maunsell, of Topeka, Kan., and Mr. R. S. Wallace, of Peoria, Ill., both of whom have had personal experience with steam and hot-water heating plants, as well as having given the subject extensive study and observation. A liberal appropriation has been made by the association for carrying on investigations.

THE GREAT PROBLEM OF MUNICIPAL LIGHTING PLANTS IN LARGE CITIES.

The question of what is a city's business can be answered in various ways. To some, it is anything which concerns the public; to others, it is only the routine of city life. There are times when certain matters which relate to questions of municipal economy arise; they are seized hold of by the public, and as if by magic an argumentative epidemic rages. Such occasions are not infrequent, owing to the uniqueness of American institutions in this respect. The newspapers and the public keep their eyes riveted on all transactions relating to the present or future welfare of the community. As a result of this a consensus of opinion prevails which often emanates from those wholly unprepared by training or experience to arrive at such conclusions. There are times when a majority is not right because it represents a preponderance of opinion. In fact, it is so frequently the opposite, that in New York and other large cities in the United States, when public opinion has ruled for one thing, it is not uncommon for it to rule the other way in a very short time. When public opinion, however, is guided by a healthy newspaper influence to the correct conclusions, then the progress of American commonwealths is being assisted to its proper goal.

One of the great questions at present occupying the time and attention of the two leading cities in this country is that of the advisability of erecting its own electric light plants, generating its own current and thus supplying its public buildings and thoroughfares with cheap and efficient illumination. Of these two cities, Chicago and New York, Chicago claims to have arrived at a successful solution of this problem. New York, standing at the threshold as it were, is about to establish as its first experiment in this direction a 400 hp. plant to be located under Williamsburg Bridge.

There are pros and cons to the question of municipal ownership that have agitated the minds of some of the greatest thinkers of the day. If there is any intention which is remote from those which represent the fundamental ideas of American institutions, it is that of having municipalities engage in competition with private institutions in any department of commerce or industry. When such causes arise, as would invite such action, the remedy is legislation. No more dignified or just method could be conceived and none more effective in cases of exorbitant charges. In either case this would seem to be the natural outcome. If a city enters into a certain industrial field, its possession of facts and figures if successful in its enterprise would force it to legislate against overcharge on the part of those supplying some great public commodity. When this happens, the original cause of so radical a move on the part of the city disappears. Low rates would then make a city plant a useless encumbrance.

The "Brooklyn Eagle" publishes a report received from Mayor Carter Harrison, of Chicago, outlining the financial history of that city's experience in the field of municipal ownership.

Judging from the statements made by the Mayor, Chicago is making money on her plant. He claims an earning power of a quarter of a million dollars a year through its operation, and contemplates extensions which represent the flotation of $200,000 worth of city bonds the present year. The statistics supplied give detailed figures from 1898 to 1903 inclusive, although the plant was initiated in 1887. At this time it was under the management or jurisdiction of the Fire Department. In 1898 a separate department of electricity was founded, and at its head was placed Edward B. Ellicott, formerly of the Westinghouse Company. Under his management the Mayor claims a successful demonstration of the advantage of municipal ownership was made in a technical and financial sense. In the following table, the money expended for the construction and operation of Chicago's electric light plants from 1887 to 1903 is given for each consecutive year:

TABLES OF EXPENDITURES FOR BUILDING AND OPERATING MUNICIPAL ELECTRIC LIGHT PLANTS.

Expended for Construction and Operation.

1887....Expended for construction.........	$39,976.25
1888....Expended for construction and operation	90,952.90
1889....Expended for construction and operation	331,616.62
1890....Expended for construction and operation	214,330.60
1891....Expended for construction and operation	214,951.98
1892....Expended for construction and operation	134,674.16
1893....Expended for construction and operation	168,169.21
1894....Expended for construction and operation	174,143.15
1895....Expended for construction and operation	180,330.08
1896....Expended for construction and operation	144,077.56
1897....Expended for construction and operation	152,493.00
1898....Expended for construction and operation	289,483.39
1899....Expended for construction and operation	347,377.14
1900....Expended for construction and operation	433,524.08
1901....Expended for construction and operation	340,205.45
1902....Expended for construction and operation	274,357.48
1903....Expended for construction and operation	319,436.35
Total	$3,850,099.40
Less one plant sold in 1893 and transfer of real estate...........................	130,000.00
Total amount expended on account of plants..	$3,720,099.40

The sums range from about $40,000 in 1887 to over $319,000 in 1903. This covers the cost of from 200 lights in 1888 to about 5,000 lights in 1903. In 1893 the lighting system of Chicago was represented by a series of plants called plant No. 1, plant No. 4, plant No. 6 and plant No. 8. In 1899 it was represented by plant No. 1, the R. A. Waller plant, plant No. 6 and No. 8. In 1900 it consisted of plant No. 1, the R. A. Waller plant, plant No. 4, plant No. 6 and plant No. 8. In 1900 the same plants were in use. In 1901 plant No. 4 was not in use. In 1902 only the R. A. Waller, No. 6 and No. 8 plants were in use, and in 1903 the last three plants were performing the entire service for the city. It can hardly be said that these plants are very much up-to-date, nor do they represent the investment which would be required to equip a thoroughly modern plant with all the essentials of a large and elaborate service. For the purpose of establishing a basis of comparison the following table is presented which shows the estimated cost of an equal amount of lighting to that done by the city plant during the current years. The rates then prevailing are given and the amounts thus calculated. According to these figures, 1903, the last year given, shows an estimated cost at the prevailing rates of about $560,000 as compared with the actual cost of $319,436, a difference of over $250,000:

TABLE OF AMOUNTS RENTED ELECTRIC LIGHTS WOULD HAVE COST FOR CORRESPONDING PERIOD.

Number of lights operated by city and cost of same, if rented:

1888....192 lights if rented would have cost at $200.00.........................	$38,400.00
1889....297 lights if rented would have cost, at $185.00.........................	54,945.00
1890....900 lights if rented would have cost, at $175.00.........................	157,500.00
1891....993 lights if rented would have cost, at $175.00.........................	173,775.00
1892....1,102 lights if rented would have cost, at $175.00.................	192,850.00
1893....1,112 lights if rented would have cost, at $156.25.................	173,750.00
1894....1,108 lights if rented would have cost, at $137.50.................	152,350.00
1895....1,116 lights if rented would have cost, at $137.50.................	153,450.00
1896....1,254 lights if rented would have cost, at $137.50.................	172,425.00
1897....1,438 lights if rented would have cost, at $137.50.................	197,725.00
1898....1,710 lights if rented would have cost: 272 at $105.00, and 1,438 at $137.50	226,285.00
1899....2,893 lights if rented would have cost: 1,297 at $105.00, and 1,596 at $137.50.........................	355,635.00
1900....3,867 lights if rented would have cost: 2,136 at $103.00, and 1,731 at $137.50.........................	458,020.50
1901....4,305 lights if rented would have cost: 2,551 at $103.00, and 1,754 at $137.50.........................	503,928.00
1902....4,508 lights if rented would have cost: 2,754 at $103.00, and 1,754 at $137.50	524,837.00
1903....4,827 lights if rented would have cost: 3,008 at $103.00, and 1,819 at $137.50.........................	559,936.50
Total amount rented lights would have cost...	3,895,812.00

A very interesting situation now presents itself, when the total cost of the series of municipal plants dating back from 1887 to 1903 is compared with the total hypothetical outlay at the then prevailing rates during the same period of time.

Under the head of the amounts that *would* have been spent for electric lighting from 1888 to 1903 is found a total for all those years of $3,895,812. Under the head of expenditure for building and operating the plants for an equal period and for the supplying of an equal number of lights is found a sum total of $3,720,099. These two sums are the foundation for interesting conclusions according to these records. They are very nearly equal to each other, considering the magnitude of the totals. The difference is $175,713 for a period of 16 years.

In other words, according to these statistics, **the money that would have been spent by Chicago for electric lighting is the money that paid for the construction and operation of its electric lighting system.** The year 1903 cost the city over a quarter of a million dollars for about 5,000 arc lamps. According to the rates quoted, the Mayor claims a saving of nearly $300,000 as shown by the following figures:

1903.

Cost of rented service, 4,827 lamps.........	$559,936.50
Cost of operation (less taxes)...............	262,888.38
Earning power..............................	$297,048.12

The proposition, from this point of view, shows that equal lighting would have cost about $300,000 more by private companies than it actually cost the city.

To quote Mayor Harrison: "The saving to the city may be more clearly understood when it is considered that in order to have the same lighting service from rented sources the appropriation bill will have to be increased $297,048.12 for the year 1903, and the revenue to the city would only be increased by 21 per cent. of what taxes might be paid by a private corporation owning and operating the system, the balance, or 78 per cent. of taxes, being assessed for other than municipal purposes."

Perhaps the taxes that would be paid in comparison with the dollars and cents saving to the city in electric light bills are small, but how about the effect of a change of rates when the private corporations have managed to clean off their indebtedness to some extent for improvements and extensions.

The danger in all such estimates is due to the basing of the need for a municipal plant upon the idea of the fixity of the rates. Let the rates fall and the tax question assumes greater importance as would the value of a municipal plant necessarily assume less.

Chicago's apparent success in this field is no guarantee of an equal success, if it may be so-called, in New York. Here the conditions are different. All wires must go underground and all lamps must burn with brightness and equality. The expense of lighting in New York is necessarily greater than that of any other city in the world. It is, on the other hand, the most perfect and the most successful. If the expense of putting all wires underground as required by the municipalty in New York were added to Mayor Harrisons figures and in addition the same high grade of lighting were done as the city streets now receive, the above figures would undergo changes to a remarkable degree.

Mayor McClellan expects in about three months to close the switch which will send the current from New York's first electric light plant to the arc lamps of Williamsburg Bridge and the adjoining school-houses in the neighborhood.

THE ELECTRICAL EQUIPMENT OF A LONDON HOSPITAL.*

While it must be admitted that medical electricity as a whole is less advanced in this country than abroad—mainly through the abuses practised in its name by quacks in the earlier days—there is no doubt that great progress has been made during the past few years. The British Electro-Therapeutic Society was formed three years ago and now numbers over 160 members. Most of the great hospitals have instituted departments for the treatment of diseases by electrical means.

The latest of these is that of Guy's Hospital, St. Thomas Street, S. E. Here a complete installation of apparatus has been laid down, for almost every description of electrical treatment now in vogue. We give herewith a brief account of the various systems installed, with illustrations of the apparatus.

No installation would be complete without the Finsen light apparatus for the treatment of lupus, which has been the means of effecting countless cures of that repulsive disease since its introduction but a few years ago by Dr. Finsen—now, alas, no longer with us.

Numerous improvements have been made in the construction of the apparatus all of which are embodied in the one here illustrated. Suspended from a strong support is an arc lamp of extremely high candle power, around which is suspended a heavy metal cylinder, serving to carry the telescopes and the necessary pipes and taps for the water-cooling of the telescopes and compressors, through which the rays pass before reaching the patient. The telescopes are constructed of brass barrel, with rock crystal lenses to concentrate the rays of the arc lamp. At the end of each telescope nearest the lamp a space is left between two of the lenses which is filled with distilled water; around this a water jacket is fitted to permit of the circulation of running water from the main supply in order to keep it cool. The distilled water fulfills the double purpose of eliminating some of the heat rays and of preventing the top lens from cracking, owing to its exposure to the great heat from the arc lamp. At the other end of the telescope for a space of about 12 inches, between two more lenses, is a column of distilled water which absorbs further heat rays. Around the four telescopes are arranged couches on which the patients lie whilst under treatment. The part to be treated is brought to the point of convergence of the rays through the telescope and compressors consisting of rock crystal lenses, between which a stream of water is continually circulating, are pressed firmly on the skin, in order to render it anæmic, as the presence of red fluid would prevent the ultra-violet rays from properly penetrating. Here occurs the final exclusion of the heat rays, and the chemical rays alone reach the patient. By an ingenious arrangement, the fullest use is made of the light from the lamp, so that the current consumption is about 50 amperes only, as against 70 or 80, or even more, in the older types.

The main features of the Finsen-Reyn lamp for lupus treatment of a single patient are very similar to the foregoing, there being an arc lamp of very high candle power arranged to project its rays through a telescope for the elimination of the heat rays and the concentration of the chemical rays to a point where a compressor is used on the patient, as with the large Finsen apparatus. A special type of self-feeding arc lamp is used with this instrument which has proved very satisfactory in working. The stand on which the apparatus is mounted is designed to give every possible movement and height required, and it is mounted on a wheeled base.

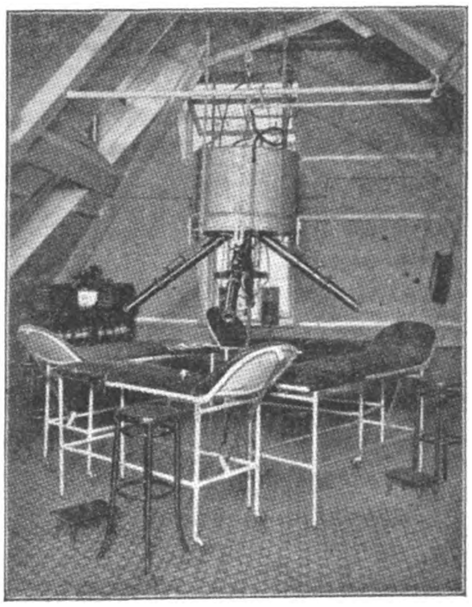

FIG. 1.
Finsen Light Apparatus.

Next follows an extremely useful lamp, also designed for the light treatment of lupus; this is a modification by the London Hospital staff of the French lamp, Lortet-Yenoud. The general construction consists of a stand having a heavily weighted base, on which is mounted a hand-feed arc lamp. The rays from this lamp are projected through a double shield having two rock crystal lenses set in its center; between these circulate water from the main supply, serving the same purpose as in the apparatus already mentioned. In the use of this lamp no compressor is required, as the part to be treated is pressed against the front lens of the shield. All the above light converging apparatus are also being successfully employed in the treatment of rodent ulcer.

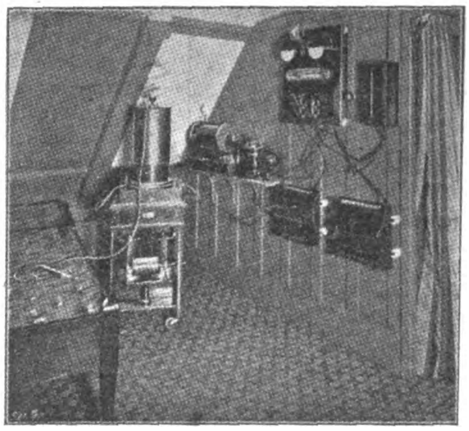

FIG. 2.
High Frequency Apparatus.

Fig. 2 illustrates a cubicle fitted for the application of currents of high pressure and high frequency, which have been used with great success in rheumatism, arthritis, anæmia, neurasthenic conditions, pruritus ani, and certain stages of pulmonary tuberculosis.

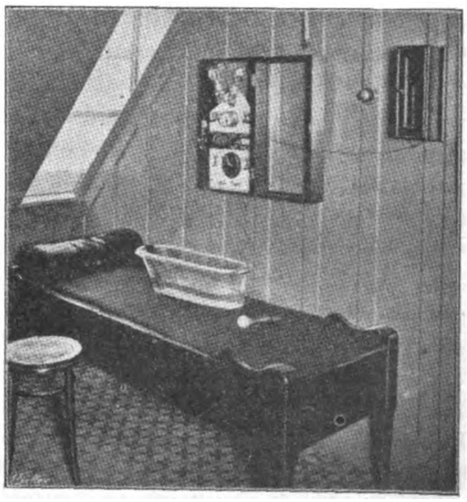

FIG. 3.
Switchboard for Galvanism, Faradism and Electrolysis.

In this installation the direct current from the main supply is utilized both for the induction coil and to actuate the motor of the mercury jet interrupter, through variable resistances; a switchboard is used in connection with them for controlling the current, having mounted on it a voltmeter and ammeter for reading the pressure and current supplied to the primary coil. From the secondary coil, which terminates at the discharging pillars, wires are led to a spark gap and Leyden jars where extremely rapid alternations of current are set up. The high frequency current passes to a solenoid composed of windings of thick copper wire, of which, by means of an ingenious arrangement, more or less can be inserted, controlling thereby the pressure which is utilized in the treatment. The current is applied through vacuum tubes, where local treatment is desired, and by the condensation method when the general electrification of the subject is considered necessary. Various other methods of treatment are also used which need not here be described.

---

*From the "Electrical Review," London.

The peculiarity of this system is that enormous voltages and quite a heavy current can be used without danger to those under treatment. The processes of metabolism seem to be those principally affected by high-frequency currents.

The next illustration, Fig. 3, shows a switchboard for galvanism, Faradism, combined current, and electrolysis. It consists of a polished marble base, whereon are mounted two resistance lamps with switches, a galvanometer with a shunt to increase the range of the instrument, a switch to reverse the polarity of the galvanic current, switch to allow a galvanic, Faradic, or combined current to flow from the terminals, Faradic coil with regulating primary and secondary, and a special circular wire rheostat of 10,000 ohms resistance, divided into 56 steps, this allowing of very fine gradations of current. Great success has attended the application of these currents, in conjunction with a special arm bath, for writer's cramp. In rheumatism, paralysis, neuralgia, etc., the treatment has also been found most efficient.

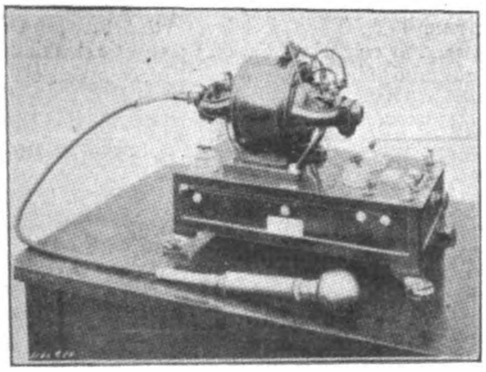

Fig. 4.
Apparatus for Vibratory Massage.

Fig. 4 shows an ingenious and useful motor transformer, wound to run on the 105-volt direct current mains. Attached to one end of the shaft is a flexible cable with a ball attachment at its extremity; this ball vibrates with various degrees of amplitude, regulated by a collar arrangement, which can be moved round while the ball is in action on the patient; the top of the ball is drilled with three screw holes to take variously shaped electrodes for the local treatment of the smaller muscles, etc., where the ball itself would be too large. This form of massage treatment is now very largely employed in many cases where formerly manual methods were used, and it has been found that the results are much better, as the form of vibration is immeasurably superior to that which may be gained by any other means. Other advantages of the motor transformer are that it can be used to give a regulated sinusoidal current to light small lamps such as head-lamps, laryngoscopes, cystoscopes, etc., and also to render a cautery point incandescent.

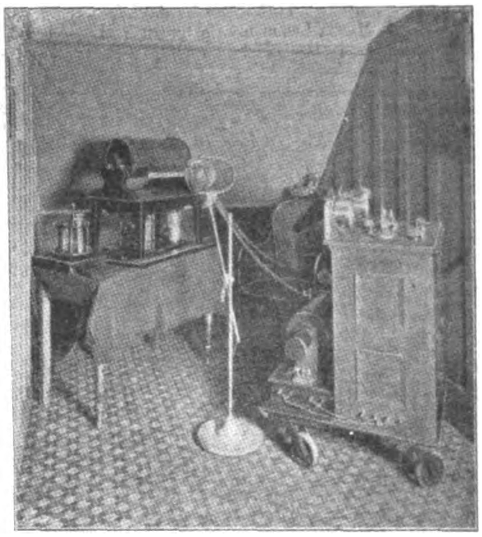

Fig. 5.
High Frequency and Roentgen Ray Apparatus.

In Fig. 5 is shown a cubicle fitted for high frequency currents and Roentgen rays for therapeutic purposes. We have already spoken of the high frequency treatment, and will now briefly describe the X-ray arrangements. The induction coil utilized is of 12-in. spark length, with a dipper type mercury interrupter. The current utilized is a direct current from the main, through regulating resistances, for the coil and motor of the interrupter respectively, volt and ammeters being in circuit to read the pressure and current used. There is a special feature about the arrangement of the X-ray tube itself for therapeutic treatment; the tube is mounted on a stand, and is inclosed in a transparent screen which entirely cuts off the rays from both patient and operator, a most important desideratum. To permit the passage of the rays to the part of the patient to be treated, there is an orifice in the globular screen, to which can be fitted various tubes of the same material; through these the rays pass directly to the affected part only, thus dispensing with the use of lead-foil protection, which was formerly necessary to prevent burns. The tubes can be sterilized, and the arrangement presents other features of great value. The therapeutic value of the Roentgen rays is already well known, so that it is unnecessary to mention specifically the various forms of disease on which they exercise curative effects.

The whole of the apparatus herein described is housed on the top floor of one of the hospital buildings, which has been set apart wholly for this purpose. The circuits to the various cubicles are controlled by a large main switchboard, and connected with the main circuit of the hospital. We recently availed ourselves of an opportunity of inspecting the whole installation, and were exceedingly pleased to find how complete were the arrangements for applying the curative properties of electricity for the alleviation of so many of the diseases of suffering humanity.

ELECTRICITY LEAFLETS.

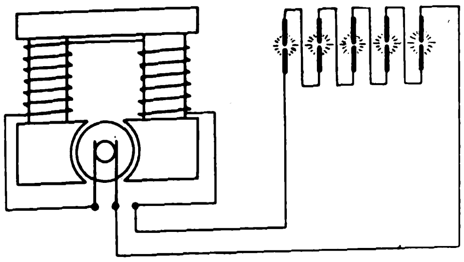
BY NEWTON HARRISON, E. E.

Electric Lighting.

Electric lighting has progressed with wonderful rapidity in the last decade. Totally distinct systems have become merged into one and currents which are either alternating or direct are transformed into each other without difficulty. Electric lighting proper and power transmission have become stepping stones to each other, so that the greatest operating systems found in New York and other of the largest cities in the United States embody these two ideas—a combination of high pressure alternating with low pressure direct—in the present equipment of electric light stations.

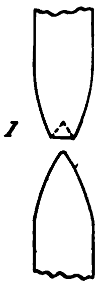
Kinds of Electric Lighting.—Electric lighting is done by means of alternating and direct currents. If the alternating current is solely employed for this purpose the machinery used includes alternators and transformers, the essential elements of this system. If direct current is used for electric lighting, the character of the current varies according to the nature of the lighting or lamps employed. Under the head of direct current lighting may be found: Lighting by means of a constant current, and lighting by means of a constant potential.

Dynamos suitable for the generation of such currents are also termed "constant current and constant potential dynamos." Constant current dynamos are designed for the purpose of supplying energy to arc lamps; constant potential dynamos for the purpose of supplying energy to incandescent lamps. A constant current dynamo is series wound, and in consequence the current developed in the armature passes through the outside series circuit, the field windings, back again to the armature. The illustration clearly shows the simple character of the system.

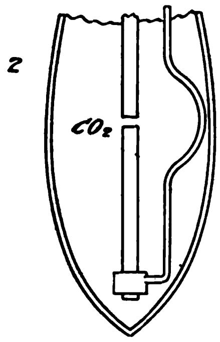


Series Wound Dynamo and Arc Lamps in Series.

In a series system of electric lighting each arc lamp requires a certain current and pressure or it will not give the candle power expected. The old type of arc lamp consumed 10 amperes and 50 volts; the new type with closed globe takes 80 volts and about 12 amperes. One lamp is built with its carbons burning in the air the other and more improved type has them inclosed in a small globe supplied with a valve. When the oxygen in the air is consumed only an innocuous gas remains. The result is no further oxidation of the carbons and an increase in their period of usefulness of from 8 or 10 hours in the older design to from 100 to 150 hours in the most improved design. The increase in power required through the introduction of this later device is well counterbalanced in a financial sense by the saving in labor in renovating the carbons, by the saving in carbons themselves and by the greater safety and convenience their use entails. These lamps are used on both the constant current, constant potential and alternating current systems.



Carbon lasts 10 hours in air.

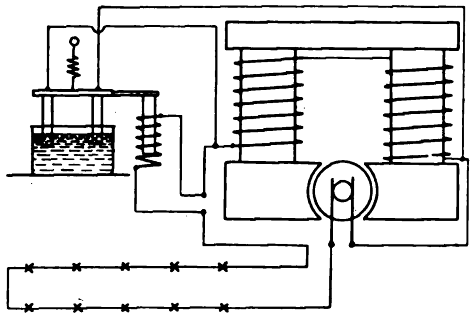


Carbon lasts 150 hours in a globe.

Constant Current Regulation.—Regulations by means of a series dynamo connected to a series circuit calls for a method by which the dynamo is capable of automatically increasing or decreasing its difference of potential as the number of lamps are increased or decreased in its circuit. If, for instance, 20 lamps of the older type were employed, each lamp requiring 50 volts and 10 amperes, a current of 10 amperes and 1,000 volts must be sustained. This is not all, however; the dynamo is furthermore required to automatically regulate its voltage and current if one-half or one-quarter of the lamps are cut off. This means that if 10 lamps are on the circuit 500 volts only are needed, 15 lamps, 750 volts, etc., and under all these circumstances of change the 10 amperes remain constant. The problem is that of a circuit in which, with every increase of resistance, an increase of voltage must take place. The accomplishment of this is due to a very interesting study of the conditions which prevail in a dynamo. The means to be employed for the regulation of the voltage of a dynamo can be included under the following heads: Increasing or decreasing the speed, increasing or decreasing the lines of force, and increasing or decreasing the armature conductors.

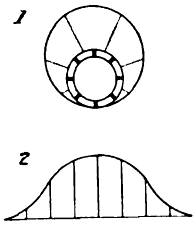
It is quite evident from a review of the possibilities presented here that it is not practical to attempt to change the speed to suit each particular voltage. The other two methods have been successfully carried out; that of varying the magnetic field by means of a resistance placed across the terminals of the field winding, so controlled in an automatic sense that when more volts were required this resistance was increased and when less volts were required it was cut down; and a utilization of more or less of the armature conductors as more or less lamps were thrown into circuit.

Shunting the Field.—The reasoning employed to utilize the changes in field strength is as follows: If more volts are required of the dynamo, more volts can be generated if more lines of force are supplied to the rotating conductors. The reverse is also true when less volts are required, due to the number of arc lamps being diminished. If an electro-magnet is placed in series with the outside circuit, a temporary increase or diminution of current caused for an instant by the lamps being increased or decreased in number, will make the coil a stronger or weaker electro-magnet. If the coil attracts a core of soft iron, which is attached by the proper mechanism to a pair of carbons dipping into water, then if the mechanism operates in such a manner that when the magnet is strengthened the carbons dip deeper and when the magnet is weaker the carbons are lifted out, the object is accomplished of weakening the field strength by shunting the fields when the pressure is too high outside, and increasing the field strength by lifting the carbons out when the outside pressure is too low. Tracing the circuits will show that the carbon rods dipping into the water offer a resistance which is greater or less across the field terminals according to the strength of the current in the main circuit. When the carbons dip deeply, current from the field passes through in such strength that the ampere turns are cut down and less volts are generated. When the carbons are lifted, less current passes through this liquid rheostat and more in the fields. In other words, this represents an adjustable resistance, adjusted in a shunt of greater or less resistance by the dynamo current, and this current itself temporarily varying through the effect of changes in the number of lamps of the circuit. To sum up, if the voltage supplied to a series of arc lamps is so elastic that more lamps means more volts and less lamps less volts, then as the increase or decrease of lamps mean the increase or decrease of ohms, the result would be a current of practically uniform strength. This, in fact, was the case with generators of this description, but the difficulty of adjusting the carbon rods and the resistance of the solution combined with a certain lack of responsiveness in the electro-magnet was the means of causing the general adoption of the last method of regulation by shifting the dynamo brushes.

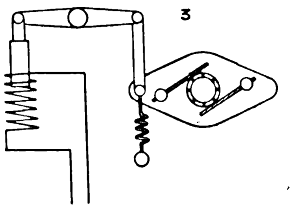


Regulating the Field Strength Automatically.

In reality, the conductors of an armature can only give out their full EMF. if the brushes are so situated on the commutator that their EMF. can be collected. There are points on the commutator where a pair of brushes can collect the maximum and minimum pressure. This is readily discovered in an ordinary shunt dynamo where the shifting of the brushes to different parts of the commutator increases or lowers the pressure a great many volts. Examination of the armature winding discloses the fact that the commutator is so connected to its conductor that the brushes can take off the pressure at a point where the EMF. is low as well as at a point where it is high. In fact, between points 90 degs. apart from each other, the commutator can give the highest and lowest pressure of the armature. The practical effect of this really is to increase or decrease the EMF. producing wires of the armature, at will. This cutting down or raising up of the armature difference of potential can be done by moving the rocker arm of the dynamo to which the brushes are attached either by hand or automatically. In arc light practice it is accomplished automatically by means of an electro-magnet connected to the main circuit. The current passing through the string of arc lamps actuates this coil and also a core which it energizes. The core is so arranged that it moves the rocker arm of the dynamo as the pull exercised upon it by the electro-magnet is greater or less. If the current in the magnet is very great the rocker arm is pulled over quite a distance, and in consequence the brushes take the pressure from different points of the commutator. When the magnet is not pulling very hard the current in the main circuit is normal, that is to say, an adjustment has taken place between the resistance represented by the arc lamps and the voltage supplied to the line by the dynamo. This continuous adjustment is only brought about effectually by means of an electro-magnet sensitive to a rise or fall of the normal current and its consequent reaction upon the position of the brushes through the medium of the rocker arm.



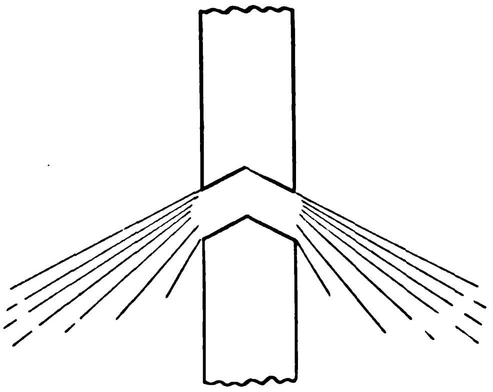
1 and 2—Distribution of Potential around a Commutator.



3—Shifting of Brushes by an Electro-magnet.

The preservation of a constant current in arc light circuits is only carried out if they represent the series high tension system. Here the voltage, as already shown, is calculated with reference to the number of lamps in operation, but arc lamps are constructed to work on low potential circuits as well by certain changes in their mechanism. In this case the preservation of a constant potential is necessary and the lamps are constructed and adjusted to suit the conditions.

Pressures as high as 6,000 volts have been used in high tension direct current lighting. The character of the current is pulsating, the throb or pulsation being very effective in keeping the high tension arc lamp mechanism in good adjustment. The candle power of arc lamps may be rated as either spherical or horizontal. The spherical candle power is the amount of light distributed on all sides of the arc. Light measured on a horizontal plane is the effective candle power produced. Means are employed to reflect as much of the candle power as possible downward and thus increase the effectiveness of the lamp as a source of illumination. In arc lamps used on alternating current circuits a reflector is absolutely necessary on account of the constant reversal of the arc. During one alternation the crater of the carbon is above, during the next below. The result of this is the continuous shifting of the light upward and downward and hence the necessity for a reflecting device of some description to preserve a uniformity in the degree of horizontal illumination.



Natural Reflector formed by the Crater in the Upper Carbon.

Constant Current Motors.—In those instances where other sources of electrical power are not available constant current motors are employed on high potential circuits. These motors are series wound and are regulated by means of their fields. The tendency of a series motor is to increase in speed if the load is reduced or the pressure increased. The regulation of this machine is accomplished by means of a governor, the action of which is to move a conducting piece along an insulating rod to which are attached one end of a series of coils composing the field winding. The field winding is divided up into a number of smaller coils which can be thrown in or out of circuit by the movement of the connecting piece actuated by the governor. If the speed of the motor tends to increase the governor by its action reduces the power of the machine by weakening the field. The operation of this device has nothing to do with the preservation of a constant current. That is attended to by the arc light generator and the current in the motor therefore remains the same.

The increase or decrease in the field strength or the shifting of the brushes of a constant current motor all accomplish the same thing, the preservation of a uniform speed with various loads and a correct adjustment between the power consumed by the motor and work to be done.

THE SUCCESSFUL JOINT UTILIZATION OF SEVERAL SMALL WATER POWERS.*

BY W. B. JACKSON.

At the present time it is probably not passing beyond the limits of truth to state that the electric current is the most important known transmitting, distributing and translating medium for power and light.

This high position in the arts has been attained only after tremendous struggles in solving the many problems required to make the electric current a suitable and reliable element for commercial use; and many of the most difficult problems yet remain to be solved.

I do not propose to solve these problems in this paper, but wish to present some interesting aspects of electrical construction and operation.

There are certain features in the transmission and utilization of electricity for the production of light and power which have become recognized as of paramount importance in successful commercial installations.

First—Absolute reliability of service.

Second—Uniformly good service.

Third—Economy of operation, including fixed charges.

A few years ago instantaneous or temporary cessations of the lighting and power service were taken more or less as a matter of course; to-day such irregularities are considered grave offenses.

Although it has not been long since the variations of pressure from the normal in distribution circuits might have been measured in fives, and even tens of per cent., without a thought; at present service furnished wherein this pressure variation exceeds two or three per cent. is subject to rightful criticism.

The necessity for the greatest possible economy in operation is more and more marked as the common use of electric current becomes more general, and greater competition enters into its production.

In planning and operating any electric light and power plant these features must be given the best consideration. It may usually be said that when the question of reliability has been solved good service follows as a matter of careful study of the conditions and making the necessary adjustments. These elements bear little or no direct relation to the matter of economical operation.

---

* Paper read at the 13th annual convention of the Northwestern Electrical Association, held at Milwaukee, Wis., Jan. 18-20, 1905.

At the present time a marked change is taking place with respect to the sources of power which are being utilized for transformation into the electric current.

Whereas, in times past, cities of from 20,000 to 30,000 inhabitants almost invariably received all the service needed from a single steam plant centrally located in the city; at the present time not a few of the cities of from 15,000 to 30,000 inhabitants are receiving their power and light from two or more electric plants, one or more of these being hydro-electric plants, capable of furnishing all of the electric service required during certain periods of the year and only a portion of it during the remaining time. This is even true of some of the smaller cities.

I have in mind a city of about 17,000 inhabitants, which has no less than three separate hydro-electric plants, two of these being provided with steam auxiliaries. This is the system of the Janesville Electric Company, of which one of our past presidents, Mr. P. H. Korst, is the manager, and in the details of which he takes an intimate interest.

This plant, like numerous others in our Western cities, started many years ago, when the town was young. Its growth was continuous with the town until it was operating about 130 hp. of water wheels and had an engine capacity of 350 hp., located in the center of the city.

About this time it had the opportunity to add to its available power, under favorable conditions, the Fulton hydro-electric plant, at a distance of about twelve miles from the central plant. In this transmission 3-phase alternating current at 60 cycles and 6,000 volts is generated from the power of the Yahara River.

It was not long before further power was required by the company, and it was again enabled to add to its resources another hydro-electric plant. This is its present Monterey plant, located about three miles south of the city, upon the Rock River. Here 350 hp. of water wheels and a 350 hp. engine have been changed from driving a cotton mill (their original sphere of action) to driving a 275 kw. alternating current generator, which furnishes 3-phase current at 60 cycles and 2,300 volts pressure.

Thus the electric company had acquired, step by step, a system comprising:

A centrally located hydro-electric plant with steam auxiliary, together with the requisite distributing circuits and translating devices.

A hydro-electric plant transmitting 3-phase, 6,000 volt alternating current, twelve miles to the central plant.

And a second hydro-electric plant with steam auxiliary, transmitting 3-phase, 2,200 volt electric current three miles to the central plant.

The distributing system comprises a 3 wire, 125 volt direct current service furnishing the lighting and power for the central section of the city; a 500 volt street railway circuit for operating the street railway of the city; 3-phase alternating current distributing circuits for furnishing light and power to the outlying districts of the city, and alternating current series arc lighting circuits.

As the central station had outgrown its quarters, and conditions made it undesirable to remain in its old location, it was decided to build a new plant at a point where a much better hydro-electric development could be accomplished, but still affording a centrally located plant for general distribution throughout the city.

The question then confronted the company of determining the best arrangement for the new plant so as to bring together in one united whole the several plants under their control, in order that they might give the most efficient and most satisfactory results in all of the several classes of service to be supplied by their system.

All of the apparatus in the old station was in excellent condition, but it was in small units. Nevertheless, it was decided to utilize practically all of it in the new plant, adding thereto only what was required to take care of the increasing load.

There are not infrequent cases when old apparatus is thrown aside in the reorganization of electric plants to be replaced by more modern and possibly slightly more efficient apparatus, when the actual added net returns from such a change are far less than the added fixed charges, and which, had the old apparatus been suitably continued in service, would have given thoroughly reliable and satisfactory results for many years to come at a positive net saving to the company.

Some of the details of the Janesville system should be of considerable interest to those concerned with the generation and utilization of electric current.

There are installed in the new central referred to 780 hp. of water wheels driving a single shaft extending through the building. This shaft is appropriately subdivided to permit operating portions of the plant while the others are at rest or undergoing repairs.

Belted to the shaft upon one side are the driving elements, comprising a 350 hp. Corliss engine and two synchronous motors, one for 6,000 volts, the other for 2,200 volts. All of the driven elements, comprising two 125 volt and three 250 volt 75 kw. direct current dynamos and one 110 kw. 500 volt dynamo, can be belted to the shaft from the other side.

Thus suitable space is obtained for all of the driving and driven machinery and at the same time the belt drive of each unit can be arranged to possess the advantages of having the lower belt upon the pulling side.

Although the usual work of the synchronous motors is to receive power from the other plants and assist the water wheels in driving the main shaft of the central plant, yet when desirable they are driven and used to supply the alternating current required for that portion of the lighting and power system.

By the use of transformers located between the 6,000 volt section and the 2,200 volt section of the switchboards, the 6,000 volt apparatus may be operated in connection with the 2,200 volt apparatus with practically the same facility as though everything was at one pressure.

The arrangement of the switchboard is simple, but affords the possibility of operating any one of the plants singly or in any combination with the other plants that the stage of the water may make desirable.

By the arrangement noted a thoroughly practicable and efficient combination is obtained whereby all of the power for supplying the entire service of the electric system may be drawn from any one of the three plants, and two of the plants are equipped so that the power may be furnished either by water or steam, as conditions warrant. An efficient combination of the several plants is thus accomplished and the company is remarkably well fortified against possible interruptions of service. Only a very unusual coincidence can simultaneously disable all the sources of supply.

The ability of the alternating current machine to operate either as generator or synchronous motor, without any changes in its connections or switching devices, becomes of great value in systems like that of the Janesville Electric Company, from the point of view of utility, as already referred to, and also from affording the effect of an equivalent amount of reserve apparatus, thus economizing in space and dispensing with extra driving gear and machinery.

There are not a few plants in operation to-day which might take advantage of this characteristic of alternating current machines to their benefit, but which have not done so. It is not necessary that the conditions of the system should be identical with those of the Janesville Electric Company to make this possible.

In canvassing the necessities of the new central plant it was seen that reserve capacity for the street railway service was highly desirable. This did not appear to be of sufficient moment to warrant the purchase and installation of apparatus which would have to lie idle during almost the entire time. It was therefore decided to add to the one 250 volt direct current dynamo which the company had in use two more like machines, so that any one or more of these could operate upon the three wire lighting and power circuits either in connection with two 125 volt direct current generators or in connection with a balancing set, or so that any two of the machines could be connected in series with each other and thus be used to furnish 500 volt current for the railway. This afforded reserve capacity for the railway while providing necessary machinery for the lighting service.

These two machines were arranged to accomplish this result by being furnished with double throw switches which, when thrown up, put the dynamos individually upon the lighting circuits, and, when thrown down, put the dynamos in series with each other upon the street railway circuits.

At present these dynamos are operated with very little compounding, and it is necessary to adjust their fields to keep the load properly divided when they are running in connection with the two compound wound 125 volt dynamos on the three wire system.

Mr. Korst proposes to have the connections of the series windings which are now on the machines rearranged so that one-half of the turns will be associated with each terminal of the dynamo. This will make it possible for these dynamos to be operated on the three wire system with the 125 volt dynamos and compounded to a corresponding degree.

I might add, that in building the new plant it was deemed advisable to construct the penstocks, forebay and retaining walls entirely of concrete, thus saving the unending repair and depreciation account so prominent in all timber construction used for such purposes.

Further, it was found that concrete blocks could be obtained under satisfactory conditions for the construction of the power house, and this is probably the first electric power house in the State built of these blocks. Thus, in the construction of the buildings, foundations and penstocks, everything between the roof sheathing and the lowest point in the water wheel discharge pits is either of steel, iron or concrete, except the windows and doors and the framing of the wheel house, which latter is covered with corrugated iron.

By bringing these three water powers together into a harmonious system the Janesville Electric Campany furnishes all of the electric light and electric power for the city of Janesville and vicinity as well as some electric light for the city of Edgerton, about 11 miles north of Janesville, almost entirely from water power. This nearly eliminates the use of coal in the operation of their plants.

The company maintains 850 hp. of steam auxiliaries for use in case of emergencies and at times of very low water, but experience shows that the hours of service for these will be few.

FUEL ECONOMY IN ELECTRIC GENERATING STATIONS.

(From our London Correspondent.)

There are few power plants in operation—however modern they may be—in which there does not exist the possibility of effecting numerous economies. Some of our engineers center their efforts upon one particular section of the system, and some upon another, being differently impressed as to the direction in which they can best obtain more economical efficiency. The model plant would be that in which all these ideas for economical working were adopted and giving good results. With a view to promoting a discussion in which engineers might talk of their practical experiences in such directions, a paper on "Fuel Economy in Steam Power Plants" was placed before the Institution of Electrical Engineers in London on January 12, by Messrs. W. H. Booth and J. B. C. Kershaw. In the main they devoted attention to the steam power economy which is to be secured by attention to fuel and its combustion, feed-water and its treatment and heating, furnace design and arrangement, and steam treatment and its use in suitable engines.

Fuel represents 50 per cent. of the total works cost in the generation of electricity, and it is held that from 10 to 20 per cent. of this outlay can be saved by engineers giving greater attention to the regular sampling and testing of fuel. It is too often thought that because fuel is cheap it may be wasted with impunity, but Messrs. Booth and Kershaw contend that much of the inefficiency to be found in the boiler houses of electricity works is to be traced to this fallacy. A check upon the colliery firm or coal merchant supplying the fuel is afforded by a laboratory examination, and this is useful not only in maintaining regularity in the quality of fuel supplied, but also in affording a basis for the new contracts which are, from time to time, made. Experts during the last few years have been continually showing that insufficient attention has been given to the question of adapting the furnace construction and methods of firing to the fuel; the recommendations of boiler makers have been too readily accepted. With suitable furnace construction and scientific control, bituminous fuels can be burnt without causing smoke troubles, and with high efficiency under every type of boiler, thus enabling great saving to be effected in the cost of fuel. But the furnace construction has to be adapted to the fuel, and it must not be supposed that furnaces designed for burning anthracite or semi-anthracite fuel will satisfactorily burn fuels containing 30 per cent. or more of volatile matter.

The correct and incorrect forms of construction for furnaces, the question of air supply, hand-firing versus mechanical stoking, losses by radiation, air leakage and condensation, the heat losses in waste gases, and other points, were all briefly touched upon. It was pointed out that the best results can only be attained if scientific methods of control are employed in relation to feed-water, fuel, waste gases and draught. Automatic apparatus for testing flue gases or any other product can never take the place of the trained chemist, for an automatic apparatus demands not less, but more, skill in its control and management than ordinary apparatus, if the records obtained by it are to be of permanent value. While automatic apparatus is of great service in enabling one skilled and efficient man to increase the number and extent of his duties, and practically to treble or quadruple his efficiency, it does not, and cannot, give accurate and valuable records when placed in the hands of untrained men. This applies to testing apparatus quite as much as to automatic stoking appliances, and the authors of the paper referred to argued that in the working of a modern boiler plant the chemist is as much in place as in a chemical works, and that the recognition of this truth would undoubtedly promote the economical working of such plants.

The benefits to be obtained from the use of durable and efficient storage batteries in combination with lighting and traction generating stations were touched upon. The fullest economy of first cost, and more especially of running cost, are recognized by all station engineers as only obtainable, in the present state of knowledge, by means of a battery, but the fact that the battery is so far from perfect still renders its adoption in any case a matter of grave and careful deliberation.

Proposals Invited.

The Bureau of Supplies and Accounts of the Navy Department is inviting sealed proposals until February 21 for furnishing the navy yards at Boston, New York, League Island, Washington and elsewhere with the following: Schedule 72, arc lamps, rubber covered wire and electrical supplies; schedule 75, cable, battery cells, electric equipments for ammunition hoists; schedule 76, magnet wire, cable, incandescent lamps, mica, electric blowers and electrical supplies. Blank proposals will be furnished upon application to the navy pay offices in the cities mentioned, or to the Bureau. Applications should designate the schedule desired by number.

The Treasury Department, through the Bureau of Printing and Engraving, is inviting sealed proposals until April 11, for furnishing the Bureau with a quantity of electrical supplies during the next fiscal year. Specifications and proposal blanks can be obtained upon application to W. M. Meredith, Director of the Bureau, Washingtnn, D. C.

A Valuable Cyclopedia.

The "Cyclopedia of Applied Electricity" is published in five volumes containing about 2,500 pages and over 3,000 illustrations. It is bound in three-quarters red leather. The list price is $30; special introductory price $18. Published by the American School of Correspondence, at the Armour Institute of Technology, Chicago.

This work is the most comprehensive work on electricity and its practical applications that has yet been published and will prove invaluable to electricians, engineers, telephone and telegraph operators, engineering students, and any person who has occasion to use electricity in any form. To be able to turn quickly to any phase of electricity as used in our great industries is of immense value to both the busy practical man and the engineering student. In these volumes the reader finds a treatment of the latest developments of electricity by acknowledged authorities, fully indexed, and written in a simple, direct way, free from difficult mathematics especially adapted to the needs of the busy practical man.

The work is not addressed to the technically educated specialist, and for this reason all of the descriptions and explanations which it contains have been simplified to the utmost possible degree consistent with a thorough presentation of the subjects treated. Higher mathematics have been entirely omitted, and the subject matter of the work is explained in simple lauguage in connection with a large number of diagrams prepared especially for the text. The halftone engravings are of special value as they illustrate all of the electrical machines and apparatus made by the prominent electrical companies in the United States and therefore acquaint the reader with the types of apparatus used in current engineering practice.

The usefulness of the cyclopedia as a reference book is augmented by the addition of a subject index contained in the fifth volume. The practical value of the work as a whole can hardly be questioned as the cyclopedia embodies the various electrical courses which have been successfully used by the American School of Correspondence in teaching thousands of electricians. The work is, in fact, the outcome of a most successful method for the education of the busy man. It will be found of the greatest value to designers, constructors and operators of electrical machinery, and as it is the only textbook and reference work covering every department of electricity thoroughly, its use will save many valuable hours of search among scattered text-books on electricity.

Appleton Electric Company's Catalogue.

A new catalogue has just been issued by the Appleton Electric Company, 224 Washington Street, Chicago. This enterprising concern carries among other things a complete line of electric lighting and telephone supplies and Marlin cable hangers. A catalogue may be had by addressing the company as above.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED JAN. 31, 1905.

Electric Railways and Appliances.

781,116. Motor Car. John Wilkinson, Syracuse, N. Y., assignor to the H. H. Franklin Manufacturing Company, same place. Filed May 17, 1904.

781,268. Underground or Conduit System for Electric Railways. William Cope, Birmingham, Eng. Filed May 24, 1904.

781,316. Guard and Finder for Trolley-Poles. William P. Underhill, Brooklyn, N. Y. Filed May 21, 1904.

781,359. Trolley. Leonard O. Pullen, Augusta, Me., assignor of one-half to Thomas J. Lynch, same place. Filed March 26, 1904.

781,404. Trolley-Pole Support. Thomas J. Cope, Philadelphia, Pa. Filed Oct. 29, 1904.

781,431. Electric-Railway System. Frank E. Kinsman, Plainfield, N.J. Filed Dec. 8, 1903.

781,572-573. Traction-Wheel. Marquis J. Todd, Buffalo, N. Y., assignor to the Buffalo Pitts Company. Filed April 21 and May 9, 1904.

Electric Lights and Appliances.

780,997-781,606. Apparatus for and Method of Producing Oscillatory Currents. Peter C. Hewitt, New York City, assignor to the Cooper Hewitt Electric Company. Original application filed Feb. 9, 1903. Divided and last application filed July 28, 1904.

780,998. Apparatus and Circuits for Starting Electric Lamps. Peter C. Hewitt, New York City, assignor, by mesne assignments, to the Cooper Hewitt Electric Company. Filed April 5, 1900.

780,999-781,000-781,603. Method of and Apparatus for Transforming Electrical Energy. Peter C. Hewitt, New York City, assignor, by mesne assignments, to the Cooper Hewitt Electric Company. Original application filed April 25, 1902. Divided and last application filed Sept. 24, 1902.

781,001-002. Means for and Method of Amplifying Electrical Variations. Peter C. Hewitt, New York City, assignor, by mesne assignments, to the Cooper Hewitt Electric Company. Filed May 16, 1902.

781,016. Incandescent Lamp. Almon D. Page, Newark, N.J., assignor to the General Electric Company. Filed March 18, 1904.

781,226. Incandescent-Lamp Socket. Walter H. Perkins, Waterbury, Conn., assignor to the Waterbury Mfg. Company. Filed Oct. 31, 1904.

781,351. Electric-Lamp Socket. Mortimer Norden, New York City, assignor to Joseph Norden, same place. Filed March 9, 1904.

781,605. Method of Producing Light. Peter C. Hewitt, New York City, assignor to the Cooper Hewitt Electric Company. Original application filed April 25, 1902. Divided and this application filed July 1, 1904.

Electrical Machinery and Apparatus

781,008. Electric Motor. Michel Koener, Chicago, Ill. Filed May 18, 1904.

781,022. Turbine-Wheel Construction. Richard H. Rice, Lynn, Mass., assignor to the General Electric Company. Filed July 22, 1904.

781,035. Commutation of Electric Currents. Elihu Thomson, Swampscott, Mass., assignor to the General Electric Company. Filed Sept. 17, 1903.

781,134. Interlocking Device for Controllers. Edward H. Dewson, Edgewood Park, Pa., assignor to the Westinghouse Traction Brake Company. Filed June 9, 1903.

781,154. Method of Controlling the Running of Reciprocating Engines or Turbines Driving Alternators in Parallel. Charles A. Parsons, Newcastle-upon-Tyne, and James Swinburne, London, Eng.; said Swinburne assignor to said Parsons. Filed March 30, 1903.

781,307. Transmission-Gearing for Motor-Vehicles. Charles Schmidt, Warren, O., assignor to the Packard Motor Car Company, same place. Filed June 22, 1903.

781,339. Electric Time-Switch. Jacob Helmstadter, Jr., McKeesport, Pa. Filed Dec. 11, 1903.

781,340. Transformer Cut-out. John P. Hetherington and Lewis E. Grubbs, Logansport, Ind.; said Grubbs assignor to said Hetherington. Filed Dec. 28, 1903.

Telephones and Telephone Apparatus.

781,207. Telephone-Relay. William W. Jacques, Boston, Mass. Filed Nov. 3, 1904.

781,225. Rent-Collecting Means for Telephone Service. Joseph L. Peavey, Meridian, Miss. Filed Jan. 15, 1904.

781,237. Telephone System. Charles B. Smith, New York City. Filed Feb. 23, 1901. Renewed Oct. 22, 1902.

781,625. Method of Protecting Telephone-Circuits from the Action of Electromagnetic Waves. John S. Stone, Cambridge, Mass. Filed June 29, 1904.

Miscellaneous.

781,062. Electrical Tool. David J. Hauss and Casper W. Miles, Cincinnati, O., assignors to the Cincinnati Electrical Tool Company. Filed April 24, 1903.

781,077. Electromagnetic Ore-Separator. Erich Langguth, Euskirchen, Germany. Filed Feb. 1, 1904.

781,194. Automatic Code-Ringer for Magneto Signal-Bells. Larkin V. Elliott, Indianapolis, Ind. Filed Feb. 20, 1904.

781,288-289-290. Thermo-Electric Element. Albert L. Marsh, Lake Bluff, Ill., assignor to William A. Spinks & Co., Chicago, Ill. Filed Oct. 18, 1904.

781,319-320-321-322. Signal System. Claude White, St. Louis, Mo., assignor of one-half to Charles T. Noland, same place. Filed Feb. 2 and Aug. 27, 1904.

781,353. Conduit for Electric Wires. Stephen Palmer, Troy, N. Y., assignor to Marcus M. Waterman, James K. P. Pine, James J. Child, Herbert E. Northrup and George W. Daw, same place. Filed Nov. 17, 1903.

781,416-417-418. Electric Telegraph. Willis D. Gregory, Pittsburg, Pa. Filed March 30, 1904.

781,448. Electromagnetic Apparatus. John McIntyre, Jersey City, N. J. Filed Oct. 29, 1904.

THE TELEPHONE WORLD.

Telephone War Expected.

Port Byron, N. Y., promises to be the center of a lively telephone war between the Bell and the Independent interests. For years the Bell people have had the only service available. The new Port Byron Company is already an assured success. The directors are canvassing not only in Port Byron, but Throop, Montezuma, Conquest, Spring Lake and Emerson.

To meet this threatened invasion the Empire State Telephone (Bell) Company has started out on a systematic canvass of that territory. promising to build rural lines and to give cheap rentals, but the farmers believe that they can build and operate their own lines cheaper than they can hire.

A large delegation representing the directors of the new Independent company recently went over to Emerson and the trip resulted in enough new subscribers to build the line to Emerson and Conquest.

The Port Byron Company stands ready to build to Weedsport and establish an exchange there in opposition to the old company

The organization of the Volney Telephone Company in Fulton, N. Y., has been completed with the following officers: President, Robert Simpson, Jr.; vice-president, C. B. Sackett; secretary, Eugene Rowe; treasurer, E. E. Hart. The purpose of the company is to supply telephone service to the farming neighborhood, and the system will co-operate with the Ontario Telephone Company.

Articles of incorporation of the Waitsburg, Wash., Rural Telephone Company, with a capital stock of $10,000, have been filed. The incorporators are all Waitsburg men. The company has control of all the rural telephone lines in the counties of Walla Walla and Columbia and will establish an exchange at Waitsburg.

At the annual meeting of the Barton, Vt., Telephone Exchange Company the following officers were elected: President, H. J. Stannard; manager, E. S. Colliston; secretary, J. N. Webster; committee on admission, M. M. Scott, E. W. Barton and F. W. Baldwin.

The Concord, Neb., Farmers & Merchants' Telephone Company has been organized and has filed articles of incorporation with the Secretary of State. The new company has a capital stock of $10,000.

Chatfield, O., citizens have organized an Independent telephone company and will build a line to connect with the toll lines through Crawford County. The work of construction will begin as soon as the weather will permit.

The directors of the Consolidated Telephone Companies of Pennsylvania recently met in Allentown and elected Hon. R. E. Wright as president.

The Mutual Telephone Company of Rowena, Mo., has arranged to build a telephone line om Rowena to Centralia.

There were 32 Independent telephone corpotions organized in Wisconsin and capitalized at $500,000 during 1904.

Will Fight Bell Company.

Hundreds of Mt. Clemens, Mich., citizens attended the meeting called by the Business Men's Association in the Chamber of Commerce Hall recently to consider the action of the Michigan Telephone Company in raising its rates.

Formerly $12 was charged for residence service and $24 for business houses. Canvassers have been at work for some time and have demanded that all future contracts shall call for $30 for business places, $24 for homes and $18 for two-party lines. A committee has been appointed to see President W. A. Jackson.

If a promise is not secured that the rates will remain as heretofore, a new company to be known as the Macomb County Telephone Company will be organized by Mt. Clemens citizens.

The big telephone deal reported from Pittsburg, Pa., including a combination of 43 of the largest telephone companies in the country, and referred to in the issue of ELECTRICITY of February 1, has been denied by H. S. Howe, a director of the American Telephone & Telegraph Company, who says that "there is absolutely no truth in the report from Pittsburg that a telephone 'trust' is under way." Representatives of the trust have a way of denying everything.

The State of Sinaloa, in Mexico, through Governor Canedo, has granted an important concession to the Culiacan Electric Company, composed of Americans, which was recently organized with a capital stock of $300,000, for the construction and operation of long-distance telephone lines throughout the State and the establishment of local telephone exchanges at Culiacan and Mazatlan.

A joint meeting of the five telephone companies in Phillips County, Col., recently held a meeting in Holyoke, with John Heginbotham as chairman and C. E. Olmsted as secretary, for the purpose of organizing the five companies into one and putting in a central office at Holyoke with a modern switchboard

The contract for 100 telephones used by the United Railways & Electric Company was awarded by the executive committee to the Maryland Telephone & Telegraph Company after a sharp contest. The service will be connected with the largest private branch in the Baltimore telephone service.

The Independent Telephone Company of Plattsmouth, Neb., is showing a great deal of activity in Havelock. It is also building a line between Havelock and Prairie Home.

The higher officials of the Cumberland Telephone Company have under consideration petitions for the installation of a long-distance telephone service between Hattiesburg, Miss., and Jackson, La.

Charles S. Gleed of Topeka has been chosen president of the Missouri & Kansas Telephone Company, to succeed Alonzo Burt.

Independent telephone systems are now being installed in Green Bay and Depere, Wis.

Sale of Telephone Property.

The Augusta, Ga., Telephone & Electric Company's property will probably be bought, when put up for sale at the public sales in March, by a large Western corporation, who will add to the plant extensively, and operate it with much improved conditions.

It was agreed by all parties that the telephone properties be sold at the public sales, and a minimum price of $25,000 be placed on the property. It is also said that the stockholders will buy in the property.

Archibald Blackshear is receiver for the company and L. C. Hayne represents a large portion of the creditors.

The completion of the long-distance telephone line now being built to connect Denver with Omaha and Kansas City will give telephone users a transcontinental service and intercommunication with more than 2,000,000 subscribers. Denver is already connected with San Francisco, and thus a through circuit from New York to the Golden Gate will probably be established.

Terms of the reorganization of the Mexican Telephone Company are announced. According to the plan stockholders will be offered one share of preferred and two shares of common for every nine shares of the present stock. Bonds are offered at 97½ and interest. For additional work $200,000 is required.

The Hastings, Neb., Independent Telephone Company will, as soon as the ground thaws, begin the grading for its new building. This company now has over 110 stockholders, representing over $40,000 worth of stock, and by next year expects to have in operation in Hastings one of the finest plants in the State.

The city council of Mill Creek I. T., has finally passed an ordinance granting a 20-year franchise to the Sulphur Telephone Company to construct and maintain an exchange at that place. It must be in operation within 90 days.

The office of the Corporation Counsel of New York has started an examination of the charters and franchises of the telephone companies as a part of the campaign to compel the companies to make uniform charges for calls between the various boroughs and to put the wires under ground as required by law.

The National Telephone & Electric Company of Clinton, Ill., has purchased the Clinton, Waynesville, Farmer City, Wapella, Weldon, Mansfield and Dewitt exchanges and a number of farmer lines in Macon, Piatt, Dewitt, Champaign, McLean and Logan Counties for $100,000.

The Nebraska Telephone Company has begun work on a new line running east of Beatrice. It is to be a full party line and will be of great convenience to the farming community east of Beatrice.

Blackshear, Ga., will in a very short time have the service of a first-class telephone system.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Cadiz, Ky.—The construction of an electric light plant here is contemplated by A. R. White.

Canastota, N. Y.—A committee has been appointed by the Canastota Business Men's Association to investigate the feasibility of establishing a municipal electric light plant. A. A. Kessler is chairman of the committee and E. Saltsman secretary.

Chestertown, Md.—This town has granted a 40-year franchise to D. S. Pindell of Sault Ste Marie, Mich., to erect and operate an electric light plant.

Clarinda, Ia.—A franchise for the erection of an electric light, heat and power plant here has been granted to the Lee Electric Light Company. C. W. Stuart, city clerk.

Graceville, Fla.—The Graceville Electric Light & Water Company has secured a franchise to operate an electric light plant and construction will shortly begin.

Houlton, Me.—The Houlton Electric Light & Power Company, with a capital of $10,000, has been incorporated by H. T. Frisbee, president, and others.

Huntingdon, Tenn.—The city electric light and waterworks plant is said to have been leased by W. J. Holman, who will make improvements and operate it.

Lorain, O.—This city has decided to purchase the necessary machinery for the installation of a small electric light plant at the pumping station.

Lufkin, Tex.—The Lufkin Electric Light & Power Company, capitalized at $30,000, has been incorporated by S. W. Henderson, G. A. Hackney and others.

Morris, Ill.—The Electric Light Company is planning extensive additions and improvements to its plant on Illinois avenue.

Ogdensburg, N. Y.—A movement has been started toward the equipment of local electric light plants for several hotels and large buildings.

Osceola, Ia.—The light plant here will be enlarged and a hot water plant and day electric power are to be put in.

Renovo, Pa.—Joseph P. Kane of this city has secured the contract for lighting the streets with electricity, and will immediately commence the construction of a municipal and commercial electric lighting plant.

Rome, Ga.—A committee has been appointed by the mayor to prepare a bill to be presented at the next session of the Legislature authorizing this city to build and operate an electric light plant. Its cost will be about $20,000 to build and equip the plant.

Thomson, Ga.—The electric light plant for this city, that has been in course of construction for the past three months, is nearing completion, and it is now thought that by the first of March this place will be illuminated by electricity.

Uniontown, Ala.—This city will build a new and larger waterworks and electric light plant. Thomas Hudson, city clerk.

Willard, Utah.—At a mass meeting of the citizens held lately it was unanimously decided to take steps toward obtaining from Brigham City electricity sufficient to furnish this place the desired power and light necessary.

STREET RAILWAYS.

Auburn, N. Y.—The Auburn & Syracuse Electric Railway Company has purchased the right of way over land owned by the Nelson Beardsley estate in this city, Sennett and Throop. According to the terms of the agreement all electric wires must be kept at least 20 feet from the ground.

Belleville, Mich.—The Michigan Central Railway Company has been granted a franchise to construct and maintain an electric railway.

Clarkston Mich.—The Owosso & Pontiac Electric Railway Company has been granted a franchise to enter this village.

Elgin, Ill.—An electric line will be extended from this city to Wing Park. Mr. Wolf is president of the company.

Fullerton, Cal.—The Pacific Electric Company has been granted a franchise for the right of way for electric lines in this city and cities near by.

Harrodsburg, Ky.—An electric railway will be built between here and Burgin.

Johnstown, N. Y.—A mortgage of $1,750,000 has been given by the Eastern New York Railroad Company to the Metropolitan Trust Company. This is to secure the issue of 5 per cent. bonds of a like amount. The company will build electric railroads from Ballston, N. Y., to this city, Gloversville and Amsterdam.

McKinney, Tex.—A special meeting of the city council was held here recently and a franchise granted for the construction of the tracks of the McKinney-Bonham electric line and operation of the interurban cars within the city limits.

Montreal, Can.—The Ottawa River Railway Company has awarded a contract to M. P. McGrath of Easton, Pa., for the construction of an electric line between Montreal and Ottawa.

Paterson, N. J.—The New York & New Jersey Rapid Transit Company has been organized for the construction next summer of an electric railroad, operated by the third-rail system, which will run from this city to Weehawken, and which, it is expected, will eventually be connected with one of the tunnels in Manhattan. The line, which will be about 14 miles long, will be elevated a large part of the way. The running time between the terminals will be about 20 minutes.

San Marcos, Tex.—A company to construct an electric line from this city to Luling has been organized here.

Standish, Mich.—There is talk of starting an electric road here and connecting this town with Sterling, Alger, Maple Ridge, Melton and Turner.

Uhrichsville, O.—There is talk of an electric railway from here to connect with the contemplated Barnesville and Woodsfield road. It is reported that Canton capitalists are interesting themselves in the project.

Utica, N. Y.—Paul Smith is building the first Adirondack trolley line through a wooded mountainous district. The line will extend to Paul Smith's from Lake Clear Junction, a distance of 19 miles.

Washington, D. C.—One of the largest electric railway projects of the country, which will have this city and Cleveland, O., as terminals, is attracting much attention here. George T. Bishop and Frank H. Gunn of Cleveland have interested capitalists there and elsewhere in the road, and control of the franchises of the uncompleted Washington, Annapolis & Baltimore Electric Road has been secured. This line will be double-tracked to Baltimore. From that city to Cleveland 57 per cent. of the route has already been graded. Construction will begin this spring.

Winona, Ind.—It is reported that the Winona Interurban Railroad Company will erect a power plant to cost, including machinery, $600 000, for furnishing the power for the various proposed electric lines. Sargent & Lundy of Chicago are the engineers.

POWER PLANTS.

Birmingham, Ala.—J. A. Emery, general manager for the Birmingham Railway, Light & Power Company, who has lately returned from New York, where he had been in conference with the majority stockholders of the company and the chief engineers, Ford, Bacon and Davis, announces that the company will during the present year spend a large sum of money on improvements throughout its system of light, heat and power plants in this city. Approximately the sum of $200,000 will be expended in improving the storage bins and making other improvements at the power house.

Wilmington, Del.—Plans for the erection of a power plant to supply light, heat and power for the Pennsylvania Railway Company's new office building and passenger station are being prepared by William H. Cookman, engineer.

BIDS WANTED.

Baltimore, Md.—The Steiner Mantel Company, 8th street and Fairmount avenue, this city, is in the market for electrical equipment and supplies.

Columbia, Va.—Charles Willard & Son want a second-hand small dynamo in good order, capacity 10 to 20 lights, 110 volts.

Cotton Plant, Ark.—The Moore & Priddy Printing Company of this place is in the market for one dynamo, with incandescent lights complete, and wiring.

Delray, Fla.—The Fruit and Vegetable Growers' Association of this city wants prices on one 30 hp. and one 15 hp. engine and two 30 hp. boilers, about 5 x 16.

Drice, Tenn.—H. Davis & Son of this place want catalogues and estimates on equipment for a furniture factory to be driven by an electric power plant.

Jacksonville, Fla.—Rev. J. T. Boone of this city wants prices on electric fixtures.

Knoxville, Tenn.—The Proctor Furniture Company, of which J. C. Sterchi is general manager, is in the market for a 100 hp. engine and 80 hp. boiler.

Norfolk, Va.—The T. W. Worsham Company is in the market for a 100 hp. boiler.

Statesville, N. C.—J. C. Steele & Sons are in the market for storage batteries, 125 volts, that will run fifteen 16 cp. incandescent lights 10 hours on one charge.

Warwick, Ga.—John F. Wise of this city wants a 60 to 70 hp. boiler.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 15⅛@15¼c.; Lake 15¼@15⅜c.; casting, 14⅞@15c.

Stockholders of the National Carbon Company will hold their annual meeting at Trenton, N. J., February 27.

Interborough Rapid Transit of New York on Monday made a sensational rise of 14 points, creating a new high record.

The directors of the Brooklyn Rapid Transit Company organized for the year by re-electing the retiring officials.

A member of the executive committee of the Electric Company of America says the new stock issue will not be put out for some weeks.

At the annual meeting on Monday of the stockholders of the Detroit Edison Company the retiring board of directors was re-elected.

The American Telegraph & Cable Company will pay the quarterly dividend of 1¼ per cent. on March 1. Books close February 13 and reopen March 1.

William McKenzie, of Toronto, Canada, with other associates, have arranged for the purchase of the concession for electric car lines for Monterey, Mexico.

There were sharp advances on Monday in Manhattan Railway and Brooklyn Rapid Transit. Third Avenue Railroad was in unusual demand at a material gain.

The annual meeting of the stockholders of the Milwaukee Electric Railway & Light Company will be held at the office of the company in Milwaukee, Wis., February 20.

Senator Minturn, of Hoboken, introduced a bill in the New Jersey Senate Monday night designed to remedy existing evils in the corporation law and drive all corporations not honestly promoted out of the State.

A resolution has been submitted to the Connecticut General Assembly to empower the Hartford & Springfield Street Railway Company to increase its capital stock from $500,000 to $1,000,000. This stock is controlled by Tucker, Anthony & Co.

Fully $25,000,000 was paid out on Friday last to stock holders of the Chicago City Railway Company. It was said to be the largest practically cash transaction ever carried through in Chicago. Something more than 124,000 shares of stock were paid for.

Wall Street is flooded with rumors to the effect that the Metropolitan Street Railway crowd, having failed to sell their road to the New York Subway people, have determined to get possession of that property in order to carry out a merger of all traction companies on Manhattan Island.

The Stanley Electric Manufacturing Company and the General Incandescent Arc Light Company, constituent companies of the General Electric Company, have been consolidated under the name of the Stanley-G. L. Electric Manufacturing Company. All the manufacturing will be done in the present works of the Stanley Company at Pittsfield, Mass.

At the annual meeting of the Western Electric Company, C. S. Holt, C. G. Dubois and J. W. Johnston were retired from the board and were succeeded by Charles Williams, Jr., Charles W. Amory and Thomas Sherwin. The treasurer reported that the total sales for the fiscal year ended November 30 were $32,454,000, as compared with $30,256,000 the previous year, a gain of 7.2 per cent. Net earnings are not yet known owing to delay in reports from foreign companies, but will be materially less than in the previous year.

EDITORIAL NOTES.

Valuable Data on South American Countries.

It cannot be denied that English and German electrical manufacturers cater far more to foreign markets than do the large concerns in this country. This may possibly be due to the fact that the home demand for electrical machinery in the two foreign countries mentioned above is not so great as in the United States, and consequently foreign markets have to be exploited in order to keep the plants running to their full capacity. This would seem a reasonable explanation, for it is hard to believe, and something we are unwilling to admit, that English and German firms have more "goaheadativeness" and enterprise than those on this side of the Atlantic.

And yet the fact remains that at the present time an examination of statistics on electrical imports to South American countries shows that almost without exception England and Germany are far in the lead of the United States.

A perusal of the article elsewhere in this issue, entitled "South American Trade—Exports and Duties," points out several reasons for this. The conditions in Mexico, Costa Rico, Nicaragua, Panama, Salvador, Argentine, Bolivia, Brazil, Chile, Columbia, Ecuador, Paraguay, Peru and Venezuela are touched upon and for each country the duties on electrical machinery and apparatus are given.

To electrical manufacturers or dealers, who are now exporting to any of these countries or who contemplate shipping goods to South America, the information contained in the article in question should prove valuable, and if for no other reason, this issue of ELECTRICITY should be carefully filed away near at hand as a ready means of reference.

* * *

Why Japan is a Marvel in Technical Progress.

No more astounding case has arisen in modern history than that of a nation classed as semi-barbarous leaping in one swift bound to the apex of technical excellence. Japan, an island nation, the subject for comic operas, tea house pictures and a certain class of literature depicting life as an abandonment to a lotus-like existence, has suddenly appeared as a grim warrior, armed with the most modern of armaments and possessing the intellect and tenacity of purpose that would do justice to the most advanced of civilized powers. Certainly this sudden transformation, this stupendous and unanticipated change is due to causes which must be vital in the affairs of any race. It is not that we, of the western world, have refused to believe in the intellectual capacity of those living within the confines of the Orient, but we have accustomed ourselves to the belief that China and Japan were alike—that such progress as we measure out to ourselves in our arts, our literature and our science cannot be attained by other than those of the Caucasian blood.

It is here that the mistake was made—and whether it can be explained by international conceit or an inability to fathom the depths of the oriental nature—the glaring fact remains that Japan has taken her place among the great powers of the world as an equal in the arts, in literature, in science, and most emphatically in naval and military warfare. Thirty years ago, when Russia with one wave of her mailed hand swept away the protestations of the Japanese and seized the island of Saghalien, Japan preserved a discreet silence, but she recognized the source of European strength and in her wisdom began the reconstruction of Japan. She sent her ablest young men far and wide to study these sources of power. The naval and military academies and the university departments of science found their full quota. She skimmed the cream of European knowledge and used it as the first chapter of that vast new volume, modernized Japan. The advantages are obvious. We, of the western world, have slowly toiled ahead, by cutting loose from the retarding influences of a conservatism as deeply rooted as that of the Orient. In our schools and colleges the past has woven its insidious web and as a result, the old-fashioned and time-worn methods of one, two and three centuries ago still to some extent prevail. The Japanese students, free from such bonds, came to the leading universities, colleges and schools. In these they found the knowledge for which they sought. And they took it back to fresh soil, to their own people as yet untouched by European educational influences. This is the reason why Japan within a period of 30 years became a civilized nation. She received her knowledge untrammeled by any older school. Her general progress is not based upon any precedent. She seized upon all that was best and assimilated it. In chemistry, in mechanics, in electricity and in medicine her sons have already made themselves famous. If it is true that the power of discrimination, as our philosophers state, is the highest measure of human intelligence, then in selecting the knowledge best suited to their needs—technical knowledge—the Japanese have shown themselves well worthy of the front rank in the advance guard of human progress.

* * *

A Warning to Bidders. Electrical firms may be interested to learn that the Navy Department has just called attention to the fact that bidders who submit proposals to the Bureau of Supplies and Accounts should be careful to send them in duplicate. Failure to meet this requirement will be regarded as sufficient reason for declaring the bids informal and bidders will run the risk of the loss of the contract.

Attention has also been invited to the fact that bidders who find they have made mistakes in their proposals will run the risk of being required to pay a penalty if they do not execute the contract when it is awarded. In several instances the lowest bidders have discovered they made errors in calculations, and they have asked to be excused from carrying out the contract. When the bids are close, and it may properly be questioned whether an error is excusable, the Navy Department will award the contract on the basis of the original bid. Failure to execute the contract will lead to the payment by the bidder of a sum representing the difference between his own bid and the next lower bid. This will protect the Government. Several instances of this kind have occurred lately, and it is now announced as a policy that the lowest bidder will not find it easy to withdraw his proposal when he learns he has really got the contract. If he refuses to abide by such a decision he will be transferred to the list of those firms that do not have the confidence of the Navy Department in such transactions. It therefore behooves electrical firms to exercise the utmost care in making their calculations, in order to obviate such a difficulty.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

If you have electrical machinery and apparatus for sale examine the Proposals Invited on page 99 of this issue.

◆

The officers of the Iowa Electrical Association have completed arrangements for the fifth annual convention which will be held at the Julien House, Dubuque, April 19 and 20.

◆

The first private wireless telegraph system in this country was put into operation last week at the Schenectady plant of the General Electric Company, and when the station at the Lynn, Mass., plant is completed the company will discontinue all private wires.

◆

A contributor to "Public Works," an English publication, states that the only way canal companies in Great Britain can successfully compete with their rivals is to drain the canals and convert them into electric railways. If canals are a thing of the past and bad investments, why is so much of the people's money being spent on the canals in New York State?

◆

Great interest has been excited among motorists by the report of the trial on the Seine in France of a new kind of motor boat, which is propelled by a 14 hp. De Dion-Bouton motor. The peculiarity of this boat is that the principle of the aeroplane is applied to it, and that it practically glides on the surface of the water instead of through it. The boat in question is about 20 feet long and about half that in width. On the bottom are fixed inclined planes or fins, the angles of which increase as they near the stern. When the boat is at rest it floats, more or less immersed, as an ordinary raft would do; but when under power the bow lifts out of the water and the boat glides along on the inclined planes. It is reported that at the trial the speed over a measured course was at the rate of nearly 20 miles an hour, which is about double the pace that could be got out of an ordinary launch with that power of engine. The boat is fitted with two rudders, between which the propeller works.

◆

The first telephone exchange in England was opened in London in 1879 with 10 subscribers. In 1888 London had 4,900 subscribers, while at the present time there are 100,000 'phones in use. This is 54,000 less than in this city.

◆

The craze for using garbage as fuel for producing steam wherewith to generate electricity for lighting is spreading. Columbus, O., now has the fever, but the city fathers should bear in mind that coal will still have to be purchased, for statistics go to prove that about one-third of the total bulk of this low grade fuel will have to be good anthracite coal, otherwise the fires will go out.

◆

A foreign paper states that the overproduction of trained engineers is causing much alarm in the profession in Berlin, Germany. The competition, it is stated, has become so keen that fully qualified engineers, equipped with the finest training the best technical universities of modern times can give them, are glad to accept appointments with a salary of $25 to $35 a month. The latest proposal is that all university-trained engineers should organize, and by united action make sure of at least a minimum "living wage."

◆

The "Zeitschrift fur Elektrotechnik" of Vienna states that a boat has recently been put into service on the Lake of Geneva, Switzerland, which is driven ordinarily by a 45 hp Diesel engine, running at 260 revolutions per minute, but electric power is made use of at starting and for reversing. The Diesel engine is directly coupled to a dynamo and a small exciter on the one side, while there is a magnetic coupling on the other side through which it can be connected directly to the propeller shaft. An electric motor is also provided, the motor armature being keyed on to the propeller shaft. At starting the Diesel engine is disconnected from the propeller shaft, and drives only the generator and the exciter. The motor is now switched on and its torque and speed are adjusted by regulating the excitation. When full speed has been attained in this way, the motor is switched off and the Diesel engine is directly coupled to the propeller shaft.

Wireless telegraphy is about to be established between the Island of Rhodes and Dernah, a seaport in Tripoli. The Sultan of Turkey has issued an irade which authorizes a German firm to install the system. According to the terms of the irade the service must be able to transmit at least 4,000 words in 24 hours, and the engineers representing the German firm will have to remain in charge of the new system so long as the Turkish Government shall deem necessary.

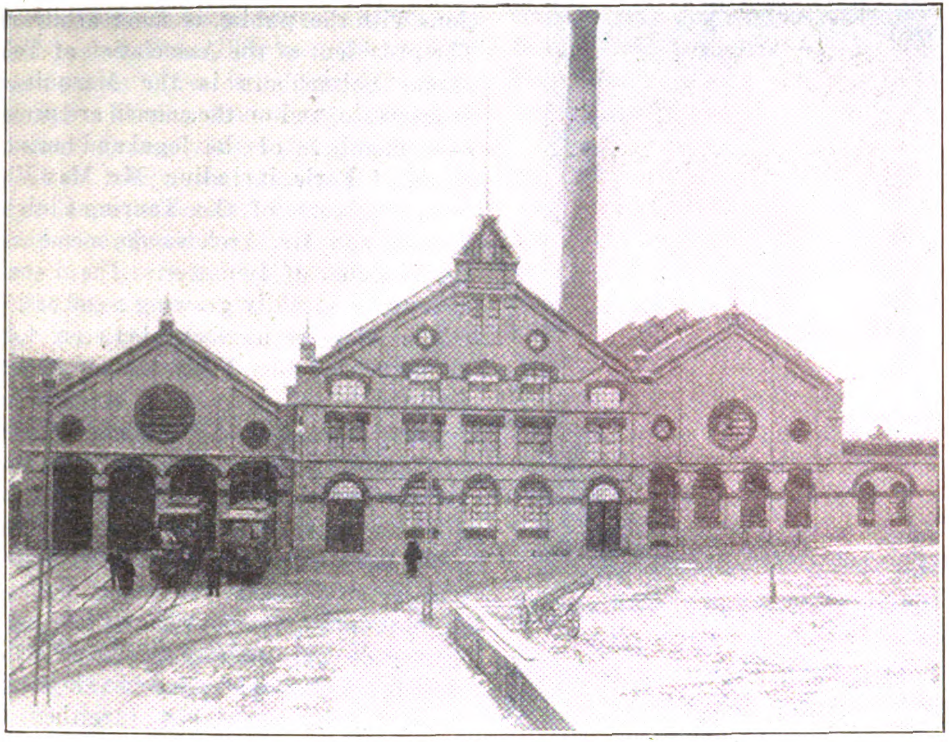
A sleet storm and a sudden fluctuation in temperature last Friday night was responsible for considerable damage to telegraph and telephone wires in this neighborhood and up New York State. West of Rochester most of the telephone wires were down and the telegraph service to Buffalo was seriously crippled.

Reports from England state that each battleship of the British Atlantic fleet will shorly be equipped with a wireless telegraphy outfit.

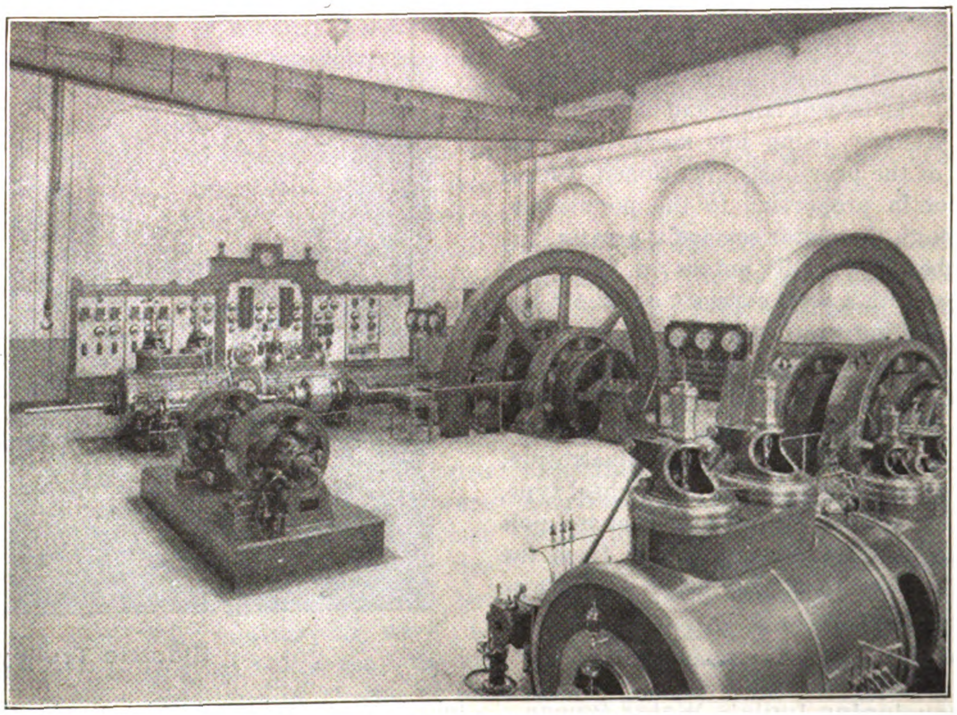
GERMAN LIGHT AND POWER STATIONS SUPPLYING CURRENT FOR ELECTRIC RAILWAYS.

BY FRANK C. PERKINS.

A great many electric lighting stations in Germany and other countries of Europe and the United States find it a profitable business to supply electric current to street railways as well as operating the electric lighting and power distribution service, as the railway work provides a heavy load in the daytime for the electrical plant while the lighting service is at a minimum during this time. The city of Dresden has a lighting plant which supplies such service, and this is also true of the Electricitatswerke der Stadt Gorlitz and the Electricitatswerke Tilsit. The illustrations show this latter station which supplies current to the Strassenbahn Tilsit. The Gorlitz station is equipped with three 200 hp. steam engines and two 400 hp. compound engines of the horizontal type, constructed by the Actien Gesellschaft Gorlitzer Maschinenbau Anstalt und Eisengeisserei in Gorlitz. These engines are operated at a steam pressure of 10 atmospheres and a speed of 125 r.p.m., being directly connected to direct current and alternating current generators constructed by Siemens & Halske. The city of Gorlitz has a population of over 80,000 with an electric lighting service including about 12,000 fifty watt incandescent lamps and 400 ten ampere arc lamps. The current is measured by 372 meters for the above service and the motor distribution includes small machines up to 123 hp. total output. The current for lighting is of the single-phase alternating system with a frequency of 50 periods per second. The distribution pressure is 2,000 volts with a secondary pressure of 110 volts. For the street railway work the generators supply a continuous current of 550 volts pressure operating in connection with a storage battery regulating installation, including 266 cells of accumulators having a capacity of 244 kw.



Power Station at Tilsit.



Generator Room of Tilsit Plant.

The accompanying illustration of the Tilsit power house shows the installation of two direct current units, each consisting of a horizontal tandem compound engine directly coupled to two multipolar generators, a heavy flywheel being mounted between them for aiding in speed regulation. These machines have a capacity of 500 kw. and are utilized in connection with a three-wire system for lighting purposes of 220 volts pressure and a 550 volts service for street railway work. The booster set, noted in the foreground of the illustration, is utilized in connection with a storage battery plant with a normal capacity of 150 kw. used as a reserve. The city of Tilsit has a population of 34,538, and the incandescent lighting service includes 3,471 fifty watt incandescent lamps and 98 arc lamps, this number being not more than half that of the previously mentioned central station in proportion to the population, although the motor service is greater, the number of small motors in use being larger with a total capacity of 22,435 hp. This station was installed with electrical equipment by the Elektricitats Actien Gesellschaft, formerly W. Lahmeyer & Co., of Frankfort-on-the-Main, Germany. The cars, as shown in the illustration, are of the single truck, four wheel type, the under running trolley wheel and pole being utilized, thus differing from the contact bow so largely used on German street railways.

Electric Trolley Cars on Tilsit Railway.

Developing India's Water Power.

An association of British capitalists has been formed and active steps are being taken toward developing the enormous water power running to waste in India and especially in the Punjab. One of the first objects contemplated is to bring to Lahore and Amritsar, both very busy and increasingly important centers of commercial activity, the immense boon of a cheap and ample supply of permanent electrical power.

ANOTHER METROPOLIS DISSATISFIED WITH ITS TELEPHONE SERVICE.*

In May last the dissatisfaction of the Paris public with regard to the inefficient telephone service furnished by the French Administration of Posts and Telegraphs took definite form in the organization of an Association of Telephone Subscribers, constituted for the purpose of bringing sufficient pressure on the Administration to improve the service. The French Telegraph Administration acquired the telephone system of Paris in 1889, and complaint is made that not only is the service very bad, but that the general practice of the Administration with regard to rules and regulations, rates and other matters of business relations with the public, is most arbitrary. The president of the Association of Telephone Subscribers is the Marquis de Montebello, and on the council are prominent members of the legal and business world of Paris, including Mr. Max Vincent, president of the Touring Club de France, and Mr. Archdeacon, member of the Chamber of Deputies. The association has a steadily growing membership, which already numbers between 4,000 and 5,000 of the Paris telephone subscribers.

Since July a monthly bulletin has been published by the association containing articles and reports on the various aspects of the telephone question in France. With a view to acquiring thorough information on the technical side of the telephone service, the council of the association recently retained Mr. Herbert L. Webb, of London, as consulting engineer. Mr. Webb has furnished the association with a report on the general conditions of a modern telephone system and with a further report on the principal causes of the defective service in Paris. Mr. Webb's first report contains a well-written popular description of the central battery system as at present employed in the most modern exchanges in Great Britain. The report even includes a description of the methods for junction working, the French expression "auxiliary" line being used instead of what is called "junction" line in England and "trunk" line in America, in order to facilitate the work of the translator. As Mr. Webb has not been allowed to visit the exchanges, his second report is based on general knowledge of the Paris telephone service acquired from public descriptions and from observations made on visits to Paris during the past few years. He divides telephone exchange working into three periods. During the first period, from 1880 to 1890 or 1892, the methods in use were largely experimental. During the second period of another five or six years, the development of telephonic apparatus was, he says, more scientific, while during the last period effective methods and apparatus have been perfected and standardized.

---

*From the "Electrician," London.

The Paris system, in Mr. Webb's opinion, has largely remained in the first period, having only adopted some improvements belonging to the second period mentioned, and being "entirely innocent" of the apparatus and methods of the third period dating from 1897. While these older methods may still be suitable for small exchanges, they should not be applied to larger systems, and, moreover, owing to the defective working of antiquated apparatus, Mr. Webb continues, the nerves of the operators are so taxed that it is unreasonable to expect a high standard of efficiency and discipline from these ladies.

Mr. Webb next criticises the peculiar practice of the French Telephone Department in compelling each subscriber to supply his own telephone set, with the result that there are various types in existence, some having radical technical defects when considered in relation to other apparatus in the system. The variety of instruments also makes it impossible to train a force of inspectors to familiarity with the peculiarities of all the numerous types. A further evil is the extensive use of primary batteries instead of magnetos or a central battery for signaling, a method which, Mr. Webb says, belongs to the first period of telephony already mentioned. The necessity of keeping these cells in order must constitute a serious cause of defective service and also be a source of great expense.

The cure suggested is the reconstruction of the whole system on modern lines, which would occupy two or three years, according to Mr. Webb's computation, during which period a gradual improvement would occur. Mr. Webb does not give an actual estimate of the cost of this conversion, but is of opinion that it would be "far less than the cost of a single battleship, and even less than the cost of an armored cruiser, and well worth the price."

In Paris the total number of telephones is about 45,000, and there is a yearly increase of about 3,600 subscribers. In New York, there is a telephone service serving over 150,000 telephones and increasing at the rate of 30,000 per year. The flat rate of charging in Paris should be abolished, says Mr. Webb, and with a scientifically arranged message rate tariff he thinks it would be possible to reduce the minimum charge to £6 or even £5 per annum.

The Association and the Telephone Administration are still in correspondence with regard to the proposed inspection of the Paris exchanges by Mr. Webb, but we understand that up to the present permission to view the exchanges has been withheld, although the President of the Association has made a formal application to the Administration that Mr. Webb should be allowed to make an official inspection with a view to reporting on their condition and on the apparatus and methods employed.

WIRELESS TELEGRAPHY IN MILITARY FIELD OPERATIONS.

BY A. FREDERICK COLLINS.

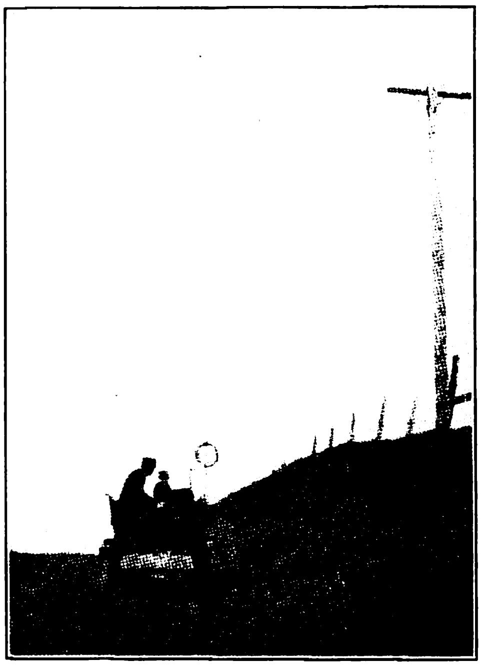
Wireless telegraphy in the Navy is infinitely easier of solution than in the Army, but its importance in the strategic operation of both these branches of the War Department is, with all its imperfections, undeniably great.

The method of sending messages by the system first introduced by Marconi had its initial trial in military manœuvres during the Boer war, when the British Government sent several equipments to South Africa. The results were not over successful, for the apparatus was of a type not readily portable but was intended instead to be permanently installed between certain given points. This was found to be impracticable as the officers could only make use of the equipment at the front; then came the difficulty of transporting 80 or 100-foot masts as well as erecting them; then kites were tried with indifferent success, for they were not adapted to the climatic conditions met with in that country. These untoward state of things, together with the fact that the instruments were as yet of the original bulky type, the art yet young and those in charge of the instruments fresh, nothing more nor less than failure could have been expected.

These unsuccessful results, due both to the system and the men who operated it, spurred Marconi on to greater effort and by the time the war was over he had evolved a wireless telegraph automobile, so arranged that the car contained all the devices for the generation of the initial energy, its transportation and its radiation, together with the receiving and translation appliances, the lofty wire being supplanted by a cylindrical aerial wire that could be folded back on the top of the vehicle.

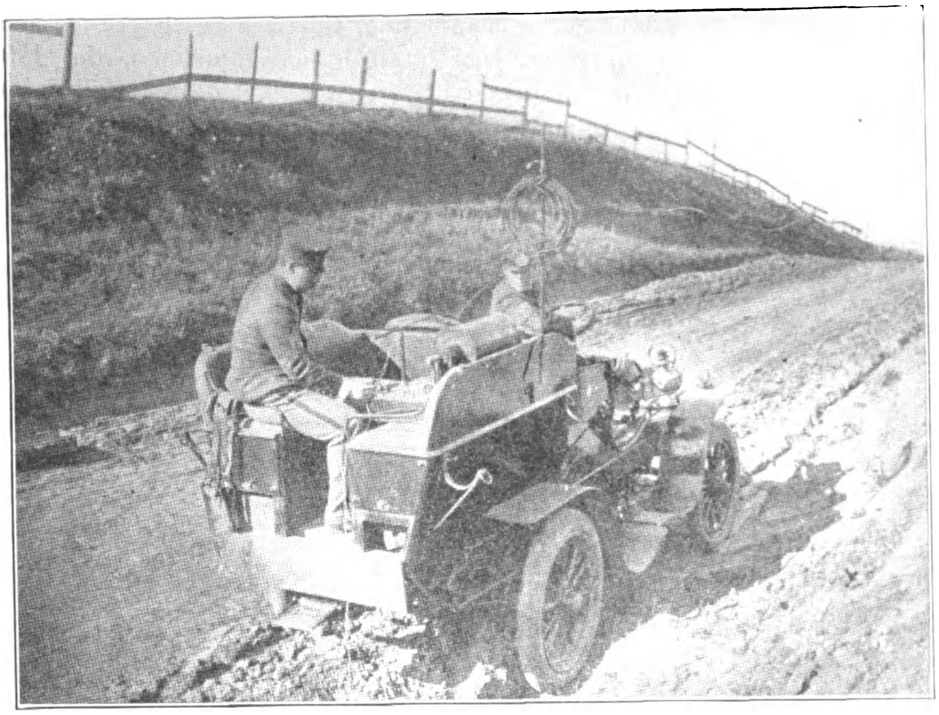
These were the first feeble but, withal, noble steps in the art of designing a portable yet serviceable apparatus for the transmission and reception of wireless telegraph messages that showed the maximum results with a minimum of knowledge on the part of those who had charge of it.

Later the development of the simple microphone detector made it possible to eliminate all the delicate mechanism inherent in the type employing a coherer and Morse register, and the Allgemine Electricitats Gesellschaft, then the owners of the Slaby-Arco system, designed a portable equipment that was subjected to exceedingly severe tests during the manœuvres of the German Army and came out with flying colors.



Temporary Field Wireless Transmitting Station.

In these tests the sending and receiving apparatus were mounted on separate horse-drawn gun carriages, the portable transmitter having a vapor engine and electric generator and the receiver having a microphone detector and head telephone. Kites of the Eddy and Blue-Hill box types and hydrogen balloons were employed, so that in a very light wind or half a gale a suitable kite could be flown or, if there is no wind at all, the aerial wire could be elevated by means of the gas-bag.



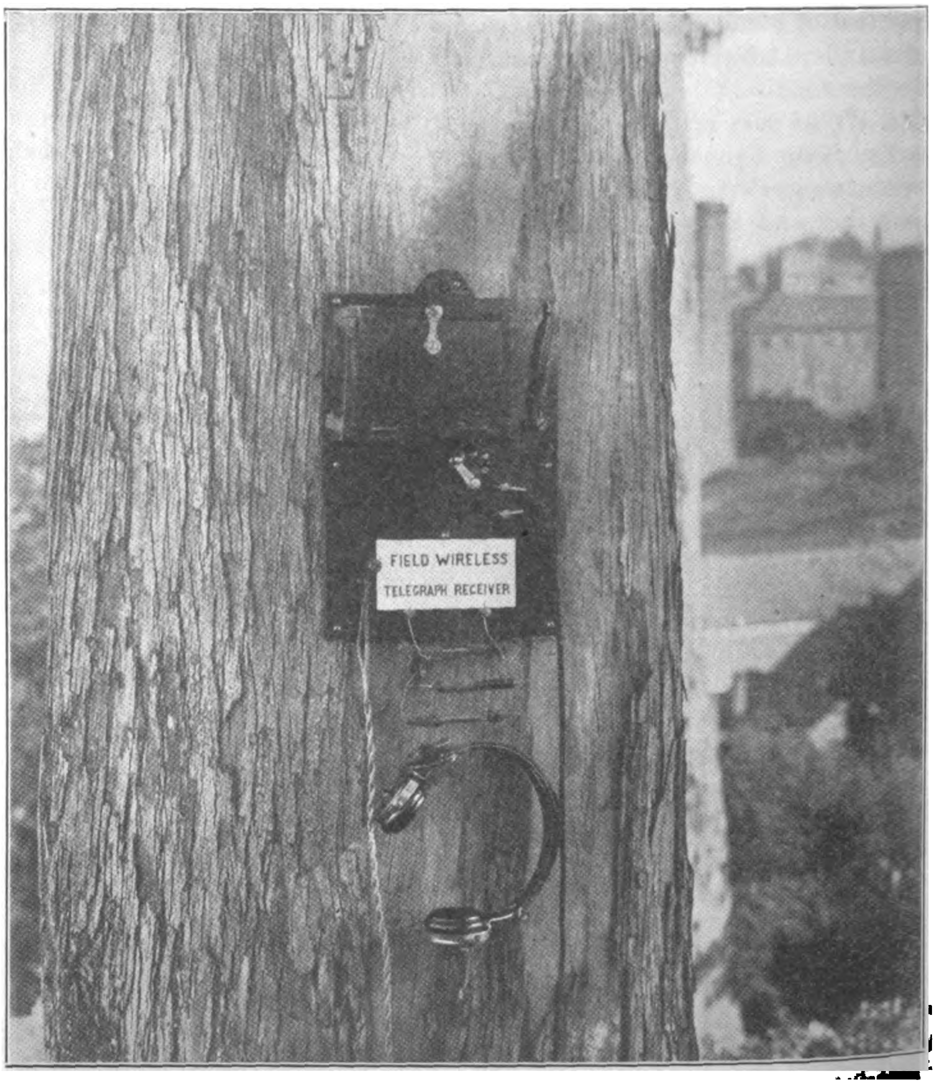
Temporary Field Wireless Telegraph Auto Car.

A modified form of this equipment has combined certain features of the Braun system as well as those of the Slaby-Arco, but its intent, its purpose and its appearance remains practically unchanged. It is noteworthy that a large number of these sets have been supplied by the Russian Government.

Recent experiments by George O. Squire, Ph. D., Major Signal Corps, U. S. A., have indicated a decided advance in portable apparatus for military field operations as well as the methods for utilizing the same. While kites and balloons are far ahead of the primeval attempts to use poles in war manœuvring, yet the former are not without their disadvantages.

In many places it is not, of course, possible to eliminate them, but there are instances where simpler means may be employed without the difficulties of manipulation of these aerial devices which may readily serve to disclose to the enemy the positions of the signal stations. By reducing the complexity of the wireless apparatus to the finality of simplicity and removing those portions of the installation, which include kites, balloons, earth plates, etc., the entire outfit is made compact enough so that it may be conveniently carried on a motor car, as shown in the illustration.

The tests were carried out at Fort Mason, Cal., an automobile having been purchased for the Signal Corps of the Army for telegraphic purposes, and this was fitted temporarily with the wireless apparatus. The initial electromotive force was obtained from two portable storage batteries of 10 volts each and these were used to excite a large induction coil made by Apps of London.



Wireless Telegraph Field Receiver at Fort Mason, Cal.

With the preliminary details thus arranged a tour was made through Santa Clara and Alameda Counties, Cal., when temporary installations were operated at various points along the route. Two different methods were employed in obtaining aerials and earths, both of which are due to Major Squire. One of these consisted of grounding the antenna to the root of a tree by driving a nail into its base, as previously described, the tree serving admirably instead of the aerial wire; in the other the aerial wire was connected to the cross-arm of a telegraph pole while the opposite terminal was earthed in the usual manner.

After a little practice, to quote the Major, two men, a sergeant and a corporal of the Signal Corps, one a good lineman and the other a chauffeur of the machine, who also acted as a telegraph operator, could install a sending station in 10 to 15 minutes; a receiving station was even less trouble to install since there was nothing to transport except what could be carried in the hands.

The best field system of wireless telegraphy for the Army, according to Major Squire, will result only after careful, tedious and exhaustive experiments and tests under the exacting conditions of actual war.

SOUTH AMERICAN TRADE—EXPORTS AND DUTIES.

Every electrical manufacturer we meet these days is to all intents and purposes an exporter as well as a manufacturer, and if proper opportunities and facilities were afforded him it is possible that the foreign shipping branch of his business might be largely developed, not alone to his personal benefit but to the advantage of his commercial community as a whole. The export problem, and it is a thorny subject to many, is one that is hardly ever out of mind. It takes new and sometimes fantastic shapes, and to carry it to a successful issue requires something more than the organization the smallest American manufacturer has at his disposal under present commercial conditions. To say, as is sometimes said, that the export trade in manufactured goods in this country has reached its limit is absolutely childish. It might with just as much reason be argued that a small dealer in opening a store should be content with the first or second week's business and do nothing to increase it.

The ebb and flow of the exports of our manufactured goods are due to causes which, in many cases, are within the control of our manufacturers, and that our foreign shipments, particularly to the countries lying to the south of us, are stationary at times is evidence that we are resting too much on our laurels, existing on victories already won by those who have gone before us, rather than framing our organization and winning fresh ones. To come straight to the point, the men properly qualified to handle our foreign trade are too small in number to adequately carry it on when we consider the enormous competition that has arisen on the part of other manufacturing countries.

Any scheme for the expansion of foreign trade requires a satisfactory arrangement for selling goods. The American electrical manufacturer with an eye for fresh markets should ascertain the duties on his goods when imported into the desired markets. Having satisfied himself that the duties are not prohibitive, and that the products are likely to find sale, he should then find a reliable agent, one in whom perfect confidence can be placed. Orders must be executed based strictly on the samples shown, as it is no use to think that, because the customer is far away, anything will do. The very fact of the distance renders it all the more necessary to exercise even greater care that in the case of home markets when the goods can be rejected and returned in the event that they are found to be unsatisfactory.

MEXICO.

Of course our nearest, and therefore the market to which we have paid the most attention, is that of Mexico. The general effort made on the part of American exporters is to find a man on the spot who can satisfactorily handle goods. As a rule this is not easy to accomplish, and the safest and most advantageous plan from all points of view is to send a representative to the field. Let him go over the ground personally and interest those whom he may find that he thinks would likely make good, permanent representatives; let him be a man thoroughly conversant with the mechanism, technique and purpose of the article or articles which he is seeking to introduce, so that he may be able to present the advantages in the most favorable light. Mexicans, and in fact all South American people, are extremely cautious about taking hold of new ideas, and in this as well as in other countries it is best that all correspondence should be carried on in Spanish. Terms of credit must be decided upon before he leaves the home office, and in this connection it would be well to always make the limit as long as possible, as all European manufacturers are willing to extend long terms, and to secure trade it is necessary in this, as in every other particular, to meet them as nearly as possible upon an equal footing. By this we do not mean that credits should be given indiscriminately.

If it is a very small order, it would be better to try to induce the customer to send cash with the order, as this would save the expense of obtaining a credit rating; if a large bill is sold, ascertain by every means at the disposal of the agent whether or not the customer is deserving of the time to be extended. R. G. Dun & Co. have branch offices in several Mexican cities—Guadalajara, Vera Cruz, Correon and Monterey—and they are always ready to furnish reports on the financial standing of companies, firms and individuals. The usual term of credit extended by European houses is six months, and this is sometimes extended to nine and even twelve months.

In Monterey American manufacturers have a very good control of the market in railway equipment of all kinds—electric street cars, engines, boilers, mining machinery automobiles, etc. This is also true of Tuxpan, and in a measure of Vera Cruz.

During the fiscal year ending June 30, 1904, for which the statistics have not yet been made public, it is found that the export of electrical appliances, including telegraph and telephone instruments, to Mexico reached a total value of $409,921, while those of electrical machinery reached a value of $564,660. The duties prevailing on all importations into Mexico are as follows:

Posts and cross pieces for telegraphs and telephones, free; wire, of copper, brass, bronze or white metal, covered with any material, 5 centavos per kilo, gross weight; bare wire, of copper, brass, bronze or white metal, not exceeding 2 mm. in diameter, 8 centavos per kilo, gross weight; the same, exceeding 2 mm. in diameter, 5 centavos per kilo, gross weight; cables, of copper, brass, bronze or white metal, covered with any material, but without a metallic sheath, and uncovered cables of the same metals, of all diameters, 5 centavos per kilo, gross weight; insulated cables with metallic sheath, free; by sheathed cables are understood electrical conductors which have for their better conservation, in addition to the insulated coverings, one or more metallic coverings over the inner or outer portion of the insulating substance, as well as the conductors, which, in addition to the nucleus of copper, have an interior or exterior covering of iron wire; cables of iron or steel wire, of any diameter, free; insulators for telegraphs and telephones, free; storage and other electric batteries, free; bulbs for incandescent electric lighting, 15 centavos per kilo, gross weight; this number comprises electric light bulbs, i. e., small lamps, such as Swan's, Maxim's, Edison's and the like, consisting of a closed glass bulb furnished with a carbonized filament, producing the light; this condition extends to commutators and sockets forming part of the bulbs, but not to candelabra and chandeliers to which the bulbs are adapted, nor to their globes, reflectors or shades, which must be dutiable according to the component material of chief value or kind, as the case may be; electric arc lamps, 5 centavos per kilo, gross weight; this section refers to lamps for electric arc lights, incandescent lights in the open air, or any other than that of lamp chimneys; the glass globes for protecting the lamps in question, or for softening the brilliancy of the light, are not included in this section, and therefore pay duties as worked glass, according to classification. By "gross weight" is meant the weight of the goods with all of their packages, both interior and exterior, without deducting the cross-framing, straw, shavings, hoops, etc., used for packing: when a package contains different goods dutiable on gross weight, the customs shall establish the tare in proportion to the legal weight attributed to each kind of goods: this "legal weight" is that of the goods with their interior packings; goods dutiable on their gross weight imported without any kind of package, or imported in packages subject to duty, shall pay duty on the total weight of the goods.

CENTRAL AMERICA.

COSTA RICA.

In the markets of Costa Rica the United States is quite an important factor, although we might control a larger share of the market if we cared to extend longer credits. European manufacturers doing business in that country extend credits of four, six, and in some cases, nine months, where we are asking for settlement within thirty days.

The imports from the United States for the past fiscal year included $83,254 of electrical appliances, $4,498 of scientific instruments and $3,172 of electrical machinery.

Duties—Articles for lighting, of metal, 22 centavos per kilo: wire cables, 2 centavos per kilo; glass articles, white or colored, for lighting purposes, 11 centavos per kilo: street railways and their accessories, free.

GUATEMALA.

There is very little soliciting or drumming for trade done in Guatemala, as the merchants and manufacturers order through commission or shipping merchants located at the principal ports abroad. The longest credits are given by Germany and the shortest by the United States. There are no mercantile agencies in the country and inquiries as to financial standings are conducted through the banks.

No exports of electrical machinery were reported from the United States during the past fiscal year, but the returns for electrical apparatus are given as $11,361, and of scientific apparatus, $2,884.

Duties—Electrical machinery and batteries, not charged, destined for public service, free; electrical apparatus, except chemicals employed in the operation of same, 2 centavos per kilo, gross weight; globes, glass, for incandescent lamps, 2 centavos per kilo, gross weight: carbons for galvanic batteries, free: galvanic batteries and their extra parts, free: articles for electric lighting from the United States, free.

NICARAGUA.

The trade of Nicaragua is largely divided between the United States and England, that with the United States being conducted through the mails and by salesmen. The terms of credit granted by the United States are from 60 to 90 days and by England from six to nine months. There are no regular mercantile agencies from whom reports can be obtained, but Consuls and any of the old established houses will give the desired information.

The imports for the past fiscal year included $3,722 worth of electrical appliances, $3,581 of scientific apparatus, and $543 of electrical machinery.

Duties—Telegraph and telephone poles, free; wire, covered or not with any other materials, of copper, 25 centavos per kilo; wire, copper, covered with silk or wool, 50 centavos per kilo; wire, copper or brass, of all kinds, exceeding 3 mm. in diameter, free; insulated copper wire for electric lights, free; electric batteries for industrial purposes, free; electric machines for medical practitioners, 50 centavos per kilo.

PANAMA.

The foreign countries doing most of the trade with Panama are the United States, England, France, Germany and Italy, there is also a small trade with other European countries and with Japan. Here the conditions are somewhat reversed, the major part of the trade with European countries being done through salesmen, and that with the United States through the use of the mails. European datings are usually 90 days, with an occasional extension to six months. With the United States it is chiefly a cash basis that maintains.

In view of the prominence that is being given to this country on account of the construction of the canal, there will be some material growth, and it would be wise for those desirous of extending their fields in this direction to go down and look over the ground, particularly in the cities of Panama, Colon and other towns located in the zone. But there is no boom, such as has been indicated by some glowing reports that have found their way into our papers during recent months. Agricultural and mining possibilities have still to be developed, and there will be a steadily growing necessity for railways of all kinds, and a market for the supply of the necessary equipment for same.

The exports from the United States to Panama within the past fiscal year included electrical machinery to the value of $266, electrical appliances to the value of $6,556, and scientific instruments amounting to $2,982.

Duties—The general provision for unenumerated articles is 15 per cent. of their invoice value; machines, the total weight of which exceeds 1,000 kilos, free; materials for the construction of telegraph lines, free.

SALVADOR.

There seems to be very little to say about the trade relations as they exist at the present time in Salvador, but it is quite evident from the returns for the past fiscal year that there is a good and growing market for the sale of electrical supplies, evidenced by the fact that we sold there electrical appliances and apparatus to a value of $9,925, scientific apparatus to the value of $3,117, and while there were no shipments of electrical machinery it does look as though the prospects for the future in this country are good.

Duties—Scientific instruments free, when not otherwise specified: articles for lighting, lamps, chandeliers, etc., of metal, glass, crystal, and porcelain, with all their accessories, holders, brackets, arcs, burners, etc., of ordinary metal, 25 centavos per kilo: graphite or plumbago in powder, 10 centavos per kilo: machines, electrical, small, 30 centavos per kilo: articles, apparatus, tools, and materials not specified, for railroads, telegraphs, electric light, 1 centavo per kilo.

SOUTH AMERICA.

ARGENTINE.

Electrical enterprise has received great impetus in this country during the past few years, and there is still a large and growing field open to it. Rapid strides have been made in developing the resources of the country. Notwithstanding its area of 1,319,247 square miles, it has only a white population of about 5,000,000.

Through its diplomats at Washington Argentine has asked for what it describes as reasonable reciprocal tariff concessions, claiming that if an agreement can be reached on this matter the present trade between the two countries can be trebled in volume. A strong appeal has been made and the assistance of the United States has been asked for the purpose of developing American trade in this way. This request follows closely upon the installation of improved facilities for transporting commercial commodities through the country and the introduction of fast mail and passenger steamers between New York and points on the River La Plata.

Argentine stands third in the list of South American countries in its receipts of electrical machinery from the United States during the fiscal year of 1904, with a value of $30,741; also third in its receipts of electrical appliances, with a value of $115,686, and of scientific instruments the total import value from this country was $40,660, the highest shipments made to any of the South American countries in this particular line of industry.

Duties—Accessories of all kinds, such as switches, or fusible wire, interrupters, alarm keys, buttons, commutators of all shapes and systems, with porcelain base and cover, 25 per cent. on a valuation of 55 centavos per kilo; the same, with porcelain base and metal or paper mache cover, 25 per cent. ad valorem on a valuation of 90 centavos per kilo, the same, with slate or marble base, with or without cover, 25 per cent. on a valuation of 120 centavos per kilo; the same, in the form of spare parts of bronze or copper, without their bases of porcelain, slate or marble, 25 per cent. ad valorem, 2 pesos and 50 centavos per kilo; bronze sockets and connections, 1 peso and 50 centavos, duty 25 per cent; insulators, glass, 6 centavos per kilo gross; insulators, earthenware, or porcelain, of more than three cm. in diameter, with or without hooks. 12 centavos per kilo, gross; the same up to 3 cm. in diameter; 25 centavos per kilo, gross; wire, or cables of copper, up to 5 mm. in diameter, covered with cotton, gutta-percha or other materials, excluding wire covered with lead or silk and flexible cords of all kinds, 70 centavos per kilo; the same, of more than 5 mm. in diameter, 60 centavos per kilo; the same, up to 5 mm. in diameter, covered with lead, 50 centavos per kilo; the same, of more than 5 mm. 50 centavos per kilo; the same, of whatever diameter, covered with silk, 50 centavos per kilo; the diameter of the wire is calculated on the wire itself; wire, strengthened, underground, with interior envelope of lead and iron or steel armor, 40 centavos per kilo; the same, of iron or steel, covered with cotton, gutta-percha, or other materials, 30 centavos per kilo; wire, flexible cords, with two or more conductors of copper, spiral-shaped, of any diameter, covered with cotton, wool or other materials except silk, 1 peso and 50 centavos per kilo; the same, covered with silk, 2 pesos and 50 centavos per kilo; Morse's telegraphic apparatus, 18 pesos each; sheaths or tubes of porcelain, 12 centavos per kilo; articles for lighting not mentioned, of bronze or yellow metal, whether nickeled or silvered or not, with or without glass parts, 1 peso and 50 centavos per kilo; the same, of iron or zinc, of all kinds, 25 centavos per kilo: knobs, wooden, for electric bells, 40 centavos per dozen; the same, pear-shaped, and other kinds, 80 centavos per dozen: electric bells, 50 centavos each; carbons for arc lamps, 20 centavos per gross kilo; insulating tape of any materials, 1 peso and 10 centavos per kilo; electric light meters or regulators, 12 pesos each: vulcanized fiber in plates, 50 centavos per kilo: vulcanized fiber in tubes or bars, 1 peso and 60 centavos per kilo; portable galvanometers, 8 pesos each; arc lamps or regulators and their corresponding resistances, fittings and globes, up to 60 cm. in height, except bulbs and supports, 12 pesos each; same, more than 1 meter, except bulbs and supports, 20 pesos each: incandescent lamps, 2 pesos per dozen; electrodes of copper or bronze for batteries, 40 centavos per kilo; same, of zinc, 15 centavos per kilo; electric motors for fans, complete or not, 10 pesos each; hooks of iron for insulators, 12 centavos per kilo; batteries of all kinds, 25 centavos per kilo; porous jars, charged, for batteries, 12 centavos per kilo, gross; same, not charged, 20 centavos per kilo, gross; suspensions of porcelain for incandescent lamps, with glass, 35 centavos per kilo; telephones, magnetic, finished or not, 7 pesos each; insulating tubes of Bergmann's system, with accessories, such as sockets, elbows, etc., not coppered, 30 centavos per kilo; same, coppered, 40 centavos per kilo; same, of iron, 15 centavos per kilo; jars of glass for batteries and accumulators, of any form and size, 7 centavos per kilo; same, of earthenware or varnished, 10 centavos per kilo. In each instance the word evaluation should precede figures in the foregoing, and the duty on the articles enumerated is 25 per cent. of the evaluation as given.

BOLIVIA.

Not very much can be said of the present outlook for electrical manufacturers with the exploiting of their wares in Bolivia at the present time, as there is not a single dollar's worth of exports along these lines reported from the United States during the past fiscal year. The trade, quite large in the aggregate, is almost exclusively in the hands of German manufacturers, as the demand is for cheap articles, a fact to which the Germans cater whenever they find it to exist.

Duties—The very explicit customs regulations are very rigid and provide for every detail of consular invoices, manifests, samples, etc. The evaluation is set by the customs authorities, and the percentage to be paid is calculated on this evaluation; insulators, for telegraphs and telephones, 35 centavos gross weight, free; wire conductors for electric currents, including packages, 42 centavos per kilo, free; iron, wire, for telegraphs, etc., 80 centavos per kilo, free; accessories for telegraphs and telephones, free; cable wire, free; lamps and furnishings for electric lighting, free.

BRAZIL.

Electrical firms wishing to do business with Brazil need first to study the markets and become acquainted with their wishes and peculiarities. A good commercial traveler who can speak Portuguese is worth more than a ton of circulars and catalogues, which are seldom read even when printed in Portuguese, the language of the country, and they are practically useless when they are printed in English, which is almost unknown. It is surprising to see that some of our very largest firms do not realize these facts.

The terms of credit are with the European house from 60 to 90 days, and in some instances six months, while from the United States the request is nearly always that the business shall be conducted on a cash basis. Notwithstanding the adverse conditions under which we are laboring our trade with Brazil in electrical instruments and machinery during the past year amounted to more than that of any other South American country—$125,661; in electrical appliances the values were $271,120, and in scientific instruments, $32,744.

Duties—Receptacles and vessels of earthenware, for batteries, insulators and all other articles combined or not with copper fittings for electric installations, 200 reis per kilo; wire cables, 48 per cent. ad valorem; electric machinery, 15 per cent. ad valorem.

CHILE.

The outlook for American trade with Chile and the entire southwest coast is fairly promising. It would be eminently so if some means could be devised to enable us to successfully compete with European countries in the matter of transportation facilities. The principal contributors of supplies for those markets are England, Germany, France, Italy, Spain, Peru, Australia and Canada. Business is conducted both by traveling salesmen and through commercial agencies. The terms of credit asked and granted by most manufacturing countries are 90 days after the receipt of the goods, although this is sometimes further extended if the exigencies of the case seem to demand it.

Our own exports of electrical machinery to that country during the fiscal year ending June 30, 1904, were given as $20,355; of electrical appliances at $48,805, and of scientific instruments at $20,534. This is encouraging and is an evidence that there is a market to be developed if the proper care is given to it.

Duties—wooden pushes for electric bells, 6 pesos and 50 centavos per kilo, including package, duty 25 per cent.; cross arms for telegraph poles, 30 centavos per kilo, duty 25 per cent.; telephonic and telegraphic apparatus, insulators, iron or steel posts and other appliances for telegraphs and telephones, except wooden brackets for posts, free; machines, apparatus, and special accessories for illuminating by electricity, except lamps of all kinds, but including bulbs and candles, free; iron or steel plant for railroads, whether steam, animal or electric traction, free, with the exception of such material as may be dutiable at 15 per cent. ad valorem.

COLOMBIA.

Colombia is commercially burdened in various ways. Not only is it dependent largely upon its export trade for the conditions commercially in all lines within its boundaries, but it is also burdened with a standing army and a very expensive consular service, both far beyond its means. Our exports to Colombia during 1904 only amounted to $4,601 in electrical machinery, $22,791 in electrical instruments and appliances, and $7,412 in scientific apparatus.

Duties—Materials for public railways of all kinds and telegraph wire for public use, free; same, for private use, 2½ centavos per kilo; motors of all kinds and of any power, 2½ centavos per kilo; to the foregoing are to be added surtax charges, which vary from time to time, according to discretion of the Government.

ECUADOR.

Nearly all the exporting manufacturing countries find markets in Ecuador, and there are constantly increasing opportunities for new trade. The terms of credit extended by the United States are from 30 to 60 days from the date of invoice, while from European countries they are six and more often nine months from date of invoice.

Our exports of electrical instruments in 1904 were placed at $15,375, of scientific apparatus at $2,920, and of electrical machinery at only $154.

Duties—Railway plant and accessories of every description, free; conduits, 2 centavos per kilo; telephonic and telegraphic apparatus, 25 centavos per kilo.

PARAGUAY.

Not much business can be expected between the United States and Paraguay until such time as we have better transportation and banking facilities. At the present time all money has to be sent through some London bank. Large quantities of American goods are being sold in the markets of that country, but we get no credit for them as they are sold through German, French and English agencies, and are considered by the inhabitants to be of the manufacture of the countries through whose agencies they are received.

Duties—general articles, unenumerated, 35 per cent. ad valorem; telegraph wire, scientific instruments and railroad equipment, free.

PERU.

There is a large and constantly increasing trade to be secured in Peru, but to do so American manufacturers must conform to the practice of European countries, i.e., send competent traveling men, well versed in the Spanish language, who understand the customs of the country and the local methods of business. Great Britain is the largest shipper, and the United States, while millions of dollars behind her, is fast becoming a strong factor in this market.

There is a very bright future for the electrical manufacturer in that country if the business is properly handled. During last year Peru furnished the second largest South American markets in electrical appliances and instruments, amounting to $140,005; and the same is true with regard to our exports of electrical machinery, the total value of which amounted to $90,802.

Duties—The duties are 40 per cent. on an appraised evaluation as follows: Accessories generally, such as switches, contact makers, interrupters or alarm-keys, buttons, commutators of any shape or system, with porcelain base and cover, 60 centavos per kilo; insulators of glass, 7 centavos per kilo, gross weight; same, of earthenware or porcelain, exceeding 3 cm. in dimeter, with or without hooks, 15 centavos per kilo, gross weight; same, not exceeding 3 cm. in diameter, 30 centavos per kilo, gross weight; wire or cables of copper, up to 5 mm. diameter, covered with cotton, gutta-percha or other material, excepting those enveloped in lead or silk and flexible cords of all kinds, 85 centavos per kilo; same, exceeding 5 mm. in diameter, 7 centavos per kilo; same, up to 5 mm. in diameter, covered with lead, 60 centavos per kilo; conducting cables for electricity, with lead cover and iron and steel frame, 5 centavos per kilo; same, of iron or steel, covered with cotton, gutta-percha, or other materials, 4 centavos per kilo; flexible cords, with two or more conducting wires of copper, spiral shaped, of any diameter, covered with cotton, wool or other material, 2 sols and 50 centavos per kilo; same, covered with silk, 3 sols and 75 centavos per kilo; ordinary knobs of wood for electric bells, 50 centavos per dozen; same, pear-shaped and other kinds, 1 sol per dozen; electric bells, 1 sol each; carbons for arc lamps, 18 centavos per kilo, gross weight; insulating tape of any material, 1 sol and 40 centavos per kilo; electric light meters or regulators, 15 sols each; arc lamps or regulators, with corresponding resistance arrangements, fittings and bulbs, of a total length under 60 cm. each, 15 sols each; same, from 60 cm. to 1 m. in length, 22 sols and 50 centavos each; same, exceeding 1 m. in length, 30 sols each; incandescent lamps, 3 sols and 50 centavos per dozen; hooks of iron for insulators, 15 centavos per kilo; porous jars, charged, for batteries, 15 centavos per kilo, gross weight; hangers of porcelain for small incandescent lamps and for lanterns, with glass, 45 centavos per kilo; same with claws, sockets and connections of bronze, 50 centavos per kilo; telephones, magnet, 9 sols each; insulating pipes with their adjuncts, such as elbows, sockets, and other parts, not being covered with copper, 35 centavos per kilo; same, covered with copper, 50 centavos per kilo.

VENEZUELA.

In Venezuela again we are at the disadvantage of short credits, the usual request being for cash with the order, or remittance by return mail, whereas when goods are imported from European houses the credits are from three to six months, and this is in the favor of the merchants in that country, who, as a rule, have not a sufficient capital invested to enable them to pay cash on delivery.

Our exports direct to Venezuela during the past year reached a value of $58,074 for electrical appliances, $11,567 for scientific apparatus, and $943 for electrical machinery, of which large quantities were shipped through European countries.

Duties—Accessories and complementary parts for telephone lines, 30 centavos per kilo; accessories and materials for railroads, free; telephonic apparatus, 30 centavos per kilo; cables, 30 centavos per kilo; carbons, coal and carbons for electric lighting, and telegraph machinery and apparatus, free.

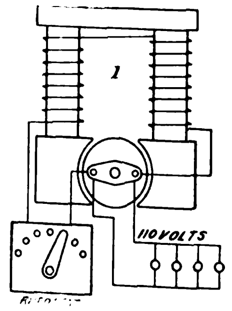
ELECTRICITY LEAFLETS.

BY NEWTON HARRISON, E. E.

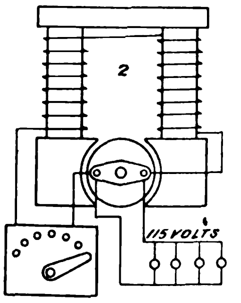
ELECTRIC LIGHTING.

Incandescent Lighting.—The lighting of incandescent lamps is one of the most important departments of electric lighting in large cities. It is done by means of alternating as well as direct current. If a direct current system of lighting, the character of the dynamo employed will be either shunt or compound wound. When conducted on an enormous scale, as in the case of stations which supply an entire city with electricity for light and power, low tension direct current lighting is associated with high tension two or three-phase alternating. This last, as will be shown, is employed to further the economy of transmission to points more or less distant from the original generating plant. In other words, the use of high tension alternating currents, in conjunction with low tension direct, is for the purpose of instituting a series of secondary or distributing stations, substations as they are called, which are utilized as new centers of electrical supply.

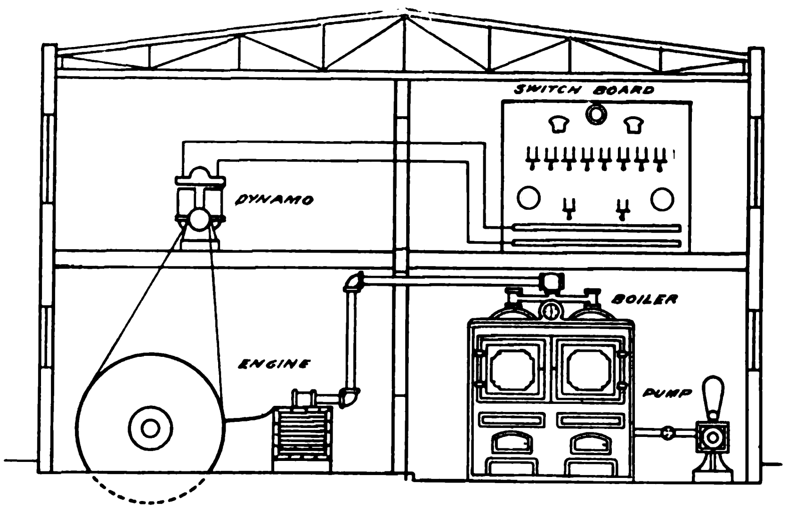
Regulation of Shunt and Compound Wound Dynamos.—The machines eminently suited to the service of supplying an incandescent system with its energy are the shunt and compound wound dynamos. They are installed under circumstances which require consideration. For instance, it is customary to use compound wound generators for private installations. In this case, the dynamo is practically automatic in its action, which means, that between no load and full load, the minimum and maximum of lights, it will preserve a comparatively uniform pressure. On the other hand, if a shunt dynamo is installed, every important change in the number of lights will necessitate an adjustment of the resistance inserted in the field or shunt winding. When the various consumers of the current turn the current on or off, the dynamo, sensitive to such changes, will vary its terminal or brush pressure. A weaker or heavier current coming from the armature will raise or lower the potential difference at the brushes. Constant watching is required to preserve a uniform potential by increasing or diminishing the current in the shunt winding. When the current in the winding of the fields is increased by cutting down the resistance in the rheostat, the amperes or ampere turns of said winding increases. The lines of force of the field increase, and the EMF. generated by the dynamo. The reverse happens when the resistance in the field winding is increased. The smaller a shunt wound generator the more constant must the attention be to this method of regulation. If the generator is very large, such, in fact, as have been employed in the Edison station in New York City, where the station load reaches over 200,000 amperes, then the use of shunt wound generators with such regulation as described is good practice. In this case, station assistants are always at the rheostats to meet the rising or falling tide of electricity with a resistance adjusted to preserve the constant potential character of the system. Contrary to expectations this is a very reliable method of regulation and meets every requirement, many, perhaps, which might be overstepped by dependence upon a purely automatic system.



1—Some resistance in shunt coils, gives a pressure of 110 volts.



2—No resistance in shunt coils, gives a pressure of 115 volts.

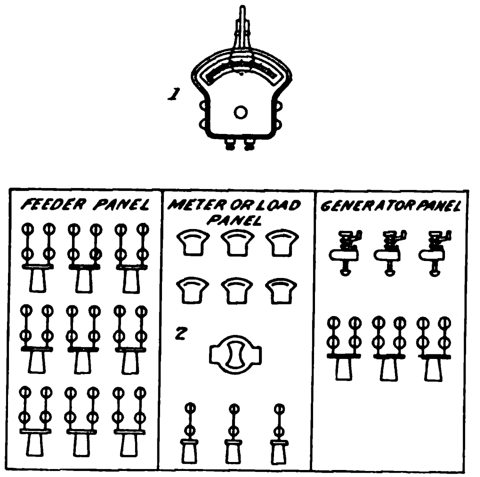


ESSENTIAL PARTS OF AN ELECTRIC PLANT.

A Private Electric Light Plant.—The essentials of a private electric light plant might be classed under the following heads:

Mechanical.	Electrical.	
Boiler.	Dynamos.	Circuit Breakers.
Pumps.	Switchboard	Lightning Arresters.
Engine.	Wiring.	Ground Detectors.
Steam Fittings.		Main Switches.

The dynamo, switchboard and wiring are necessarily parts of the same system, that is to say, if the building has been wired with the two or three-wire system the switchboard would be equipped, and the dynamo or dynamos connected up in accordance with this plan. The dynamo, whether shunt or compound wound, would be supplied with a rheostat and a voltmeter and ammeter.

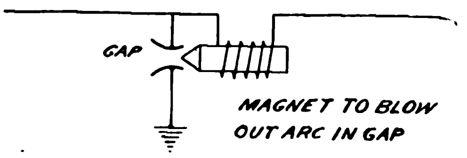


1—Station type of Weston meter—illuminated dial. 2—Departments of a switchboard.

The Switchboard.—The switchboard can be best understood with reference to a classification which takes into consideration the various functions it is to perform as follows: Parts of a switchboard:

- Generating Department.
- Distributing Department.
- Metering Department.

By this is meant that there are three functions performed by a switchboard—to receive the main wires from the generator or generators, to distribute or feed this current to the various circuits connected all over the building and to measure or meter the energy both as regards its volts and amperes separately, as well as its watts in total. It is now possible to purchase small switchboards which are



Lightning Arrester with Magnetic Blow-out.

merely parts of a complete board, called "generator, feeder and meter panels."

Lightning Arresters.—Central station as well as private plants are subjected, to a greater or less extent, to the influence of lightning or electrical storms. The electrostatic discharge must be led to the earth before it reaches the generator. To accomplish this, use is made of the principles in static and dynamic electricity which govern the movement of the charge. These ideas are embodied in a device called a lightning arrester. It is invariably supplied with either an air-gap proper or a very high resistance path leading to the earth. The lightning discharge is thus given the choice of continuing along the circuit where it will meet with retarding or impeding influences, or of reaching across the gap provided and reaching the earth at once. Kicking coils are employed between the line and the generator where the system extends beyond the station or private plant, to artificially augment the difficulties a static discharge will meet with in advancing on the machines. The inductive reaction or electrical kick, as it is called, proves an effective protection in conjunction with the arrester against sudden rises of potential in the system. These electrostatic surges of pressure attack the integrity of the line and plant by tending to break down the insulation, and thus cause grounds or short circuits.

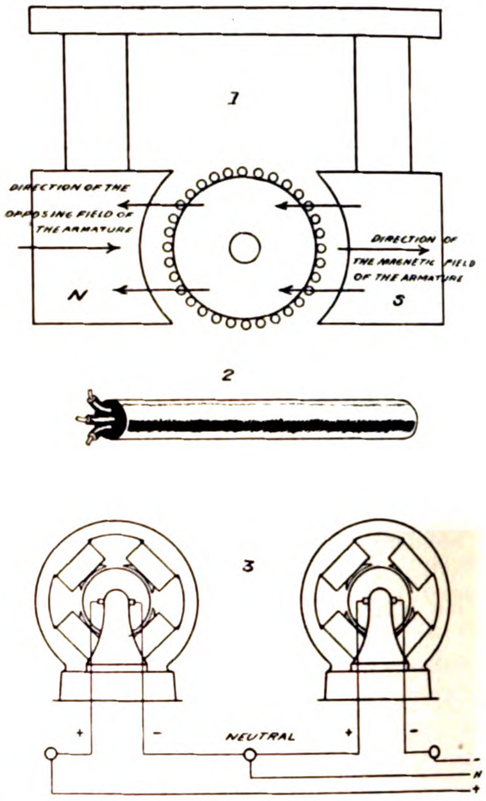
The Incandescent Lamp.—Not the least in importance is the lamp itself, on whose virtues hang the successes which are to follow. The incandescent lamp represents the source of illumination from one standpoint. From the other, it must be regarded as the basis for the most important of all calculations in the way of economy and efficiency. There are three features to an incandescent lamp which bear upon the question of a plant's success. They are the life, candle power and efficiency of the lamp. The average life of an ordinary 16 candle power lamp is about 600 hours. The candle power is rated as 16 with the normal pressure in the circuit. The efficiency of an incandescent lamp, or its wattage per candle power, generally reaches between 3 and 4. By this is meant that a 16 cp. lamp may consume anywhere from 16 × 3 to 16 × 4 watts to produce its light. The manufacturers of incandescent lamps have learned by experience that any increase in the efficiency of lamps, any increase in the candle power and decrease in the watts consumed, is only gained at the expense of the life of the lamp.

The problem therefore becomes self-evident, when it is known that an increase in a few volts will so rapidly raise the cp. of a lamp that it falls within the category of less than 3 watts per cp. If the normal pressure is reduced the same holds true in a reverse sense. In this case the lamp takes more than 4 watts per cp. and is very inefficient.

Regulation, as it is called, that is to say, the preservation of a uniform potential in the entire system of electric lighting is necessary if any relationship is to be kept between the light produced and the power consumed in producing it. A fall of a few volts in the generator means a reduction of between 20 and 30 per cent. in the candle power of the lamps. A rise of a few volts, will send so much more current through the lamps and so increase the candle power, that the life or durability of the lamps is reduced. The increase in current with a few volts, is due to the lowering of the resistance of the carbon as its temperature rises. A hot carbon conducts much better than one that is cold, and when, as in the case of a carbon lamp filament, incandescence is reached, it becomes very sensitive to a slight increase in pressure.

Power Consumption and Lamp Life.—These two factors are closely associated in the statistics of power stations or central stations as they are called. If the lamps begin to grow dim, which they do about their 400th hour of life, either new lamps or more volts must be employed. If a higher pressure is sent over the line, the power consumption becomes very much greater. For instance, with 1,000 lamps, each taking 50 watts 50,000 watts are required when the lamps are new, when they are old if the watts per lamp rise to 64, then 64,000 watts are necessary. The difference, 14,000 watts, represents enough cost in the way of coal, that service of this kind if continued becomes more expensive than lamp renewals. If the pressure is not raised, the lamps will burn very dimly and instead of the 16 cp. and 3 watt per candle consumption, there will be about 12 cp. and a 4 watt per candle consumption. Thus, the power of the plant will be devoted to the production of only 75 per cent. of the light, which is the worst possible practice. In this case, the general dissatisfaction as in the case of office buildings may be the cause of vacancies, which will make such economy a costly experiment.

The Wiring and the Amature.—The wiring may be correct according to the Underwriters' requirements and only have a 2 per cent. loss in volts. But in addition there is the armature to be considered. The armature conductors also cause a drop in volts when the load or current increases or diminishes; and the represent an electro-magnetic influence which opposes the magnetic field they revolve in, reducing it and thus cutting down the volts. Thus, it may be said that the regulation of a shunt or compound wound dynamo depends upon the



1

1—Cutting down of the Dynamo Field by the Armature. 2—Three wires incased in conduit for subway use. 3—Two Dynamos connected up for the Three-wire System.

1—Drop in the armature conductors.

2—Reverse magnetic field in the armature conductors.

3—Drop in the wiring.

A recapitulation of the facts now clearly shows, that in incandescent lighting by direct current, by means of shunt or compound wound dynamos, the candle power produced and the efficiency of the lighting, depend upon the quality of design exhibited by the dynamo, the attention paid to drop in the wiring and the watts per candle power of the lamps.

The Two and Three Wire System.—The streets of New York are networks of copper wire incased in tubes or conduits. These wires compose a gigantic 3 wire system of conductors which is continued in every house which draws its power for lighting from this source. The two wire system is a simple extension of the idea of using 2 wires, between which are supplied by means of a variety of branches of 2 wires each all the lamps to be lighted. The 3 wire system dispenses with one wire, connecting dynamos of 110 volts pressure, between the outer and middle wires. The + pole of one dynamo is connected to an outer wire and the — pole to the middle wire. The — pole of one dynamo is connected to the other outer wire and the + pole to the middle wire. This gives two dynamos in series, with one wire emanating from the common or neutral pole called the neutral wire. The other two wires, one on each side of it, are respectively the + and — wires. They are also called the outer legs of the system.

OXYGEN AND HYDROGEN BY ELECTROLYSIS.

BY EMILE GUARINI.

As the number of the various applications of oxygen and hydrogen gas continue to increase, the greater become the efforts of inventors to produce these gases economically.

The principal application of these gases in the arts is the production of high temperatures for various purposes, such as the melting of platinum and other metals, and alloys, which have a high fusion temperature, for producing the Drumont light, for working hard and soft solders, and especially for soldering lead in sulphuric acid works, and for brazing or welding copper and other such metals in watch-making, and in the manufacture of jewelry and instruments of precision. While lately it has commenced to be used for producing the oxy-hydrogen flame for brazing aluminum, iron and for the partial annealing of armor plates.

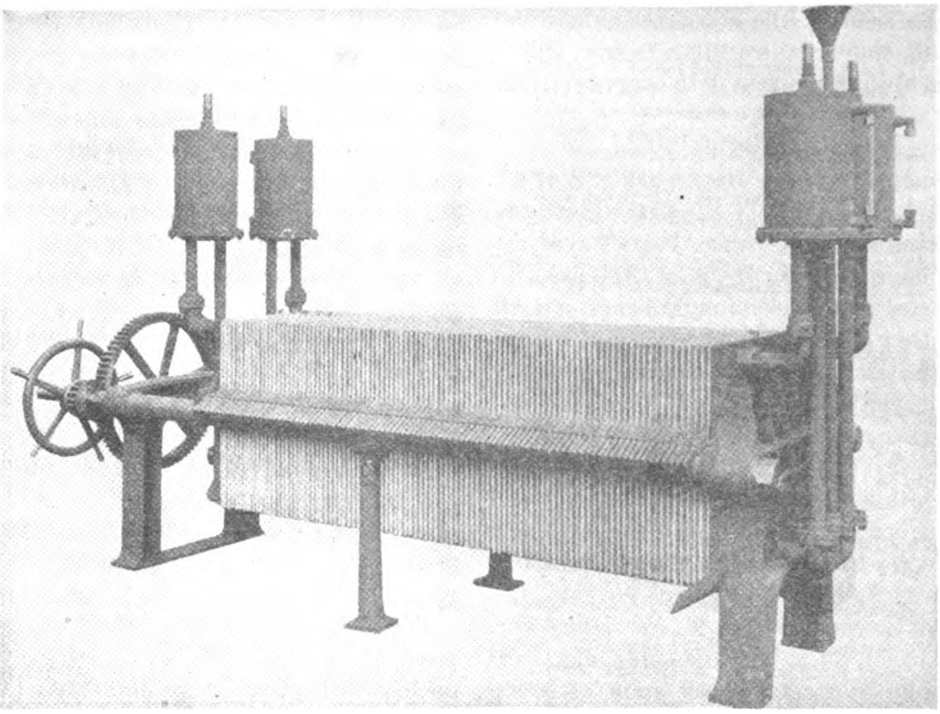
Oxygen alone finds many applications in chemical and metallurgical industries, in the manufacture and refining of steel, for laboratory and for medical purposes; while hydrogen by itself is used for inflating balloons and for incandescent gas lighting.

The oxy-hydrogen flame has an advantage over the electric arc, of being readily and easily regulated, and in not being colored, for it is possible to govern the admission of the gas in such a way as to obtain an oxidizing or reducing flame.

The powerful calorific effects of the flame permit of its being quickly used for soldering pieces of large dimensions, with hard solder. This process is very readily adaptable to the quick joining of those points which have failed to be welded by firing, without having need to submit the entire piece to a refiring, which would effect all the parts that had previously been welded, for the blow-pipe flame is able, without difficulty, to reach those parts not readily accessible.

We are able to obtain oxygen and hydrogen gas by the electrolytic method, and hydrogen produced by electrolysis costs but very little per cubic meter, or about 2 cents under the most unfavorable conditions, while its production by means of the action of sulphuric acid or zinc or on iron, would cost at a minimum 50 cents, while oxygen produced by the same method costs no more, and the electrolytic method of production will remain the cheapest until it becomes possible to economically produce oxygen from the atmosphere.

The Oerlikon electrolyzers are composed of a certain number of successive compartments, containing cast plate electrodes. The apparatus very much resembles that of a filter press. The insulation of the various plates is secured by resistant diaphragms, which at the same time keep the compartments perfectly water and gas tight. The gases are produced at the surface of the electrodes and escape through holes pierced through the plates. These holes communicate with two longitudinal pipes which convey the gases toward the separators, where the gases and the liquid are separated from each other; the electrolyte is conveyed back through a single pipe to the compartments, while the formation of the gases due to the passage of the current keeps up a continuous circulation of the electrolyte.



The Oerlikon Electrolyzer.

The cost of producing these gases by the Oerlikon apparatus is surely very low; 12 kilowatt hours is wholly sufficient to produce 1 cubic meter of oxygen and 2 cubic meters of hydrogen. Consequently, the cost of producing the gases will principally depend on the cost of the electric energy used, as the first cost of the apparatus and the interest on the investment are negligible quantities when compared with the quantity of the gases produced per annum.

The cost for current will vary according to circumstances from one-fifth of a cent per kilowatt hour, where economic hydraulic power is available, to 6 cents or more in small installations where steam power is used. Allowing an average price of 1 cent per kilowatt hour, the following cost prices are obtained:

1 cubic meter of oxygen + 2 cubic meters of hydrogen.....	12 cents
1 cubic meter of hydrogen + ½ cubic meter of oxygen.......	6 cents
1 cubic meter mixed....	4 cents

The oxygen produced by this method is at least 97 per cent. pure, the impurity consisting of hydrogen mixed with a small quantity of protoxide of carbon. The hydrogen is 99 per cent. plus 1 per cent. of oxygen. A simple device allows of both gases being obtained quite pure.

These electrolyzers decompose 134 grams of water per kilowatt hour in producing 168 liters of hydrogen and 84 liters of oxygen. The output of the apparatus when warm amounts to 8 per cent., and these electrolyzers will readily carry a temporary overload of 25 per cent.

The usual construction of these Oerlikon electrolyzers allow of the gases being produced at a constant pressure, which may attain an equivalent of 2½ meters of water.

The electrolyte consists of a solution of 10 per cent. of carbonate of potash in distilled water, and it undergoes no chemical change under the action of the current. The decomposed water is replaced by distilled water.

The simple construction of this apparatus allows of its being very quickly cleaned, and when it is operated continuously this is only necessary about every eight weeks, and no other attendance is required except to replace the water as it is decomposed.

The electrolyzer when cold requires about 2.7 volts per compartment, and when it is warmed up a current of 2.3 volts is all that is required. The maximum temperature of about 60 per cent. Centigrade, is obtained after the apparatus has been in operation eight hours.

The advantages of the Oerlikon electrolyzers may be summed up as follows: Simplicity of construction, ease of operation and low cost of maintenance. As may be seen by the accompanying illustration, they require little space, which is not always the case with other systems.

Animal Electricity.

A dispatch to the New York "World" from San Francisco, Cal., states that tests covering a period of two years have just been completed by Dr. A. J. Atkins, who believes that the brain and heart and all the other organs of the physical structure are electrical machines, depending wholly upon electromotive force for their activity.

The last of the series of experiments by which this theory is claimed to have been scientifically proved was conducted last week in a South San Francisco stockyard, when Dr. Atkins and his co-workers, Dr. E. A. Lewis and Dr. H. W. Hunsaker, registered on a galvanometer electrical currents in the heart and brain of living sheep. Tiny electrodes attached to the testing instrument by a long wire were inserted directly into the heart and brain of the animal that had been prepared for vivisection by the injection of cocaine into the spinal column, and instantly, as the sharp points pierced these vital organs, the needle of the delicate machine quivered and oscillated as it registered in millivolts the alternating currents of electricity.

If Dr. Atkins is right in what he believes he has proved, man and his lower kindred, the animals, are complicated electrical machines with a lot of smaller machines within the large one.

Dr. Atkins as far back as last September registered electrical currents in the lungs of a sheep, and later demonstrated in the same way that the liver, kidneys and other organs are also run by electricity. The lungs contain by far the most positive electric energy. This, Dr. Atkins explains, is because the oxygen drawn in the lungs is chemically combined with the blood in this organ. This is done by electro-chemical action, according to Dr. Atkins. Chemical action is nothing but electrical action, he argues, and in the lungs begins the process of generating the electricity with which the body is stored, and which, in fact, is the life of the body.

ESTIMATED COST OF MUNICIPAL LIGHTING.

At a meeting of the Board of Estimate of the City of New York on February 10 Mayor McClellan presented the preliminary report of the commission he appointed to prepare plans for municipal lighting plants. The members of the commission are Cary T. Hutchinson, George F. Sever and Nelson P. Lewis. The report is an elaborate one, but deals only with plants for lighting the streets, parks and public buildings.

The estimated cost of complete plants for providing 6,000 electric arc lamps and 250,000 sixteen candle-power incandescent lights is $4,100,000, exclusive of the cost of real estate. The commissioners in their report say that they have decided on two sites for power houses, but the locations are not made public. They ask permission to consult privately with the Comptroller in order that they may obtain options on the land. The Board of Estimate ordered the report in full printed and requested the Comptroller to confer with the committee about the purchase of sites for power houses.

The report says that the total cost of a power station with 10,000 kilowatts power, exclusive of real estate, will be $1,250,000, and the cost of high pressure cables, substations and all details for 6,000 arc lights and 250,000 sixteen candle-power incandescent lights, $2,850,000.

The estimated cost a year of arc lamps, including interest on bonds and depreciation of plant, is placed at $75.40. The cost a year of the sixteen candle-power incandescent lights is fixed at $5.15. The total annual cost of operating the proposed plants is estimated in the report at $906,000. The estimates do not include any cost for the construction of ducts or rental for them, because the city has the right to use the ducts of the private subway companies.

The general plan suggested in the report provides for a power station for Manhattan and the Bronx, one for Brooklyn and Queens and a third for Richmond. There is no reference to extending the system to provide light for private consumers.

According to the report the estimated cost of lights is less than the city is now asked to pay to private companies. The present cost of arc lights is from $130 to $145 a year, and the Commission's estimate of the cost by a city plant is $75.40. The average cost of street lamps is now $16 a year, while the Commission's estimate of the cost to the city of sixteen candle-power incandescent lights is $5.15 each.

THE INSTITUTE DINNER.

The annual dinner of the American Institute of Electrical Engineers was held in the grand ball-room of the Waldorf Astoria, New York City, on the evening of February 8. The room was appropriately decorated for the occasion. Miniature electric lamps were everywhere in evidence and numerous Cooper Hewitt mercury vapor lamps were placed around the balcony.

The members and guests numbering about 300, met in the Astor gallery, where the famous painting of Dr. Gilbert, and a beautiful bust of Galileo Ferraris were inspected.

The dinner was served promptly at 7:30. Toward the close President John W. Lieb, Jr., greeted the guests in the name of the Institute, and took occasion to make a few apt remarks on the progress made in the industry.

Mr. T. C. Martin was introduced and acted as toastmaster.

Mr. Frank J. Sprague was then called upon and responded to the toast of "Art and the Men." He reviewed the struggles in the early days of the electrical industry and among other things said:

"Looking back these nearly twenty years, I am reminded of the cry of the prophet, 'Oh, ye of little faith,' and yet I for one, and I think I may speak for most of the others, would not have had it otherwise, for let me tell you, my younger brethren, whether it be on the battle field or in civil pursuits, there is no victory so sweet as that wrung from almost certain defeat, and if you need encouragement in present or future struggles, let me bid you ask of the living and the dead the record of 1879 to 1888. They will tell you of cynicism, ridicule and unbelief, of unremitting labor and disappointment, of poverty, sickness, wreck and ruin, but they will also tell you of their inspirations, of exalted moments, of hopes realized, of victories won."

Mr. Leo Daft followed Mr. Sprague, his address being "These Twenty Years."

Mr. Herbert H. Vreeland responded to he toast of "The Broomstick Train."

Mr. Lewis Buckley Stillwell, in his address, entitled "Traction Above Ground nd Under," said:

"As a public work the construction of the New York Subway has been an object lesson of great significance and value. From start to finish it has been carried out under the direction of the Rapid Transit Commission, without fear or favor, and with an eye single to the public good. No money has been wasted and not the slightest scandal of any kind has attended its progress. The work is a splendid monument to the Commission and to its engineers. The community has received maximum benefit at minimum cost. At the same time the enterprising men who ventured their capital in the enterprise, at a time when its success was generally considered doubtful, have reaped a handsome reward to which they are in every sense of the word entitled."

The toast on "Other Uses of Electricity," was responded to by Gen. A. W. Greeley. He spoke interestingly of the work that had been and was being done by the United States Army Signal Corps.

The following gentlemen were seated at the speaker's table. John W. Lieb, Jr., T. C. Martin, F. J. Sprague, L. B. Stillwell, C. A. Coffin, C. C. Schneider, W. G. Ross, James Gayley, Nikola Tesla, Elmer A. Sperry, General Greeley, Leo Daft, C. F. Scott, R. W. Pope, Gen. Eugene Griffin, E. W. Winter, H. H. Vreeland, T. C. MacCarter, Dr. A. R. Ledoux, Dr. F. B. Crocker, W. B. Potter, C. G. Curtis, W. J. Wilgus, F. D. Underwood, H. H. Westinghouse, Dr. S. S. Wheeler, G. W. Stockley, John R. Freeman, H. Ward Leonard and B. J. Arnold.

New York Electrical Society.

The 248th meeting of the Society will be held in the Assembly Room of the Metropolitan Street Railway Association, 761 Seventh avenue, this (Wednesday) evening, February 15, at 8 o'clock. The room is on 50th street, one block east from the Subway station, and one block west from the 6th avenue elevated station. Mr. Herbert H. Vreeland, president of the New York City Railway Company, will address the Society on "Electric Railway Operation in a Great City."

on's 58th Birthday.

Mr. Thomas A. Edison celebrated his 58th birthday Saturday in his Orange, N. J., home. Mr. Edison's progress toward recovery is steady, but his family and his physician are shielding him from all excitement.

Central Electric's Building Burned.

A six-story brick building at Nos. 264-270 Fifth avenue, Chicago, occupied by the Central Electric Company, was practically destroyed by fire on Saturday, causing a loss of $600,000.

Proposals Invited.

The Bureau of Supplies and Accounts of the Navy Department at Washington, D. C., is inviting sealed proposals until March 14 for furnishing the Mare Island and Puget Sound Navy Yards with the following: Schedule 79, insulating tape, electrical wire, transformers; schedule 82, incandescent lamps, electrical cable, tape and globes. Blank proposals will be furnished on application to the Bureau or to the navy pay offices in San Francisco, Cal., and Seattle, Wash.

On March 3 the supervising architect of the Treasury Department will open bids for the installation of a conduit and electric wiring system in the United States Marine Hospital at Savannah, Ga. For further information address James Knox Taylor, supervising architect, Washington, D. C.

Sealed proposals for installing electric elevators in the new quartermaster's storehouse at Omaha, Neb., will be received until February 28. Full information furnished on application to Lieut.-Col. J. E. Sawyer, Omaha, Neb.

Sealed proposals for installing two electric elevators in the Portsmouth, N. H., Navy Yard, will be received until March 11. Plans and specifications may be seen at the office of the commandant of the yard, or at the Bureau of Yards and Docks, Navy Department, Washington, D. C.

Wants a Second-hand Engine and Boiler.

We are in receipt of the following: "In a copy of ELECTRICITY I noticed several advertisements of machinery, and being in the market for an engine and boiler, large enough and qualified to run a 30 kw. dynamo, can you give me the address of a place where I can get a second-hand engine and boiler? E. M. Hanscom, Milton, Fla."

Standard Underground Cable Company's St. Louis Office.

The Standard Underground Cable Company, owing to general developments in its rapidly growing business in the southern and southwestern territory, has decided to establish in St. Louis its southwestern sales office. Mr. E. J. Pietzcker, who has been attached to the Western Sales Department with headquarters in Chicago for the past two years, has been appointed manager of the new sales office and will be located at 521 Security Building, St. Louis.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED FEB 7, 1905.

Electric Railways and Appliances.

781,639. Railway-Signal. Frank L. Dodgson, Rochester, N. Y., assignor, by mesne assignments, to the General Railway Signal Company, Gates, N.Y. Filed March 27, 1903.

781,661. Stringer-Support for Electric Third Rails. Frank E. Kinsman, Plainfield. N. J. Filed July 28, 1903.

781,721. Guard for Trolley-Wheels. Merwin M. Hart, Chicago, Ill. Filed April 15, 1904.

781,757. Automatic System of Signaling for Electric Railways. Samuel M. Young, New York City. Filed Nov. 15, 1904.

781,842. Multiple-Contact Trolley. Lewis M. McBride Denver, Col. Filed July 5, 1904.

781,962. Trolley. Edward H. Miller, Pittsburg, Pa., assignor of one-half to Harry Carr, Harry E. Weaver and Louis H. Rosenthal, same place. Filed Sept. 30, 1904.

781,991. Car-Fender. Louis A. Bechtel, Jr., Benwood, W. Va. Filed Sept. 23, 1904.

782,007. Third Rail. Leonard T. Crabtree, Crandon, Wis. Filed April 14, 1904.

782,100. Signaling Apparatus for Electric Railways. Walter C. Bethel, Seattle, Wash. Filed Nov. 4, 1904.

782,195. Trolley-Pole Controller. Clarence V. Greenamyer, Los Angeles, Cal., assignor to William Hyman Holabird, same place. Filed Feb. 4, 1903.

Electric Lights and Appliances.

781,937. Electric-Arc Lamp. Albert G. Davis and John E. Hubbell, Schenectady, N. Y., assignors to the General Electric Company. Filed July 7, 1904.

Electrical Machinery and Apparatus.

781,638. Electric Ingot-Extractor. James R. Spear and Willie H. Baltzell, Pittsburg, Pa. Filed May 17, 1900.

781,706. Alternating-Current Generator. Emil Ziehl, Berlin, Germany. Filed Sept. 30, 1904.

781,785. Circuit-Controller. Louis Pfingst, Boston, Mass., assignor to Pfingst Electric Manufacturing Company, Kittery, Me. Filed April 4, 1904.

781,931. Means for Protection Against Short Circuits. Charles E. Barry, Schenectady, N. Y., assignor to the General Electric Company. Filed July 15, 1904.

781,932. Alternating-Current Apparatus. Edward Bennett, Pittsburg, Pa., assignor to George Westinghouse, same place. Filed Oct. 13, 1902.

781,945. Electric Meter. Edward S. Halsey, Chicago, Ill., assignor to the General Electric Company. Filed March 13, 1902.

781,968. Dynamo-Electric Machine. Joseph Sachs, Hartford. Conn. Filed Sept. 19, 1903.

781,989. Controlling Mechanism for Self-Propelled Vehicles. Augustus A. Ball, Jr., Lynn, Mass., assignor to the General Electric Company. Filed Sept. 4, 1902.

781,993. Circuit-Closer. Walter J. Bell, Los Angeles, Cal., assignor of one-half to Leon F. Moss, same place. Filed Oct. 9, 1903.

782,082. Coin-Freed Electric Meter. Frank Holden, Rugby, Eng., assignor to the General Electric Company. Filed March 3, 1903.

782,038. Thermal Cut-out. Charles E. Lockwood and George A. Lutz, New York City. Filed Oct. 28, 1903.

782,054. Induction-Motor. Henry G. Reist, Schenectady, N. Y., assignor to the General Electric Company. Filed July 11, 1904.

Telephones and Telephone Apparatus.

781,793. Sanitary Attachment for Telephones. Isaac M. Slocum, Boston, Mass. Filed June 22, 1904.

781,797. Telephone-Receiver. Axel R. Thollander, Chicago, Ill. Filed Oct. 1, 1904.

781,888. Telephony. Isidor Kitsee, Philadelphia, Pa. Filed April 4, 1901.

Miscellaneous.

781,762. Electrical Dental Furnace. Luther L. Bosworth, Cleveland, O. Filed March 5, 1904.

781,795. Storage-Battery Electrode. Elmer A. Sperry, Cleveland, O., assignor to the National Battery Company, Buffalo, N. Y. Filed Jan 27, 1904.

781,805. System of Electrical Distribution. Theodore Bodde, Schenectady, N. Y. Filed Nov. 18, 1903.

781,873. Wireless Telegraphy. Patrick B. Delany, South Orange, N. J. Filed July 10, 1903.

781,919. System of Electrical Distribution. Charles W. Stone, Schenectady, N. Y., assignor to General Electric Company. Filed Sept. 30, 1901.

782,066. omatic Alarm-Telegraph. Albert D. Shaw, New York City. Filed April 15, 1904.

782,131. Electric Temperature-Alarm. Cowan P. Heple Smithton, Pa. Filed Feb. 20, 1904.

THE TELEPHONE WORLD.

Buffalo Independents Meet.

The February meeting of the Buffalo district of the New York State Independent Telephone Association was held in that city about ten days ago. Practically all of the Independent telephone companies operating in the district were represented.

The growth and financial success of the Independent telephone companies in that district is said to be flattering to the organizers, and much new construction is planned for the coming year.

Telephone Improvements in Wisconsin.

A large amount of construction work will be done on Independent long-distance telephone lines in Wisconsin and the Northwest the coming summer, according to a statement made by Manager Bowee of the Consolidated Company of Minneapolis.

Mr. Bowee stated that his company built 600 miles of new line last summer, including the line to Winona and La Crosse, and expects to push on to Madison and other cities in the State the coming season.

The New York Telephone Company has announced a general reduction of 25 per cent. on all its charges for service to the various departments of the municipal goverment. The cut rate takes effect from January 1, 1905, on all city contracts, both for unlimited and measured rate service. No new concession has been made yet to private subscribers, the 25 per cent. reduction applying only to telephone installations in connection with the various branches of the city's official business.

The Southwestern Home Telephone Company of Redlands, Cal., has filed articles of incorporation in San Bernardino. The company will build a line from Redlands, Beaumont, Banning, San Jacinto and Hemet, and thence along the line of the Southern Pacific to Yuma, Ariz. The work of constructing this line is already under way and when completed will be the only telephone line from California to connect with the Arizona lines.

The Georgia-Alabama Telephone Company, which operates the Dawson telephone exchange, is making extensive improvements in the system. In consequence of these improvements the rates are to be increased from $1.50 to $2 per month for residence 'phones, and from $2.50 to $3 for business houses and offices.

A report from Philadelphia states that the Keystone Telephone Company reorganization plan is said to be about completed and provides for a new bond issue to take the place of the present bonds and preferred stock.

The Long Distance Telephone Company of Kansas City has filed a mortgage in Nevada City, Mo., for $1,500,000 to the Commonwealth Trust Company. The company is building a line from Joplin to Kansas City.

The Michigan State Telephone Company is at work on the construction of a telephone line from Escanaba to Foster City, a distance of 40 miles.

Another Independent Telephone Association Organized.

The West Kentucky and Tennessee Independent Telephone Association was lately organized at Hazel, Ky.

The association consists of seven Independent telephone companies, with a total of 320 miles of lines. They are as follows: The Citizens, the Marshall County, the Calloway County, the Lily, the Valley and the Farmers' and the Rural Telephone Company. All of these companies were represented by delegates at the meeting and have made arrangements to extend their lines all over the country. Their lines now reach Sedalia and in a short time will enter Mayfield, where the stockholders of the company will have free communication over the entire system. Capable and reliable business men are at the head of this new association. Dr. W. B. Stokes is the president, B. B. Pullen secretary, and J. V. Boyd treasurer, all of Farmington, besides many other good business men are stockholders.

After many weeks of preparation the Livingston County Telephone Company has now completed its exchange in Geneseo, N. Y. The company has spared no pains in installing the office equipments, and the thoroughness of the work indicates that the Geneseo exchange will not lack for business. The sharp competition which is already noticeable between the branch of the Bell Company there and the County Telephone Company bids fair to make the service better than any that has heretofore been given.

At a meeting of the stockholders of the County Telephone Company of Herkimer, N.Y., recently the following were elected officers: President, Robert Earl; vice-president, James Conkling; secretary, Charles H. Poole; treasurer, W. I. Taber; engineer, Edward Cline. The company has 'phones in Ilion, Frankfort, Mohawk and Herkimer.

The Yellville Telephone Company of Yellville, Marion County, Ark., was lately given a charter. The capital stock is $150,000, all subscribed, and the company has announced its intention of constructing and operating telephone plants in several of the towns of Marion, Boone and Baxter Counties. The incorporators are V H. Weart, L. M. Weart, S. L. Brooksher, R. R. Brooksher and G. A. Ward.

The Caddo Cave Telephone Company, with a capital stock of $20,000, has been incorporated to build telephone lines in Montgomery and Garland Counties, Ark. The place of business is at Johnson, but the office of the company is at Ghent. The incorporators are J. Johnson, G. A. Driggins, F. J. Hughes, J. L. Thomas and J. A. Johnson.

At a meeting of the stockholders of the Camden, Mich., Rural Telephone Company the capital stock of the company was increased to $25,000. This company was incorporated about 18 months ago.

The annual convention of the Ohio Independent Telephone Association will be held in Columbus some time next month. Frank L. Beam, of Columbus, is president of the association.

Iowa's Telephone Record.

According to the United States Census Bureau's Bulletin, covering the development of the telephone business up to the close of 1902, Iowa is shown to have the largest growth in the matter of rural lines, having an average of 13.6 miles of wire and 20 telephones for each rural line.

It has 33 per cent. of all the Independent rurul lines of the country, which use 25 per cent. of the total mileage of wire needed for such telephones.

The total number of lines operated in rural districts is given as 21,577. Of this number 15,598, or 73 per cent., were lines owned and operated by commercial systems; 994, or 4.6 per cent., were the mutual systems, all of which are rural, and the remaining 4,985, or 23 1 per cent., were Independent farmer or rural lines. The total length of wire is given as 259,306 miles, and the total number of telephones 266,968, giving an average of about 12 telephones to each line and less than one mile of wire per telephone. Five States, among which was Iowa, have 68.9 per cent of all these lines.

Iowa is shown to have 120,017 telephones of all kinds, which is one to every 19 residents of the State.

Farmers of Belle Township, Edmunds County, S D., have organized the Edmunds County Mutual Telephone Company. They have a barbed wire telephone system of twelve miles, and by co-operation hope to extend the system and to fill in any gaps that may exist in neighboring communication.

The Kansas Independent Telephone Association held its annual meeting in Topeka February 8 and 9. The officers of the association are: President, A. A. Godard, Topeka; vice-president, J. M. Doyle, Belleville; treasurer, J. W. Smith, Minneapolis; secretary, C. E. Wells, Marion.

The farmers in the neighborhood of Maize, Kan., are desirous of installing a telephone system for their own use, to be connected with the system in Wichita. To that end they want a franchise for a central office and switchboard, to be located at the latter place.

Telephone Incorporations.

The West Richfield Telephone Company, West Richfield, O. Capital stock, $10,000. Incorporators: Edwin L. Carter, James B. Stauffer, J. B. Kennedy, M. L. Newton and Allen S Prickett.

The Santa Clara Valley Home Telephone Company. Capital stock, $75,000. Directors: C. F. Guthridge, C. L. Zahn, D. F. Boyce, C. P. Platt and A. Wright, all of Los Angeles.

The American Rural Telephone Company, Apache, Okla. Capital stock, $10,000. Incorporators: J. H. Mallory, L. Beckman and R. N. Mallory.

The Home Telephone Company, Grand Meadow, Minn. Capital stock, $50,000. Incorporators: C. F. Greening, W. A. Nolan, Martin Axness and W. P. Lewis, all of Grand Meadow.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Albany, N. Y.—The Franklin Springs Electric Light Company, with a capital of $5,000, has been incorporated by Frederic De W. Smythe and Delos De W. Smythe, of Utica, and E. B. Stanley, of Clinton, to operate in the towns of Kirkland, New Hartford and Marshall and the village of Clinton.

Clear Lake, Minn. —This city is negotiating for an electric light plant.

Elko, Nev.—The Elko Electric Light & Power Company has been incorporated by John G. Hylton, A. W. Hesson, R. H. Mallett and others with a capital of $100,000.

Goodwater, Ala.—Arthur Salmon, of Dadeville, has secured a franchise to construct an electric light plant here.

Harrison, O.—A. L. Rich & Co. have increased the capital of the Harrison Waterworks & Electric Light Company to $40,000. Improvements are contemplated.

Keyser, W. Va.—The Keyser Electric Light Company contemplates enlarging its plant. F. M. Reynolds is president.

Lacrosse, Kan.—This city has under consideration the voting of bonds to the amount of $25,000 for the purpose of establishing a waterworks and electric light plant.

Lawrenceburg, Ky.—The committee appointed by the Commercial Club believes that a contract will soon be made which will insure the installation of an electric light plant within the next few months.

Lexington, Mo.—Charles Reynolds, C. B. Leach and E. H. Burr have incorporated the Lexington Gas & Electric Company with a capital of $80,000.

Liberty, Mo.—The electric light plant was lately wrecked by the explosion of a boiler.

Loveland, O.—The people of this city are trying to secure an electric light plant.

Lytton, Ia.—A plan is on foot for the lighting of this place from the electric plant at Sac City.

Madison, Mo.—Local capitalists are agitating a project to operate an electric light plant here.

Memphis, Tenn.—The Merchants' Light & Power Company, capitalized at $500,000, has been incorporated by L. Bry of St. Louis, Hugh Pettit and R. W. Uhlman to erect an electric light plant.

Meridian, Miss.—A franchise has been applied for by C. H. Dabbs, R. Cahn, H. L. McKee and J. T. Chalk to build and operate an electric light and gas plant.

Montrose, S. D.—Mark Donahue and P. G. Williams have purchased an electric light plant which will be installed as rapidly as possible.

Niles, O.—The city electric lighting system is inadequate and the purchase of a new engine is necessary.

Oakdale, Pa.—The electric lighting plant was recently destroyed by fire. Loss, $5,000.

Palmyra, N.Y.—The Palmyra Gas & Electric Company has been incorporated with a capital of $25,000.

Plaquemine, La.—The Plaquemine Electric Light & Power Company, with a capital of $30,000, has been incorporated by H. J. Savage, M. Dick and V. M. Barber, and proposes to erect a system of electric lights for this town.

Rochelle, La.—The electric light plant, ice factory and machine shops owned by the Louisiana Lumber Company were lately destroyed by fire.

Royalton, Minn.—It is the intention of the council to at once commence the installation of an electric light plant.

San Angelo, Tex.—U. G. Taylor of this place expects to install at an early date an electric light plant at Angelo Heights.

San Jose, Cal.—A committee of the assembly on public buildings and grounds came here recently and proceeded to Mount Hamilton for the purpose of looking into the need of an electric lighting system at Lick Observatory and whatever else is needed. A bill for an appropriation of $10,000 for this purpose has been introduced by Assemblyman Paul J. Arnerich. It is not known whether the proposal will be to establish a plant on the mountain or to connect the system that may be installed there with the Blue Lakes system.

Seminary, Miss.—The Mason Lumber Company, whose plant is located at Pratt Station, half a mile north of here, will put in a large electric lighting plant at an early date and furnish lights for this place.

Spearfish, S. D.—The Homestake Mining Company has purchased the Spearfish Electric Light & Power Company's property which furnishes light and heat for this city.

St. Louis, Mo.—The North American Company will expend $2,000,000 on improvements to the plant of the Union Electric Light & Power Company.

Wauette, Okla.—Captain Hamblin and Phil Hall of Shawnee, I. T., capitalist and promoter, have been looking over the ground here for the purpose of securing a franchise for an electric light plant and waterworks system. They have met with much encouragement.

Watkins, N. Y.—The electric light plant of the Watkins Consolidated Gas & Electric Light Company was destroyed by fire. The loss is covered by insurance.

STREET RAILWAYS.

Baltimore, Md.—The United Railways & Electric Companies will erect a power house on Pratt street to cost $75,000. John Walters is the contractor.

Boise, Idaho.—W. E. Pierce states that the local company which is being formed for the purpose of building an electric railroad from here to Pearl means business and that the work of surveying for the line will be commenced as soon as the weather will permit.

Clarksville, Tenn.—The Clarksville Electric Street Railway Company has filed an amendment to its charter changing its name to the Clarksville Railway & Light Company, and increasing its stock from $20,000 to $250,000. The amendment authorizes the extension of its lines to the Kentucky State Line, New Providence, Durbars Cave and other places.

Clyde, N. Y.—Outside capitalists having promised to build an electric road between here and Sodus Bay to cost approximately $250,000, providing the people of this section would subscribe for $20,000 worth of the stock, at $100 a share, an effort is being made to meet these requirements.

Corry, Pa.—A trolley line will be run from this city to Columbus, O.

Des Moines, Ia.—J. W. Blesee and several men of this city have a project for building an electric road from here to Kansas City, Mo., via Winterset Greenfield, Carbon and Villisca.

Joplin, Mo.—The Spring River Power Company of this city announces that it will build an elctric line from Baxter Springs to Galena, a distance of eight miles. Most of the right-of-way has been secured, and work of laying the rails will begin at once. The line will connect at Galena with the Southwest Missouri electric railway.

Kennett Square, Pa.—A new trolley line from here to Coatesville, 13 miles, is projected.

Lafayette, Ind.—The Lake Erie & Western Railroad Company has decided to start the work of electrifying a number of its lines in this State. The company expects to spend $200,000.

Noblesville, Ind.—The Indianapolis, Hartford City & Celina Traction Company has asked the city council for a 50-year franchise.

Paducah, Ky.—Jeff Read of this city is one of the promoters of a proposed electric interurban road between Paducah and Cairo, Ill.

St. Joseph, Mo.—A franchise has been granted to the St. Joseph & Maryville Electric Railroad Company, to build a line from Andrew to Buchanan Counties.

Texarkana, Ark.—The Texarkana Traction Company contemplates the erection of a boiler house and the installation of new machinery and boilers.

Warrenton, Va.—The people here are discussing a project to build a trolley line from Fauquier County to Deep Water on the Potomac River.

POWER PLANTS.

Durango, Mex.—Thomas Wilson has been investigating the situation in the western part of the State of Durango, with a view to establishing an electric power plant in that region for furnishing power for mines.

Oaxaca, Mex.—Charles A. Hamilton, who has been busily engaged on the project for the erection of a large smelter in this city, is now working on a plan for putting in a vast electric power plant in the district of Ejutla, in the State of Oaxaca.

San Cristobal, Mex.—John J. Moylan, a capitalist and mine operator of the City of Mexico, is preparing to establish an electric power plant near this place. The proposed plant will be located on the San Cristobal River and will afford power for operating hoists and other machinery at the Poder de Dios mine.

BIDS WANTED.

Columbia, Tenn.—George P. Webster represents a company of this city that is in the market for a 75 hp. Corliss engine.

Gum Neck, N. C.—F. F. Owens, Box 47, is in the market for a 10 hp. engine and 12 hp. boiler.

Havre de Grace, Md.—F. Schnitzlein of this city is in the market for a 12 hp. engine and a 40 hp. upright boiler.

Lawton, Okla.—The Lawton Ice Company will be in the market next June for electrical equipment.

Worcester, Mass.—The Worcester Electric Light Company is in the market for a new battery of 12 boilers, to aggregate 3,000 hp.

NOTES FOR INVESTCRS.

Latest quotations for copper are: Electrolytic, 15⅛@15¼c.; Lake 15¼@15⅜c.; casting, 14⅞@15c.

In a circular issued on Boston Elevated, Hornblower & Weeks show that the average gain in the gross earnings of the system for the last ten years has been 6.1 per cent.

The American Railways Company (Philadelphia) declared a regular quarterly dividend of 1½ per cent. on the capital stock, payable March 15, to stockholders of record February 28.

The Southern New England Telephone Company has made application to the Connecticut General Assembly for permission to increase its capital stock from $5,000,000 to $10,000,000.

The report of the Interborough Rapid Transit Company of New York for last quarter showed increased net earnings due to the subway. The company's gross earnings for the three months increased $815,145.

The Philadelphia Rapid Transit Company has sold $10,000,000 bonds of the Market Street Elevated Railroad Company at par to Drexel & Co. The bonds bear 4 per cent. interest payable semi-annually and run 50 years.

The syndicate which took charge of the issue of Brooklyn Rapid Transit bonds has disposed of all the bonds. It is understood that the Brooklyn Rapid Transit Company will hereafter issue no bonds having the convertible clause.

The $7,500,000 bonds of the recently organized Baltimore Electric Power Company, which will probably absorb the Maryland Telephone Company, have been underwritten by the Northern Trust Company, of Philadelphia, and the Central Trust Company, of Maryland.

Suit has been instituted in the Court of Chancery at Trenton, N. J., to set aside two voting trusts of the Augusta-Aiken Railway & Electric Company which owns and operates the entire street railway and electric lighting systems of Augusta, Ga. The complaining stockholders charge a general mismanagement of the company's affairs.

It is stated at New Haven that negotiations for the purchase by the New Haven Railroad Company of the Connecticut Railway & Lighting property, consisting of 175 miles of single track and several gas and electric light companies, and capitalized at $9,464,100 common stock and $5,535,900 preferred, are still far from consummation.

The reorganization committee of the New Orleans Railways Company, of which Otto T. Bannard is chairman, has announced a plan of reorganization through the formation of a new company with $30,000,000 of 30-year 4½ per cent gold bonds, $10,000,000 of 5 per cent. non-cumulative preferred stock and $20,000,000 of common stock.

The Hamilton Gas & Electric Company is the name of the consolidation of the Hamilton Gas & Coke Company, the Hamilton Electric Light Company and the Hamilton-Otto Coke Company, all of Hamilton, O. The new company has made a mortgage to secure $1,000,000 five per cent. 30-year bonds and has a capital stock of $1,060,000

Stockholders of the Gas & Electric Company, of Bergen County, N. J., will vote February 23 on leasing the property for 999 years to the Public Service Corporation, which will guarantee dividends on $2,000,000 stock, 2 per cent. for two years, 2½ per cent. for one year, 3 per cent. for two years, 4 per cent. for four years and 5 per cent. thereafter.

Joints Made Absolutely Tight and Durable by Patent Corrugated

COPPER GASKETS,

Furnished in all shapes and sizes for flanged PIPES, CYLINDERS, CHESTS, etc.

U. S. MINERAL WOOL COMPANY,
143 Liberty Street, New York.
BOURNE & KNOWLES MFG. Co., Cleveland, Ohio.

ECONOMIC ENGINEERING

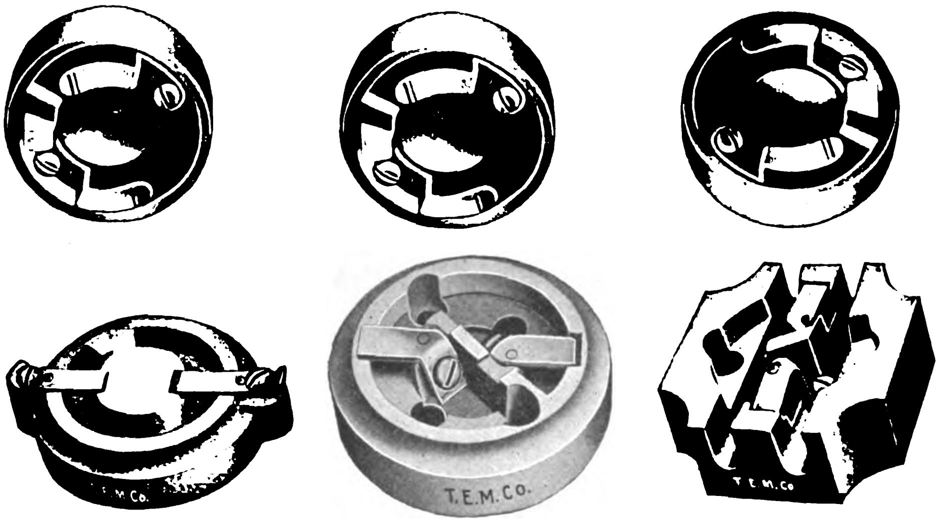
Designing and Building Special Machinery

Elevating, conveying and storing materials in any shape or form—from one point to another, high or low—is a specialty with us.

In designing, erecting and installing complete plants we have gained much valuable engineering experience. This expert knowledge is at the disposal of any prospective purchaser or engineer that's interested.

NEW YORK, 106 Graham Bldg. PHILADELPHIA, 716-718 Fidelity Mutual Bldg. (3) PITTSBURG, PA., 701 Empire Bldg.

THE AULTMAN COMPANY, CANTON, O.



NEW FUSELESS ROSETTES

Appreciated by all who have to do with wiring. May be fitted with cord and snapped on after the base is in position by merely a quarter turn of the wrist. Notice the stop in the cap. It can be put on only one way, so that in arc-light work there is no possibility of reversing the current by taking off the rosette cap.

CAPS INTERCHANGEABLE. FIT EITHER STYE OF BASE. Hole in cap takes new code cord. Sample sent prepaid.

Manufactured by

THE TRUMBULL ELECTRIC MFG CO.,
High Grade Electrical Specialties,
PLAINVILLE, CONN.
New York Office, 136 Liberty Street.

"ELECTRICITY,"

IS ONLY $1 A YEAR.

Pittsburg Sewer Pipe & Conduit Company

Manufacturers of

VITRIFIED CLAY CONDUITS

IN 1, 2, 3, 4 AND 6 DUCT.

Superior Conduits for underground wires a specialty.

General Office and Factory:

EDITORIAL NOTES.

The Tantalum Lamp.

Inventors and scientists, especially in Germany, are constantly at work trying to perfect the incandescent electric lamp. And sad to relate, although the incandescent lamp with carbon filament, as seen to-day, is a work of genius, it can stand perfecting in the way of heat loss and length of life.

Elsewhere in this issue will be found a short article on a new lamp recently brought out in Germany. In this lamp the carbon filament has been discarded and instead a filament of the metal tantalum is made use of. This filament is over two feet in length and is supported by a special form of frame and bulb, the extremities of the filament being connected with the foot of the lamp by means of platinum strips.

Referring to the subject the "Mechanical World," an English publication, states that experiments show that the tantalum lamp consumes about 50 per cent. less current at the same voltage, with the same intensity of light and the same useful life, that the carbon filament lamp does. The useful life of the lamp averages between 400 and 600 hours at 1.7 watts per British candle-power, while under normal working conditions the average life ranges from 800 to 1,000 hours.

* * *

Avoid Socialistic Tendencies.

The bids for building the garbage destructor plant, which is expected to furnish electric light for the Williamsburg Bridge and neighboring school-houses, were opened last week. The lowest bid submitted was $31,000. This bid is for the buildings, but does not include the necessary electrical machinery and apparatus.

The question as to the advisability of the city owning and operating its own plants is still being warmly discussed pro and con. A few days ago the "Wall Street Summary" referred to the question editorially: It said:

"We have our doubts, as to the wisdom of the action taken; and believe that all this agitation and public clamor will soon die out and that a rational view will be taken of the subject. We are yet to be convinced that municipal ownership in a city like ours is wise or prudent. The principle involved may be popular, but the practicability of the policy is unquestionably very doubtful. We do not believe it is possible for the city to operate any public electric or gas plant, and eliminate therefrom political methods and partisan manipulation. We feel that places will be created, and that the demand for sinecures will be so strong, that in a short time the operation of this public utility will become a hot bed of pernicious political activity. When that time arrives, as it surely will, the present sentiment, so strongly in favor of the step taken, will change to a demand for a return to private ownership. If it were possible to establish safeguards which would insure business methods in the operation by the city, of its public lighting plants, then the step just taken would be in the right direction. As that is not probable, or will not be done, then we are not disposed to become enthusiastic over the apparent possibilities now in sight."

The above opinion agrees with that expressed by us in these columns only two weeks ago. The "Wall Street Summary" believes that the real remedy consists in curbing by means of proper legislation the private corporations now furnishing light, for it concludes as follows:

"Legislation to curb those who may

take undue advantage of the franchises they possess, is one thing; but to jump from the 'frying pan into the fire' is another. We know it is possible to safeguard our city against the wrongs that may be done by corporations, and to that possibility and necessity our public officials should direct their attention rather than to the opportunity of 'tickling the fancy' of those who possess socialistic tendencies, and toward providing political 'pap' and 'graft' to the hungry horde who are constantly watching and waiting for something to 'drop into their laps.' The authorities may be sincere; but they surely are not acting wisely. When so much is involved, and millions are to be expended, action on impulse, though prompted by public clamor, becomes a criminal offense."

* * *

Radium Research. Hardly a day passes without something new being added to our information in regard to radium. The very nature and state of our knowledge concerning it are sufficient to account for this, seeing that the leading scientific minds in all countries are engaged in the investigation of this, the most fascinating of all scientific matters of the hour. But it is not only the leaders in scientific circles who are engaged in this research; many an unknown student is occupied in retirement in earnest endeavors to throw some new light to help in the unraveling of the skein of mystery. The multitude of papers and contributions on radium and radio-activity which were brought before the last meeting of the British Association for the Advancement of Science afforded a good example of the practical efforts which are being made by students both great and small.

A communication of considerable interest came before the London Physical Society recently regarding the action of radium on the electric spark. The authors, Dr. R. S. Willows and Mr. J. Peck, found that in certain cases the spark from a Wimshurst machine is extinguished by the action of the radiations from radium, and that the current passing is decreased. It seems that the action is altogether different according to the direction of the discharge. When a spark gap longer than 2 centimeters was used and the larger knob of the machine employed was made positive, the radiations were found to have practically no influence. But when the smaller knob was the positive, the radium in most cases extinguished the spark. It is stated that the phenomenon is due to the action of the B rays. Roentgen rays do not produce this effect, even if their ionizing power at the spark-gap is some thousands of times greater than that of the radium; Lenard rays are, however, effective. Prof. F. T. Trouton, who spoke in the discussion at the Physical Society, mentioned the fact that the action of the radium depended upon the direction in which the current was passing, and said that he was quite unable to see an obvious explanation of this phenomenon.

◆

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

A loss of $764 per day in the net earnings of the Cleveland (O.) Electric Railway Company is reported to be the result of recent three and four cent fare experiments.

◆

Among the recent bills introduced in the New Jersey Legislature was one providing for municipal ownership of electric light plants in all cities of the first class.

◆

Arrangements are being made in San Francisco, Cal., for the installation of a plant for communication by wireless telegraphy with Panama by a direct coast route and by way of the East via Denver, Kansas City, Chicago, New York, Key West, Porto Rico and Cuba. Following this, direct communication will, it is said, be perfected between San Francisco, the Philippines, the Orient and the Hawaiian Islands.

◆

Reports from Pittsburg, Pa., Gloucester, Mass., and Barre, Vt., state that electricity is being used successfully in those places for thawing out water pipes.

◆

Experiments were made last week between Paris and London with the Pollak and Virag system of telegraphy. The inventors claim that with their perfected apparatus 40,000 words an hour can be transmitted, requiring the aid of six clerks. As will be remembered in this system the messages arrive written out and not in Morse characters.

◆

Another Atlantic cable is to be laid by the Commercial Cable Company. Bids for the cable and its placing have already been received. The route has been decided, and it is expected that the new cable will be in operation during the coming summer. Clarence H. Mackay said that no new stock would be issued on this cable and that the cost had been met by the Mackay companies to keep the reserve fund of the Commercial Cable Company intact. The new cable will be of high speed and will embody the latest discoveries in electrical work.

◆

The 194th meeting of the American Institute of Electrical Engineers will be held in the Chapter Room, Carnegie Hall, 154 West 57th street, New York City, Friday, February 24, at 8:15 P.M. The following paper will be presented and discussed: "Two-Motor vs. Four-Motor Equipments," by N. McD. Crawford, general manager of the Hartford (Conn.) Street Railroad Company.

◆

The telegraph department of a Western railroad is to give its messenger boys one-half of each day for the study of telegraphy. When proficient they are to be provided with positions, with a considerable increase of salary. Much care is to be taken in the selection of the messenger boys, who will henceforth be considered as apprentice telegraph operators rather than as errand boys.

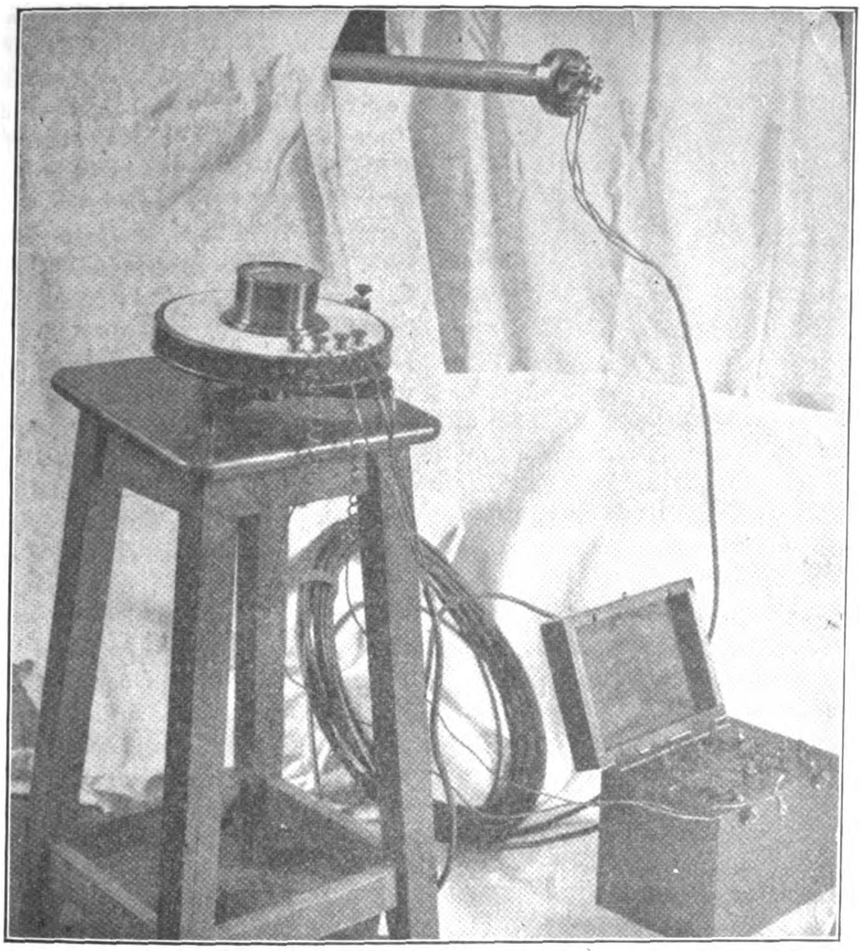
◆

According to the statistical tables relating to German public electricity supply works, compiled annually by the "Elektrotechnische Zeitschrift," the generation of electric current made considerable progress in Germany, says the "Electrician," London, between April, 1903, and April, 1904, the date to which the information in the present tables refers. On April 1, 1904, there were 51 generating stations with a capacity of 2,000 kw. or over. These 51 stations were distributed over 33 towns and their aggregate capacity amounted to 290,700 kw. The largest stations are three of those supplying Berlin: Oberspree, 13,600 kw.; Moabit, 10,640 kw., and Spandauerstrasse, 5,900 kw. Of the 1,028 stations which are enumerated in the tables, 843 supplied continuous current only, and of these 843 stations 803 were equipped with accumulators. It is interesting to note that the capacity of the storage batteries installed amounted on the average to nearly 40 per cent. of that of the generating plant. The 40 continuous current stations without accumulators were mostly small ones. Besides these continuous current stations there were about 80 stations which generated both continuous current and alternating current (mostly three-phase current), and finally there were more than 100 alternating current stations, of which 63 supplied three-phase current only. The sum total of the capacities (including the accumulator capacities) of all the German electricity stations on April 1, 1904, was 531,000 kw.

ELECTRIC PYROMETERS.

BY EMILE GUARINI.

The Siemens electric pyrometer is a platinum wire resistance thermometer, in which the platinum wire is wound upon a refractory cylinder, placed at the extremity of a closed iron tube, and protected by a platinum shield.



Direct Reading Pyrometer.

In this instrument a differential galvanometer and a series of resistance coils are used for measuring the resistance of the platinum coil for the purpose of determining the temperature, which is calculated from reference tables in accordance with the ohmic resistance noted. There are two specific applications of this method, the one stated above and the other in which the temperatures are read off direct by the use of a small d'Arsonval galvanometer in combination with a Wheatstone bridge and a circular dial provided with a sliding contact for manipulating the resistances.

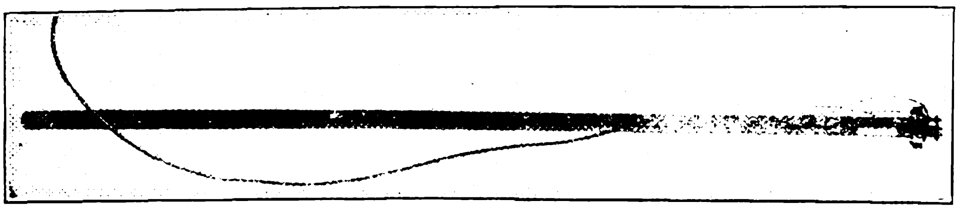
In the first method the galvanometer is set at zero and the extremity of the pyrometer is placed in the furnace whose temperature is to be determined—the upper portion of the tube being protected by fire-clay or an iron shield. The connections are made by means of special cable. When the tube has acquired the furnace temperature an electric button is pressed by which current from a source of electricity flows through two circuits, one of which comprises a coil of the galvanometer and the coil of the pyrometer, and the other part of the divided circuit comprises the other galvanometer coil and the resistance box.

If the resistance of the pyrometer coil does not equal that of the resistance box circuit, the galvanometer needle is deviated, and resistances are then plugged in until the needle has returned to its former zero position, whereby the resistance of the pyrometer coil is determined in ohms. The length of the wires connecting the galvanometer and the pyrometer have no affect upon the results obtained as these wires are of equal resistance, since their resistance varies in accordance with the variations of temperature, and thus mutually counteract each other. It then only remains to consult a table which gives the thermometric degrees for each tenth of an ohm of the observed ohmic resistance of the pyrometer.

It sometimes happens that the pyrometer coil will show an increased resistance after having been subjected to high temperatures for considerable lengths of time, which is probably caused by a slight reduction in the diameter of a wire, probably due to frequent changes in temperature, for which reason this coil should be tested from time to time at fourteen degrees Centigrade. Should the normal resistance of ten ohms have been increased for example by R ohms, all results obtained at higher temperatures should be multiplied by $\frac{10}{R}$ and the temperature determined by reference to the table in accordance with the resistance thus found. This correction is based on the observed fact that the amount of increase of the resistance in the coil, in relation to the temperature, does not change when the diameter of the wire is reduced.

The direct reading pyrometer comprises a Wheatstone bridge in which one branch has an adjustable resistance made up of a solenoid attached around the outer edge of a circular dial, which is divided into thermometric degrees, and which has at the center a small d'Arsonval galvanometer that is not affected by exterior magnetic fields; an indicating sliding contact is used for adjusting the resistance of the variable branch circuit of the bridge, and for indicating the temperature of the coil on the disk when an equilibrium has been obtained. The contact pieces are so combined and adjusted to the stem of the sliding contact, that it only suffices to press a button to place the battery in circuit with the galvanometer and the pyrometer. The whole apparatus is mounted on a tripod.

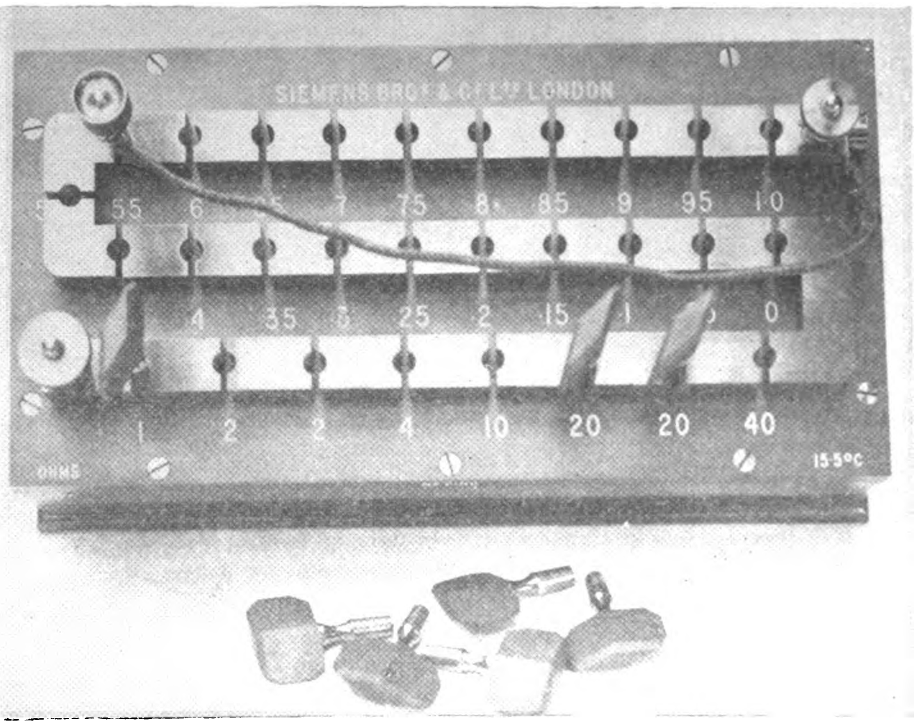
The pyrometer is connected to the apparatus by a three wire cable attached to the terminals, X X_1 and Z, the current source being connected to the terminals, C Z. In taking measurements, the sliding contact is moved around the graduated disk, and the contact lever is frequently pressed, and these operations are continued until a point is reached in which no deviation of the galvanometer needle is noted on pressing the key. The index



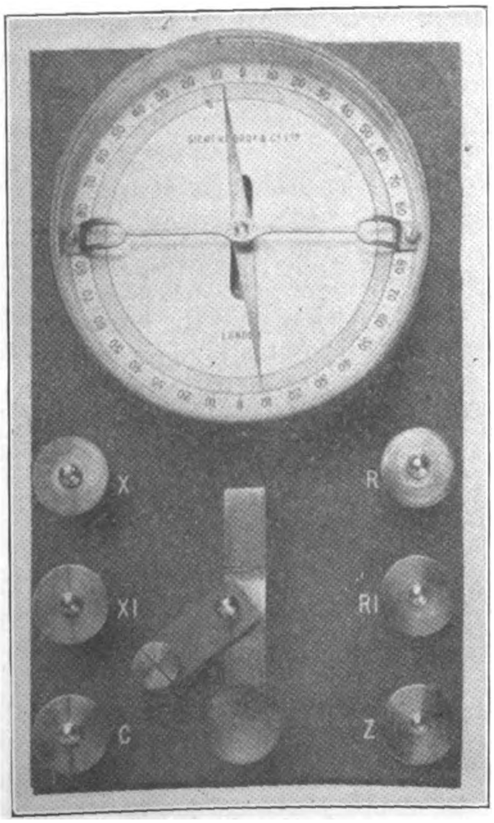
Ordinary Form of Electric Pyrometer.

under the sliding contact indicator will then give a direct reading of the temperature of the pyrometer coil.

This last form, although quite recently developed, is fully as sensitive as the first one mentioned, but it is preferable in that it obviates the inconveniences and the risks of errors due to the use of conversion tables; furthermore, there is only one part of the apparatus to be adjusted, and in contradistinction from the first method, exterior magnetic influences, due to the proximity of dynamos or strong electric currents are not to be feared.



Resistance Coils for the Electric Pyrometer.



Differential Galvanometer With Resistances for use with Pyrometer.

Whatever form of apparatus is selected, the pyrometer is found to be very precise, the measurements agreeing closely to 1 per cent. when compared with those of an air thermometer. It is quite as simple in practical use as its operation indicates, as it may be placed in the hands of an average intelligent workman.

It will be found adapted to the requirements of works where it is necessary from time to time to control the temperatures of furnaces, retorts, etc., especially where the processes of manufacture require the maintenance of a definite temperature during certain operations. Thus the apparatus will unquestionably be of great service, and it has already been adopted by the principal steel works of Europe, and by Government inspectors for determining the temperature of furnaces, during the manufacture of heavy steel pieces and armored plate.

THE LAST NEW GLOW LAMP.*

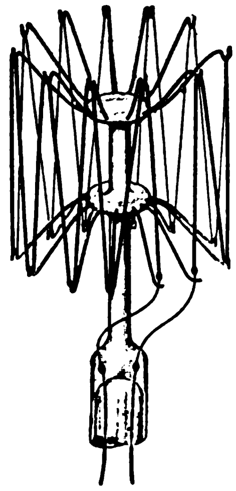
It is credited to electric lighting, even by its worst enemies, that it has made the gas people wake up. The gas lamp has been much improved and as the process has gone on there has been evidence of a reaction on the newer light. It will be remembered that in the beginning of electric lighting all the efforts of electric inventors were concentrated on the problem of producing a decent lamp. Then came a time when the carbon glow lamp was accepted as practically perfection, and the efforts of engineers were devoted to the cheapening of the production and distribution of electrical energy. Once again the pendulum has swung back, and the market is full of new lamps, and the tale of new lamps. The last example comes from Germany and threatens to be a formidable competitor of those established or seeking establishment. The Siemens & Halske Company has been for a long time engaged in an endeavor to improve the electric light at a place where there is the greatest room for improvement, viz., the hopelessly inefficient glow lamp; but the matter has been kept very quiet; indeed, the first publication was made at a meeting of the Berlin Elektrotechnischer Verein, on the 17th ult, when two papers were read by Mr. O. Feuerlein and Dr. von Bolton. The papers, and the communication of Mr. W. von Siemens, are reprinted in the "Elektrotechnische Zeitschrift" of January 26, with illustrations of the lamp and filament. There is, therefore, no longer any secrecy about the matter, and indeed one may expect to find the lamps upon the market almost immediately.

The new lamp has a metallic filament, and in fact appears to constitute a solution of a problem to which Mr. Edison originally set himself without result. Undeterred by his failures the Siemens & Halske Company some very considerable time ago set Dr. von Bolton to work on the task of finding a substance capable of being drawn into a filament, and having a melting point so high that it would give a white light before failing. What Dr. von Bolton has done is to ransack the unused elements, and it seems that he has found what is wanted in tantalum. All that is known by most people of the properties of the so-called rare elements is the descriptions of them at the end of the chemistry books. These are mostly wrong for the simple reason that the things have been prepared once or twice by men who were not metallurgists, under circumstances of considerable difficulty, and without hope of any commercial gain which would justify the expenditure of time and money in purification. Of the two standard ways of getting anything which resists ordinary methods of reduction, the electric furnace invariably involves pollution with carbon. Electrolysis of the fused salt belongs rather to an element of a low melting point, and everyone knows the difficulty of getting a pure deposit. In fact, to draw any conclusions from the descriptions of the unused metals that appear in the books is very much the same as if one were to argue on the electrical possibilities of Fe from a small specimen of cast-iron. Dr. von Bolton, in the course of his researches, tried vanadium, and found its melting point (as indeed he should have had fair warning) was much too low. The obvious course was then followed of trying the remaining elements of the same class—first niobium and then tantalum. The tantalum he has obtained is an entirely different substance to the tantalum of the books.

---

*From the "Electrical Times," London.

Pure metallic tantalum resists acids like platinum. It will burn in air, so that the lamp must be run in a vacuum; it absorbs hydrogen, nitrogen and carbon. Consequently, the tantalums that we have been put off with hitherto, though metallic in appearance, were really compounds or alloys. The tensile strength of pure tantalum is 25 per cent. better than steel. It can be drawn into wire, and it has the property which is so valuable in soft iron, viz., that it becomes malleable long before it actually melts.



Shape of Tantalum Filament.

Its electrical properties are even more convenient; the resistance of a meter wire of one square millimeter cross section is .16 ohms., but when run at its working temperature the resistance rises to .83 ohms (say five times as much). Metallic tantalum has, in fact, as becomes a metal, a strong positive temperature coefficient. The ordinary carbon filament is, as is well known, deficient in this respect, though not (when at the temperature of incandescence) to such an extent as to make special treatment necessary, but the negative coefficients of the Nernst and of the arc constitute an effective nuisance.

The chemical difficulties of the manufacture of tantalum, which are not very serious, being removed, the mechanical problem remained of constructing a glow lamp that should have a filament two or three feet long, so as to run at a reasonable voltage, and this part of the work was set out by Mr. Feuerlein. How the difficulty has been overcome will be seen from the illustration of the filament given herewith. The wire is looped round and round on a kind of frame. All metallic filaments are necessarily low resistance filaments, but it will be seen that, after all, there are compensations in working in metal instead of in carbon, or in a brittle paste of oxide. The type of lamp is already standardized for 110 volts 24 candles, and this lamp has a consumption of 1.6 watts per cp. The filament is 25 inches long and has a diameter of .05 millimeter. As the weight of it is 22 milligrams, a pound of tantalum will make more than 20,000 lamps. The life of the lamp is about 500 hours, and its behavior as regards over-running or under-running is very similar to that of the carbon lamp, except that it supports excess of pressure very much better. Started at 1.6 watts there is a fall off after 500 hours, till at 1,000 hours it becomes a 2½ watt lamp. It is, therefore, quite possible that it may end as the 1,000 hour lamp that we are used to. It will be seen that the consumption renders the lamp an immediate competitor of the Nernst and the small inclosed arc. Its great point is that, like the osmium lamp of Dr. Auer von Welsbach, it contains no mechanism. The physical as apart from the economic end of the lamp's life appears to come when the wire becomes mis-shapen and brittle. Repeated expansion and contraction results in a shortening of the length of the filament and a roughening. The new filament is quite tough, but old lamps should not be taken out or shaken (as with the gas mantle). Curiously enough, a broken lamp can frequently be mended by a simple process of tapping it until the loose ends touch each other, when they weld themselves together. It then, of course, goes on as an over-run lamp. A similar habit was promised for the Nernst burner, but nothing came of it, and it seems unlikely that this auto-repairing faculty will ever come into practical use. The appearance of the filament has already been illustrated; it merely remains to add that it is inclosed in a vacuum bulb in every respect similar to that of the glow lamp of commerce. The limits of the voltage and size mentioned do not seem in any degree fixed. It is possible that they may be capable of considerable extension, but at present only 100 to 120 volt 24 cp. lamps can be procured.

After the reading of the papers at Berlin some additional information was given by Mr. Wilhelm von Siemens; but, except for the opening remarks of the chairman, Dr. Micke, there seems to have been no discussion. Beyond appreciation of the labors of Dr. von Bolton and Mr. Feuerlein, the important part of Mr. Siemens' speech was a declaration that the lamp was quite ready. The development has been done without any preliminary writing in the newspapers, and not a word has been said about it until the company has not only got a lamp that will go, but is ready to go on turning them out for the market at the rate of 1,000 per day. Specimens of the present pattern have been running for a year.

There remains one point upon which the tantalum lamp is somewhat tantalizing; there is no information in the paper upon price. As regards the osmium lamp, with which one naturally compares it, when its producers have been asked whence they are going to get their osmium, they have replied in terms which, translated out of the language of politeness, amount to 'That's our business; we have got it.' At the same time, one naturally wants to know in what quantity. There is this about tantalum, that, although supposed to be a rare element, it exists in a quite sufficient quantity, even if no fresh discoveries are made, to provide the material of glow lamp filaments. That difficulty is no more likely to arise than in the case of finding sufficiency of the elements of the cerium group to make Welsbach mantles. And when manufactured in quantity there seems nothing in the process of production which should make it a matter of physical necessity that the new lamp should be excessively dear. It appears that the metal is reduced from the double fluoride of potassium and tantalum substantially after the manner to be found in the books. The impossible looking powder thus obtained when heated electrically under the air pump parts with the gases it has absorbed during the process of manufacture, and fuses into a workable metal.

REFUSE AS FUEL.

In view of the interest now being taken in both England and the United States in refuse destructors, the abstract of a report of a two days' test made in that country and recently published in the London "Electrical Review" should prove instructive.

The destructor is of the Meldrum "Simplex" type. It is provided with four furnaces, that is, there is one continuous grate, 20 feet by 15 feet, with four doors for feeding and clinkering, and four separated and closed ashpits, which are supplied with hot air under pressure. The ashpits are also fitted with steam jets by means of which the forced draught is obtained. The fires above the ashpits are independently controlled by the regulation of the air and steam jet supply. According to the report referred to, the liberated hydrogen due to the passing of steam through the incandescent fuel recombined with oxygen immediately above the bed of fuel, little or no air being admitted above the fires for secondary combustion. The refuse, therefore, is exposed to the maximum temperature attainable in the furnaces, instead of being first partly volatilized and then consumed as gas. Any gas which may be given off during the charging of the furnaces is consumed in the brick combustion chamber which is interposed between the grates and the main flues. The estimated mean temperatures on the two days were 2,364 degs. F. and 3,236 degs. F. A costly electric platinum wire resistance pyrometer was destroyed on being lowered into the end of the combustion chamber where the hot gases enter the boiler. A special arrangement is made at one end of the grates for the combustion of slaughter house offal. This is poured in, in a semi-liquid state, through a funnel, and any of the gases given off from it have to pass over the whole length of the fires of the four furnaces. During the test, however, no refuse of this nature was burnt, but only ordinary ashpit refuse.

Owing to the destruction of the platinum pyrometer and the bursting of a mercury nitrogen pyrometer used in the end flues, and owing also to the unreliability of high temperature thermometers, either of the mercurial or electric type, due to a considerable shifting of the zero point, the most reliable temperature data is that of the thermometers placed in the main flues leading to the chimney.

The refuse was carefully weighed on entering the premises; the ashes drawn from the furnaces were also weighed and analyzed; the feed water was measured by means of three tanks; and continuous gas samples were collected and analyzed at once in an Orsat apparatus. Similar samples were passed through calcium chloride and potash tubes to determine both the amount of moisture and the carbonic acid. These are important details in refuse destructor tests.

The boiler used in conjunction with the destructor is of the Lancashire type, 30 feet x 8 feet, constructed for a working pressure of 150 lb. per sq. in.

From Table I we note that on the two days of the trial the mean boiler pressure was 135.1 and 134.2 lb. per sq. in., the temperature of the feed-water 37.3 degs. and 35.3 degs. F., and the evaporation per lb. of fuel from and at 212 degs. F., including that used for the steam jets, was 1.698 and 1.877. The actual evaporation was 1.419 and 1.555 lb. per lb. The temperature of the chimney gases averaged 645 degs. F., which would allow of the addition of an economizer, by means of which, so says the report, the evaporation from and at 212 degs. F. would be brought up to fully 2 lb. per lb. of refuse.

Table II contains details of the gas analyses, which were only obtainable by making continuous tests, and with the help of the information thus obtained, it was possible to calculate the chemical composition of the fuel. The average of the second day's test is given as follows:

Nitrogen	79.888
Oxygen	5.836
Carbonic acid	14.233
Carbon monoxide	0.043

The estimated amount of carbon in the ashes on the second day was 17.69, and the mean ratio of moisture to CO_2 in the waste gases 0.5479.

The composition of the fuel as calculated from the above data is:

	First day.	Second day.
Carbon (burnt) per cent	21.33	31.58
Carbon (in ashes) per cent	4.17	5.70
Total carbon in fuel, per cent	25.50	37.28
Moisture, per cent	35.00	30.53
Mineral matter, per cent	39.18	31.50
Total refuse, per cent	100.00	100.00
Steam used in jets, per cent	16.22	18.7

The estimated calorific value of the fuel is as follows:

	First day.	Second day.
Calorific value of total fuel B. T. U.	3,473	5,411
Calorific value of total fuel evap. units	3.595	5.601
Calorific, less unburnt carbon, B. T. U.	2,867	4,583

A balance sheet of the heat expenditure has been made out from the data in the tables, which shows that the heat utilized in the production of steam, exclusive of the blowers, amounted to 36 per cent., which is considered a high duty in view of the fact that the carbon and heat in the ashes accounted for a loss of 20 per cent. The heat carried up the chimney amounts on the average to 19.3 per cent., which would have been lower if the refuse had contained less moisture.

In addition to the report the makers sent diagrams of the temperatures in the down-take recorded by a Callender's electric recording pyrometer, from which we note that the lowest temperature recorded is 350 degs. F., which occurred during the cleaning out of the combustion chamber. During ordinary working, the lowest temperatures are, of course, obtained during clinkering, and this appears to average out to about 800 degs. F., the highest temperature shown on the chart being 1,350 degs. F.

We might call attention to the fact that the above tests were of approximately 8 and 9 hours' duration respectively, and we gather that no economizer was used. It would be interesting to compare the evaporation obtained during longer periods. Quoting from a table previously published, we find that during 473½ hours' working continuously, except week ends, the average evaporation was 1.85 lbs. per lb., and we understand that an economizer was then used. Quoting from the same table we see that in an 8 hours' test the average evaporation, with an economizer, was 1.96 lbs. per lb., which is very close to the 2 lbs. referred to in the report as being possible.

ELECTRICITY LEAFLETS.

BY NEWTON HARRISON, E. E.

ELECTRIC LIGHTING.

Advantages of the Three-Wire System.—The three-wire system has its advantages, which are found in the saving of copper and the increased flexibility of the system through the use of a higher pressure for motors. Between the middle or neutral wire and the outer leg on either side may be found a pressure of about 115 volts. Between the two outer wires double this pressure or 230 volts is on tap for motor service. Take the case of 50 lamps taking ½ ampere apiece, fed respectively by a two and a three-wire system for purposes of comparison. On this basis 50 lamps require 25 amperes, and a two-wire system would have to supply a wire of sufficient cross-section in circular mils, to carry this current with the small loss in pressure expected in this instance. The formula for this size of wire is given as follows:

$$\text{Circular mils} = \frac{\text{number of feet of wire} \times \text{amperes} \times 12}{\text{volts drop}}$$

In the above case the circuit is 100 feet in length and a drop of 2 volts is allowed in the wire, then the calculation will give

$$\text{Cir. mils} = \frac{200 \text{ feet} \times 25 \times 12}{2} = 30{,}000.$$

The 100-foot run would mean 200 feet of wire and the 30,000 circular mils represent the square of the diameter of the wire in mils or thousandths of an inch. For instance, a wire of 100 mils diameter is 100 one-thousandths of an inch in diameter or one tenth of an inch. This wire will have 100 × 100 or 10,000 circular mils cross-section; but the wire tables give both the diameter of a wire in mils and its cross-section in circular mils with the size corresponding. The wire table most in vogue is the Brown & Sharp or B. & S. gauge.

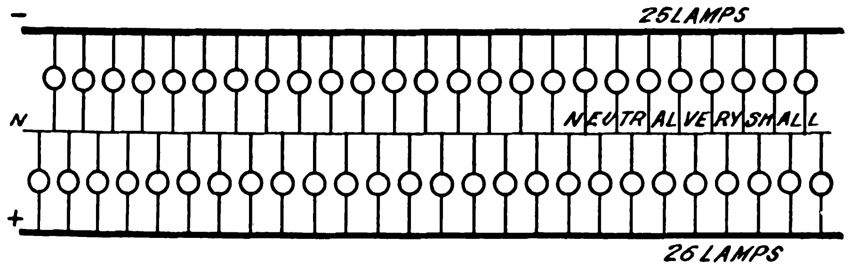
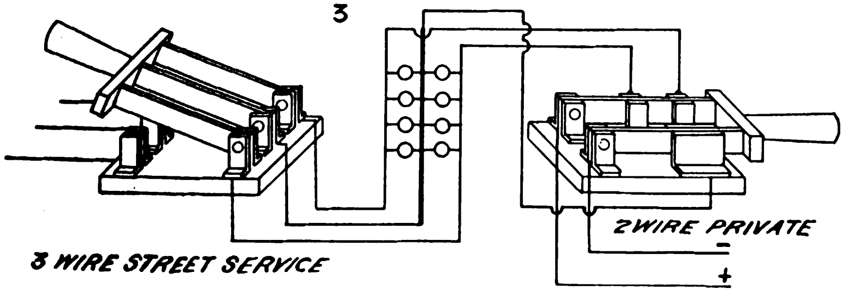
2

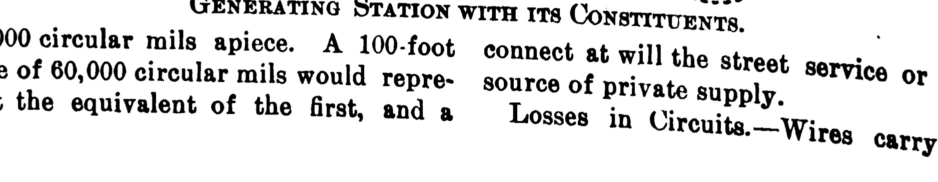


3



1—Balanced system. 2—Unbalanced system, neutral wire carries current of one lamp. 3—Combination two and three-wire system.

If the two-wire system calls for a wire of 30,000 circular mils for 50 lamps taking ½ ampere apiece with a 100 foot run and a 2 volt drop, calculation will show a smaller wire for a three-wire system of lighting with just as many lamps. In a three-wire system the lighting must be *balanced*, that is to say, as many lamps must be placed on one side of the neutral wire as the other. This will mean 25 lamps on each side of the neutral wire, which will represent 25 groups of two lamps apiece. The two lamp groups are connected across from the + to the neutral wire and from the neutral wire to the − wire. But examination will show that the 230 volts will send ½ ampere through every two lamps in series. The neutral wire in this case, when the circuit is perfectly balanced, performs no service. If there were 25 lamps on one side of the neutral wire and 26 on the other, then it would carry the current of one lamp, namely, ½ ampere. A neutral wire, in a three-wire system, therefore, carries only *the difference* in current between one side of the neutral wire and the other. Consequently, if the circuit is balanced it carries no current at all. This is the case with 50 lamps burning on the three-wire system. Only 12½ amperes are required at 230 volts pressure, which, with the same length of run, 100 feet, and the same drop, 2 volts, according to the formula calls for the following number of circular mils: $200 \times 12.5 \times 12 \div 2 = 15{,}000$. In interior house wiring, for *only* the three-wire system, three wires of this size would be used. This means in comparison, that the two-wire system would require two 100-foot wires of 30,000 circular mils apiece, and the three-wire system three 100-foot wires of 15,000 circular mils apiece. A 100-foot wire of 60,000 circular mils would represent the equivalent of the first, and a 100-foot wire of 45,000 circular mils the equivalent of the second case.



AIR COOLED STEP UP STATIC TRANSFORMER
ROTARY CONVERTER PRODUCING A.C.
D.C. GENERATOR
HIGH TENSION A.C. CONDUCTOR
ENGINE

GENERATING STATION WITH ITS CONSTITUENTS.

The saving would be the difference between 60,000 and 45,000 or 15,000 circular mils, which is 25 per cent. If the neutral wire, as is the case in the system employed in the conduits laid in the city's streets, is not as large as the outer legs, and it is easy to see that it need not be, the saving in copper is much greater. Because here, the neutral wire carrying only the difference in balance between one side of the circuit and the other, can be comparatively very small if the lighting company enforces its demand, before supplying current, for balanced circuits. The wiring contractor must see that such a balance exists in planning out the circuits, otherwise the use of the current is refused. In spite of every precaution, a certain small difference in balance in the aggregate must be taken up by the neutral wire through consumers turning lights on and off, which makes a perfect balance all of the time an impossibility, in spite of the wiring and the actual balance of the lighting circuits.

Combination Two and Three-Wire Circuits.—In private houses and public buildings where electric light plants are installed it may become necessary through a break-down of the plant to throw in the street service. A difficulty here presents itself unless the wiring conforms to the system in the street. If it is a simple alternating current system it may be thrown on with impunity provided it is of the same pressure as the lamps require. If it is a direct current three-wire system, the Edison system in fact, the wiring of the building must be composite, that is, suited to both a two-wire and three-wire system of lighting. All of this is easily accomplished if the building has been wired according to the three-wire system, only the neutral wire must be of *twice* the cross-section of the two outer legs. It can then be used for either purpose without any change whatsoever. A large double throw switch is necessary to connect at will the street service or the source of private supply.

Losses in Circuits.—Wires carrying

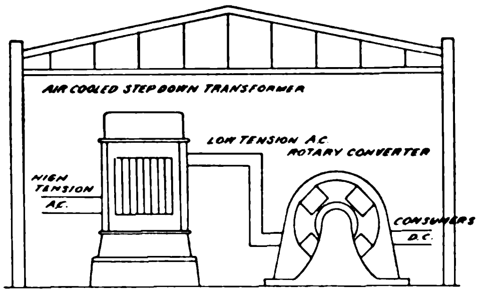
electricity from point to point dissipate energy to an extent dependent upon the current they carry and their resistance. This waste of power appears in the form of heat. An incandescent lamp is a good illustration of this when in use. The resistance of its carbon filament is sufficiently great with the current passing through to raise it to incandescence. In the same manner although not to the same extent a conductor is heated by the energy it contains and a certain percentage of power disappears. This can be regarded in two ways: first, as caused by lost volts or drop, and second, as due to the energy wasted as heat. To calculate the first or volts lost this formula is employed:

Volts lost = amperes in wire × resistance of wire.

If the lost volts are multiplied by the amperes, the watts wasted in the wire are obtained. On the other hand, the power which generates heat can be calculated by the formula: Watts wasted in heat = amperes × amperes × resistance of wire. These two results will be the same, as shown by the following example: Take a wire of 10 ohms resistance carrying 2 amperes, the volts lost $= 2 \times 10 = 20$ and the watts wasted $= 2 \times 20 = 40$. If the watts wasted in heat are calculated by the other method the result is: Watts wasted $= 2 \times 2 \times 10 = 40$, or the same figures in both cases. One is obtained by the product of the drop in volts by the amperes, the other by the square of the amperes by the resistance. As there are 746 watts to a horse power, the percentage of a horse power wasted in the conductor can be readily obtained.

Where many lines are in use carrying power the loss is considerable, particularly when the current is heavy. The loss increases rapidly as the current increases and as it decreases diminishes. In the case just stated, if the amperes are raised from 2 to 4 the watts wasted increase from $2 \times 2 \times 10$ to $4 \times 4 \times 10$, which equal respectively 40 and 160 watts, a difference of 4 to 1 with only twice the current. Therefore if the resistance of a line remains the same and the current is doubled, tripled or quadrupled the waste of power is increased 4, 9 and 16 times respectively. Reducing the current in conductors transmitting electricity for light and power and increasing the pressure is a logical process. To accomplish this successfully in electric light practice has been one of the most difficult problems. It has been solved of a flexible system of transformation by means of which a direct current is changed into an alternating current of high potential, and a high potential alternating current into a direct current of low potential.

Method of Transformation.—A central station in the heart of a great city represents two ideas in electric lighting. It may generate electricity for both *transmission* and *distribution*. In other words, it is equipped with apparatus by means of which it can distribute electricity at low potential within a considerable radius of itself. It can also transmit energy at a high pressure to certain points relatively far removed, and there have that energy undergo a process of transformation to low pressure preparatory to its distribution. Essentially, the function of a central station is the generation and distribution of electricity for electric light and power service, but it must operate as well as a power transmission plant in order to distribute its energy with economy over an increasing radius. To deliver heavy amounts of energy one or more miles away with little loss and thus create a new center of distribution is accomplished as follows:



SUB-STATION WITH ITS CONSTITUENTS.

The central station is supplied with two classes of machinery; one, which generates the current at low pressure, continuous and ready for distribution; the other which transforms it to a high pressure alternating current for transmission, prior to ultimate distribution at a distance. The low pressure direct current generators supply an area in the immediate neighborhood by means of the three-wire system. They also supply energy to rotary transformers or converters, which are machines representing a combination of a motor and dynamo in one. On one side the machine receives a low pressure direct current which operates it as a motor; it gives out an alternating two or three-phase current at a somewhat higher pressure. This is obtained by means of two armature windings, one of which is for continuous and the other for alternating current. A commutator is connected on one side of the machine to the direct current winding and collector rings on the other side to the alternating current winding. Although a direct current will rotate the armature and thus generate on the other side of the machine a two or three-phase alternating current, if a two or three-phase alternating current, as the machine may require, is sent in at the collector rings the resulting rotation will develop a direct current at the commutator. Thus a rotary converter is capable of taking in a direct current and giving out an alternating current, and, conversely, it can take in an alternating current and give out a direct current. It is thus, as a rotary converter, truly convertible, and for this reason invaluable in the transmission of power.

The alternating current given out by the rotary converter is practically the full equivalent of the energy sent in in the shape of a direct current. This alternating current is received by a transformer in which, though entering at a few hundred volts it leaves at a pressure of many thousands, but otherwise still unchanged in character. In this manner, a current of high pressure and alternating is sent over transmission lines either underground in conduits or overhead to reinforce distant stations or to create at new points what are called sub-stations.

The Sub-station.—The current, which can be considered, for purposes of illustration, a 5,000-volt three-phase, is now received at the sub-station to undergo a new process of transformation. To outline the previous process in the station itself, it is only necessary to consider a 115 or a 230-volt direct current entering the rotary converter and issuing as a 300 or 500-volt three-phase alternating current. Sending this current into a transformer at this pressure, from which it emerges at 5,000 volts and goes over the line, brings these operations to a point where the substation becomes of interest. In this edifice are to be found stationary or static transformers and rotary converters. The power is received in the transformers at 5,000 volts and issues at 300 or 500 volts. It is then directed into the rotary transformer from which it issues as a continuous current of 115 volts and feeds into the three-wire system in common with the generators of the central station.

Why a Two or Three-phase Current is Necessary.—A two or three-phase alternating current is particularly adapted to power plants because of this qualification—it can be used in motors which thereby become *self starting*. A single-phase alternating current has been applied to some extent to the same purpose by means of special appliances, and the ordinary series motor will operate with a single-phase current, but the type of motor now in use extensively for power plants and power transmission is of the character known as "the rotary field motor." In other words, a two or three-phase alternating current can be sent into a motor so designed that it creates within it the equivalent of a rotary field. A wave of magnetism sweeps around and carries with it the armature which it affects by induction. This armature is of simple construction; an iron core, laminated, conductors closed upon themselves and a multipolar field. The current enters the field and produces the rotating wave of magnetization, the armature follows a little behind in speed. No commutator is needed and therefore a great advantage is at once gained. The rotary field motor is the result of the work of Tesla, Ferraris and Dobrowolsky and was the only means of making power transmission and distribution a success. If appropriate conductors are placed on the armature of a two or three-phase motor and connected to a commutator with brushes, etc., any transformation required can be obtained within the limits of insulation. Street railway as well as electric light and power plants can thus be operated by power obtained from a distant source. This power, sent at a high pressure alternating, can be received at various sub-stations along the line of the trolley or third-rail system. It is transformed by means of *step-down* transformers and sent into rotaries, from which it issues as a direct current at the standard pressure. The transformers which raise the pressure are called *step-up* transformers and those which lower it *step-down*. Thus the conjunction of rotaries and static transformers provide an ideally flexible and highly economical system for electric transmission and distribution.

◆

THE AMERICAN DIESEL ENGINE.*

BY NORMAN M'CARTY.

Many of your members will remember certain papers published some years ago in regard to the merits of a new invention in prime movers called the Diesel motor.

The claims set forth as to the economy of this device were so large and far-reaching that most practical men received them with a shrug of the shoulders. They were, nevertheless, not only true, but somewhat understated. From the small Diesel motor of 20 hp., which gave these remarkable results, has grown, by a natural process of evolution, the American Diesel engine of to-day, at present built in sizes from 75 B.H.P. to 1,000 B.H.P.

A short explanation of the working of this engine may be permissible as many, no doubt, have forgotten the former explanation, while to others the matter may be entirely new.

The Diesel engine is essentially an oil engine and not a gas engine. Gas engines and previous oil engines which acted on the gas engine principle have all in common the explosion of a charge. This charge is a mixture of a given quantity of gas or of a given quantity of oil vaporized so as to act as a gas during the process, combined with a quantity of air varying from seven to eleven times the volume of the gas or vapor. It was well known that some previous compression would add to the economic results of the explosive action. But in all cases the power was obtained by an explosion, which, from the moment of ignition, was beyond control of the operator, or of the governing mechanism of the engine. This fact limited the efficiency of all governing devices which could be applied, and troubles with the ignitor caused other irregularities, so that even where local conditions made the gas engine (or vaporized oil engine) the worthy competitor of the steam engine, uncertainties of its operation threw doubt on the wisdom of the substitution.

Furthermore, a cheap gas, necessitating the installation of a large and cumbersome producer plant, was the only escape from such costly fuels as gasoline or kerosene.

The Diesel engine made the use of the cheapest liquid fuel, such as crude oil, fuel oil and distillates, possible. To these recent experimental developments promise to add the waste product from gas works known as light water gas tar.

The Diesel engine works on an entirely new principle. First of all it dispenses with the so-called charge or mixture, which in all explosive engines must vary only between the limits of one gas to seven air, and one gas to eleven air. Its cycle is the same as the gas engine, the well-known Otto cycle. There its similarity with the gas engine ends absolutely; in everything else it follows the precedent of the steam engine.

Its first stroke is a suction stroke, drawing in a cylinder full of pure, clean air; on the second stroke it compresses this to a tension and consequent temperature sufficient to ignite any fuel which may be injected into it; at the beginning of the third stroke a small quantity of fuel oil is injected into this red-hot air as a spray by a jet of highly compressed air, and thus, in a completely atomized state, the fuel meets and mixes with the hot compressed air in the cylinder, burning completely, and during a period of time exactly regulated by the governing mechanism of the engine, generally through one-tenth part of the stroke (when engine is operating at its rated capacity), subsequent to which the stroke is finished by the expansion of the burnt products or gases; the fourth stroke discharges these products of combustion and leaves the cylinder empty and ready for another suction stroke.

It is evident that the work expended in compressing the cylinder volume of pure air is given off again to the shaft of the engine during the combustion or motor stroke, so that the loss is simply the fractional loss during the compression stroke.

This simple process, absolutely new and original with Diesel, has enabled him to accomplish with one-half pint of common crude or fuel oil as much as the explosive engine does with a full pint of the much more expensive gasoline.

A recent comparison of results extending over a period of regular daily service of six months has shown the consequent economy of a Diesel engine over a first-class gasoline engine, which it displaced, of 600 per cent.

The modest statement set forth some years ago by the promoters of the Diesel engine, and covered by absolute and binding guarantees, are that 100 B.H.P. hours measured in the crank shaft of the engine will require not exceeding eight gallons of crude oil or fuel oil when the engine is running at or near its greatest capacity, nor more than nine and one-half gallons when it is running at or near half load.

The regulation in the Diesel engine is not dependent on hit or miss, but can be followed up or down the scale as closely as in a steam engine. In the latter it is a question of cutting off more or less from a pretty large volume of steam at each stroke; in the Diesel engine it is the finer one of cutting off a more or less minute quantity of oil from the small volume delivered by the fuel pump at each stroke. It is accomplished by direct action of the governor on the suction valve of the fuel pump, which is held open during a greater or less portion of the pressure stroke, and thus the pump delivers the exact quantity of oil required during each motor stroke of the engine. While the mechanism is necessarily smaller and more delicate than in the steam engine, it also requires less power and its effect is more immediate.

In a compound steam engine the volume of steam left in the high pressure cylinder at the point of cut-off must be used in the next stroke of the low pressure cylinder, whether at the time more or less would be the proper quantity for that stroke. In the Diesel engine the regulation acts on each cylinder just at the time and in the exact quantity then required.

---

* Paper read at the 13th annual convention of the Northwestern Electrical Association, held at Milwaukee, Wis., Jan. 18-20, 1905.

There remains only the drawback common to all four-cycle engines, that there is but one motor stroke for each two revolutions. For electric light work, triple cylinder engines and heavier fly-wheels successfully overcome this, while for electric railway work resort is had to still larger fly-wheels and four or six cylinders by coupling on engines at each end of the same dynamo shaft.

As for the accessibility, reliability and durability of the engine, three years of experimental work have placed these fully on a par with the best steam engine practice, and since then, two years, and in some cases nearly three years, of continuous service by a number of Diesel engines of the new American type gives sufficient examples of the success in this work.

An installation of 50 engines, aggregating 6,000 B.H.P., and representing 25 separate and distinct plants, in service from 6 months to 5 years, has so demonstrated the fuel economy that the American Diesel Engine Company offer the following formula to any user of power, by which he may determine for himself the exact cost of fuel from his operating conditions, under the supervision of his own attendants and for any length of time he may desire, the result of which they are ready to guarantee, assuming that the plant has averaged one-half load for the time under consideration:

FOR ELECTRICAL TRANSMISSION.

$$\frac{A \times 365 \times B}{8} = \text{cost of fuel per year.}$$

FOR MECHANICAL TRANSMISSION.

$$\frac{A \times 365 \times B}{10.75} = \text{cost of fuel per year.}$$

In which case

A = number of kw. hours, or B.H.P. hours per day.

B = cost of oil fuel in cents per gallon.

For example, assuming that an electrical installation delivers 1,000 kw. hours per day, with oil fuel at 3 cents per gallon, we have

$$\frac{1{,}000 \times 365 \times \$.03}{8} = \$1{,}368.75 \text{ as total}$$

cost of fuel per year of 365 days. But as the Diesel plant requires no boilers and eliminates the extra expenses of the fire room it should be credited with this necessary charge against a steam plant, so that assuming the charge for water, labor and depreciation of boilers for a steam plant of this size at $2.50 per day, or $912.50 per year, the cost of fuel for the Diesel would be only $1,368.75 — $912.50, or $456.25 per year in excess of fire-room charges (exclusive of coal used) necessary for steam, and the total coal bills for a steam plant must be kept within this amount if it would meet the operating expenses of a Diesel plant. But an average steam plant delivering 365,000 kw. hours per year would probably require under actual operating conditions 1,100 tons of coal at, say $3 per ton, or $3,300, and assuming the labor and supplies in the engine room of each plant as equal, the Diesel would make a saving of $2,843.75 per year, or at least 30 per cent. of the cost of installation.

A larger plant, delivering 10,000 kw. hours per day, would cost for the Diesel $13,687.50 per year, with fuel at 3 cents per gallon.

Assuming this to be a 1,000 kw. installation, the charges in the fire-room of a steam plant (which charges we assume to cover depreciation as well as water and labor) would approximate $5,000 per year, leaving the cost for Diesel fuel at $8,687.50 in excess of fire-room charges for a similar size steam plant, and which must cover coal bills, as suggested above, to meet the Diesel economy.

Three million, six hundred and fifty thousand kw. hours for a steam plant would represent at least 7,300 tons of coal, or, at $3 per ton, $21,900, a saving for the Diesel of $13,212.50, equal to 60 per cent. of the coal bill, or approximately 20 per cent. of the cost of installation. The coal consumption being based on 4 pounds per kw. hour, or 2½ pounds per I.H.P., will probably not be seriously disputed by any steam authority, considered as covering average working conditions.

The essential features that distinguish the Diesel engine from all other prime movers are:

1. As all oil fuels have practically the same calorific value, the cheapest is equal to the highest priced for the purpose intended.

2. The fuel consumption being controlled automatically by the governor, the consumption on variable load approaches very much nearer the theoretical requirements than when dependent on manual control, as in a steam plant.

3. The medium for compression being pure air and non-explosive, no back-firing is possible.

4. The ignition being caused by the heat of compressed air, no ignitors are necessary, and no mixtures or explosions tolerated.

5. The ignition and combustion is gradual and continuous, with a surplus amount of air to maintain complete combustion. Consequently, no carbon is deposited and no fouling of valves or cylinders possible.

ENGLISH ELECTRICAL NOTES.

(From our London Correspondent.)

ARMATURE REACTION.

Messrs. J. B. Henderson, D.Sc., and J. S. Nicholson B.Sc., have lately made a comparison between the theoretical and experimental armature reaction of a 30 kw. three-phase alternator in the James Watt Laboratories of the University of Glasgow. The machine has rotating field poles and gave 50 periods per second at 750 revolutions per minute; the normal E.M.F. is 200 volts and the current per phase winding is 87 amperes. An account of their investigation and the method of experimenting employed, together with the results obtained, were given before the Glasgow section of the Institution of Electrical Engineers by the two gentlemen named. They find that the theoretical load curves of the three-phase generator which were calculated in the paper by a method like Blondel's, employing a Fourier analysis of the armature M.M.F.'s, do not agree with the experimental load curves within the limits of the experimental errors, but deviate from them in certain well-defined respects. The limits of experimental error are a small fraction of the maximum deviation, and the deviations themselves are so small as to be negligible in matters of design.

MAGNETIC TESTING.

During the last two years Mr. G. F. C. Searle, M. A., of the Cavendish Laboratory, Cambridge, has been making an investigation of the magnetic treatment of transformer plate and the great influence that it may exert upon the change of induction subsequently found on the reversal of a given magnetic force so as to make ballistic tests of transformer iron liable to great uncertainties. His investigation of these effects was made with the hope of finding how to obtain a definite value for the change of induction due to the reversal of a given force, and of gaining some information as to the effects produced by some selected modes of magnetic treatment upon the change of induction subsequently found on the reversal of a given force. Mr. Searle also examined the effects of the mechanical disturbances involved in the preparation of the specimen for testing, and has considered how far the results obtained with a single specimen may be taken as representative of the magnetic quality of a whole batch of sheets of transformer iron. The work is therefore more or less a critical examination of the use of the ballistic method in magnetic tests of transformer iron, and Mr. Searle himself gave a most exhaustive account of the experiments undertaken and the results obtained in a paper on "Studies in Magnetic Testing," which was read before the Institution of Electrical Engineers in London.

Cause of Vapor Explosions.

An interesting correspondence says the London "Electrical Review," has been proceeding for some time in the "Chemiker Zeitung" on the cause of the occasional explosions of vapors which have taken place at different chemical works. A very inflammable volatile liquid, carbon bisulphide more particularly, has been run through metallic pipes, or through a metallic funnel, into a metallic or non-metallic drum, replacing the air formerly in that vessel. Part of the liquid has evaporated, forming a mixture of vapor and air, which, in the total absence of fire or artificial light, has exploded, and done more or less damage. It has been so difficult to find the proper explanation for this curious phenomenon, that certain writers have suggested that the friction of the passing liquid upon the edges of the funnel or the mouth of the pipe must have generated sufficient electricity to produce a spark, which has immediately fired the explosive mixture.

A more probable, and entirely chemical, explanation of the explosions has now been put forward, which appears to meet all the requirements of the case. According to this view, when a volatile organic liquid of the kind now under consideration, which contains sulphur, either as a part of its nature, or as an impurity, is brought into contact with iron or steel, sulphide of iron is formed. In presence of air this body oxidizes, generating so much heat in the process as to raise the mixture of vapor and air above its inflaming point, when, if it takes fire in a confined situation, it produces the symptons of a gas explosion.

A New System of Train Control.

The Cutler-Hammer Manufacturing Company of Milwaukee, Wis., has recently taken out a patent on a new system of controlling electrically-propelled trains, operating on the multiple unit plan. The principal feature of the invention lies in the fact that both the direction and speed of the driving motors of the entire train are controlled by means of two wires running the entire length of the train, and by use of a controller of about the same size as a standard field regulator for a 3 kw. generator. The two wires constituting the train line are attached at each end of the car to automatic couplings, which enable the cars to be shifted either end to, thus requiring no attention in coupling up so far as the electrical equipment is concerned. The maximum current carried by the two-wire train line is the output of a 3 kw. 110-volt generator when used in connection with six cars equipped with four motors on each car, capable of developing 300 hp. per car.

Electrical Supplies Wanted.

The Bureau of Supplies and Accounts of the Navy Department will open bids on March 7 for furnishing the New York, Boston and other navy yards with the following: Schedule 88, Arc and incandescent lamps; induction coil; wattmeters, wire, conduit and fittings, electrical supplies; schedule 89, motors, dry battery cells, copper conductor; schedule 91, electrical supplies; schedule 92, motors. Blank proposals will be furnished on application to the navy pay office in New York or to the bureau at Washington. Applications should designate the schedules desired by number.

Plant for Electrical Exchange Building.

A contract has been let for equipping the Electrical Exchange Building, 136 Liberty street, New York City, with a 75 hp. and one 40 hp. Buffalo horizontal center crank engine for direct connection to generators of 50 kw. and 25 kw. capacity respectively. The three-wire system will be made use of and it is expected the plant will be in working order about May 1.

Society of Chemical Industry.

The next meeting of the New York Section will be held at the Chemists' Club, 108 West 55th street, on Friday evening, February 24. The following papers will be read: "Tetrachloride of Carbon and its Use as a Solvent in the Differentiation of Bitumen," by C. Richardson and C. N. Forest; "History of Artificial Musk," by H. Schweitzer, and "Tannin and Tanning Materials in Relation to Tariff Classification," by Wilton G. Berry.

The Howard Company Moves.

The Howard Miniature Lamp Company, heretofore located at 221 Canal street, New York City, has removed to more commodius quarters at 58-60 Reade street. Here this well known concern will in the future as it has in the past turn out high grade incandescent lamps.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED FEB. 14, 1905.

Electric Railways and Appliances.

782,405. Trolley. John Martland, Detroit, Mich. Filed Jan. 2, 1903. Renewed Nov 25, 1904.

782,455. Car-Signal System. William Lintern, West Park, O. Filed Nov. 28, 1904.

782,589. Trolley. Benjamin Williams, Columbus, O., assignor of one-half to W. F. Volk, same place. Filed June 17, 1904.

782,652. Insulated Rail-Joint. George L. Hall, New York City, assignor to the Continuous Rail Joint Company of America, Newark, N. J. Filed Jan. 9, 1904.

782,751. Automatic Electric Railway-Signal. William S. Jackson, Hoboken, N. J., assignor of one-half to David Young, Newark, N. J. Filed Jan. 9, 1904.

782,756. Trolley Guard. Edward R. North, Webster Groves, Mo. Filed May 6, 1904.

782,786. Trolley-Pole Controller. Joseph P. Magney, Los Angeles, Cal., assignor to the Magney Manufacturing Company, same place. Filed July 11, 1904.

782,796. Trolley-Switch. Alexander Palmros, Columbus, O., assignor, by mesne assignments, to Joseph A. Jeffrey same place. Original application filed Sept. 24, 1897. Divided and this application filed June 6, 1901. Renewed June 13, 1903.

Electric Lights and Appliances

782,749. Incandescent Electric Lamp. John H. Guest, Brooklyn, N. Y. Filed May 14, 1904.

Electrical Machinery and Apparatus.

782,340. Means for Regulation of Dynamo-Electric Machines. Albert S. Hubbard Greenwich, Conn. Filed Feb. 20, 1902.

782,386. Fraud-Detector for Electric Meters. Wallace W. Fuller, Charleston, S. C. Filed May 20, 1904.

782,593. Mechanism for Operating Electric Motors and Controlling the Speed of Devices Actuated Thereby. Otto C. Britsch, Maspeth N. Y., assignor to David Wald, New York City. Filed May 16, 1904.

782,646. Electrical Drive for Hydro-Extractors, William L. D'Olier, Philadelphia, Pa. Filed July 25, 1903

782,731. Magnetic Controlling Mechanism. Arthur C. Eastwood, Cleveland, O. Filed Aug. 27, 1904.

782 732. Controller for Electric Motors. Arthur C. Eastwood, Cleveland, O. Filed Sept. 14, 1904.

Telephones and Telephone Apparatus.

782,323. Telephone System. Daniel W. Campbell, La Crosse, Wis., assignor to the Vought-Berger Company. Filed June 21, 1904.

782,376. Four-Party-Line Telephone System. Garrison Babcock, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Manufacturing Company. Filed Nov. 14, 1903.

782,382. Telephone-Exchange System. William M. Davis, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Manufacturing Company. Filed May 20, 1903.

782,419. Intercommunicating Telephone-Switch. William H. Rose, Catonsville, Md. Filed Nov. 21, 1904.

782,562. Telephone-Register. Merritt Hitt, Los Angeles, Cal. Filed July 7, 1903.

Miscellaneous.

782,254. Telegraph-Relay. Joseph W. Larish Bridgeport, Conn., assignor to the United Press, New York City. Filed Aug. 18, 1904.

782,308. Electrolytic Apparatus. Arthur Wright, Brighton, Eng. Filed March 23, 1903.

782,311. Electric Display Apparatus. Edmund L. Zalinski, New York City. Filed Sept. 6, 1904.

782,387. Electric Time-Switch. William H. Gerhard, Austin, Tex. Filed Sept. 15, 1904.

782,391. Electric Cable. Albert P. Hanson, Charlottenburg, Germany. Filed March 19, 1904.

782,422. Receiving Apparatus. Harry Shoemaker Jersey City, N. J., assignor to the International Telegraph Construction Company, New York City. Filed Sept. 1, 1904.

782,453. Thermostat. John I. Linler, Aiken, S. C. Filed Feb. 13, 1904.

782,456. System of Electrical Distribution and Control. Edward Lyndon, New York City. Filed March 24, 1904. Renewed Jan. 16, 1905.

782,525. Electrical Water-Heater. Milton H. Shoenberg, San Francisco, Cal., assignor to the Shoenberg Electric Appliance Company, same place. Filed June 30, 1904.

82,550. Electric System. Horace Dowie, Brooklyn, N. Y. Filed April 19, 1904.

782,576. Conduit for Electric Wires. Robert W. Lyle, New York City. Filed May 2, 1903.

THE TELEPHONE WORLD.

Will Not Stand Bell Company's Charges.

A meeting was held about ten days ago in Mt. Clemens, Mich., between a committee from the Business Men's Association, consisting of Messrs. Epley, Daley and Ullrich, and General Manager Land of the Michigan State Telephone Company. The telephone representative showed the local business men a mass of figures tending to show that the company was losing money in Mt. Clemens, but made no proposition to compromise on the rates which are being complained of as excessive. The company's figures showed that for the past year it paid $30,000 for the exchange and improved it by spending $34,000. Depreciation amounted to $16,000, making its present value $48,000. The company desires to make at least 6 per cent. on its investment.

The citizens decided to establish an Independent exchange and secured about $3,000 worth of stock at the meeting.

Iowa Telephone Association.

We are informed by Charles C. Deering, secretary, that the ninth annual meeting of the Iowa Telephone Association will be held at the Chamberlain Hotel in Des Moines March 14, 15 and 16.

The meeting of the association will be held in one of the private dining-rooms on the parlor floor. Telephone manufacturers and supply men will have their exhibits on the fourth floor.

The association banquet will be held Wednesday night, March 15.

Since the union of the Wayne County and Wayne-Monroe (N. Y.) Telephone Companies under one management was effected some six weeks ago so many orders for 'phones have been received in the local telephone office and so many instruments have been installed throughout the village that now scarcely a business house and a very small percentage of residences remain unconnected with central. Patrons of the service are rejoicing at an all night and all day Sunday service. Another great advantage effected by the merger of the two lines is the unlimited free from toll service extending to all districts of the town. Palmyra remains the only one of Wayne's 15 towns in which the Wayne-Monroe telephones are not operative. The telephones recently installed in Lyons are of the new Stromberg make.

A Reading, Pa., dispatch says that farmers who are living near the telephone lines of the Bell and Pennsylvania Telephone Companies are assured of telephone service, the like of which has not been contemplated in the country. Wherever a group of farmers wish the service they will be allowed to build their local line and make connections to the main wires of the companies. This advantage will be accepted by hundreds of farmers within a radius of many miles of Reading. The cost will be very reasonable.

The Michigan Independent Telephone Association has decided to hold its convention this year in Battle Creek, February 23 and 24. The Post Tavern will be the headquarters. About 200 delegates are expected.

New Independent Company in the Field.

An Independent telephone company has been organized in Jefferson County, Tenn., with headquarters at Piedmont, and is called the Piedmont Telephone Company with the following officers: General manager, Dr. William R. West; secretary, W. M. Brooks.

The line will run from Piedmont to Knoxville, Kodak, Strawberry Plains, New Market, Jefferson City and Dandridge. The stock is sold and work has already begun. There will be a general exchange at Piedmont. The company has petitioned the board of mayor and aldermen of Jefferson for a franchise to enter that city to connect with the People's line there. The matter was referred to the ordinance committee and it is expected that the franchise will be granted.

This line will run through some of the best farms and accommodate a large number of farmers through a splendid section of country. The stock is taken by and the line is being built mostly by the farmers, and will put in communication with the business world hundreds of people who have had no telephones. Already orders have been given for about 200 'phones on the line.

The Cass County Telephone Company is being organized at Pequot, Minn., the object being to erect lines that will connect the large farming communities in the southern part of Cass County with some of the villages. Five new connections have recently been made between Hazel Dell and Poplar and more than 30 'phones are now in use. When the telephones were first put in the batteries were intended for only 25 telephones, so that it has been found necessary to put in a switch to handle the increasing business connected with this Independent line. The line will at once be extended from Motley to Pequot by way of Leader. Olaf Olson, county superintendent of schools, and W. H. Hallet are the principal promoters.

At the annual meeting of the stockholders of the Cuyahoga Telephone Company of Cleveland, O., three new directors were elected. They were H. P. McIntosh, of the Guardian Savings & Trust Company; C. W. Wason, who is interested in Cleveland traction properties, and Calvary Morris, of the Morris Coal Company, and president of the Cleveland Trust Company. They take the places of Barney Mahler, T. F. Pomeroy and J. W. Marsh. The other directors were re-elected as were the old officers. This leaves F. S. Dickson at the head of the company as its president. No change was expected, since the record of the officers was an excellent one.

Arrangements have been made to extend the farmers' telephone lines in East Lee, Tyringham, Otis, Becket and Washington, Mass. L. S. Black of Boston has been in these towns arranging for the service, which will be installed at a cost of $1.50 a month, 15 subscribers on a line. The plan is to have the farmers' lines central office in Tyringham. The company is to cover about 40 miles of pole line and will require about 1,600 poles. Connection to the trunk lines will be made at Lee and Westfield.

Complete Long Distance Lines.

The Pittsburg & Allegheny Telephone Company recently announced that the long-distance lines connecting Pittsburg with Northern Central and Western Pennsylvania and also Ohio and West Virginia, which have been in process of construction, are now completed. Direct lines to Wheeling, W. Va., and to Butler have also been completed. Additional lines to Johnstown and Uniontown, Pa., connecting with lines to Baltimore and Philadelphia, are now in process of construction.

An entirely new system of telephone service and a new scale of prices, meaning the expenditure of the proceeds of an $800,000 bond issue, will be installed by the Syracuse (N. Y.) Telephone Company in the near future, if present plans are carried out, according to statements made lately by Ernest I. White, one of the directors and attorney for the company. Mr. White said when questioned about the matter: "We are not positively certain that the improvements will be undertaken, but the prospect is that they will be."

Superintendent West, of the Southern Bell Telephone & Telegraph Company, estimated his loss from the recent storms as between $75,000 and $100,000, and Superintendent Simmons, of the Atlanta Telephone & Telegraph Company, states that the loss of his company is about $10,000.

The Greenville and Kennebec Telephone & Telegraph Company has been organized at Greenville, Me., for the purpose of locating telephone and telegraph lines in the region about the head waters of the Kennebec River, with $10,000 capital stock. The officers are: President, Charles D. Shaw, and treasurer, Henry M. Shaw, both of Greenville.

The local telephone companies of Port Jefferson and Patchogue, N. Y., lately connected their lines and now have complete communication throughout the town of Brookhaven, and expect to make connections very shortly with other local telephone companies on Long Island. The two companies now have about 300 subscribers.

Thomas Taggart, proprietor of the General Hotel, Indianapolis, Ind., announces that he will install a telephone in each of 276 rooms of his hotel.

Telephone Incorporations.

The Saginaw Valley Telephone Company, Saginaw, Mich. Capital stock, $850,000.

The Coshocton County Telephone Company, Coshocton, O. Capital stock, $30,000. Incorporators: Joseph A. Finlay, James L. Beck, J. H Elder, W. D. Kissner and S. C Kissner.

The Bloomer Home Telephone Company, Bloomer, Ill. Capital stock, $5,000.

The Prairie Hall Telephone Company, Lexington, Ill. Capital stock, $4,900. Incorporators: Gilson H. Elder, John A. Moon and George C Elder.

The Sangamon County Telephone Company, Pawnee, Ill. Capital stock, $20,000. Incorporators: H. E. Farnam, B. L. Farnam and Hattie M. Farnam.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Anaheim, Cal.—The city trustees favor voting bonds from $10,000 to $15,000 to enlarge and improve the city electric light and waterworks plants.

Arcanum, O.—The city council will vote March 6 for the construction of an electric light plant and city waterworks.

Boulder, Col.—The Boulder Electric Light & Power Company has asked the city council for a franchise for a period of 25 years.

Branchville, S. C.—This city will install an electric light and power plant. Address William Warren, mayor, or G. M. Noble, clerk.

Carlisle, Ark.—This city is to have electric lights.

Denver, Col.—The Denver Gas & Electric Company will enlarge its plant at the corner of 20th and Blake streets.

Elgin, Ill.—The Elgin Hydraulic Company has under discussion the matter of establishing an electric light and power plant.

Enid, Okla.—The erection of an ice and electric light plant is proposed by J. F. Levors of this city.

Galesburg, Ill.—A resolution was recently passed by the city council which may result in this city furnishing its own electric lights, especially for public buildings.

Hartford, Ky.—Ike C. Adair has been elected president and J. D. Cooper vice-president and general manager of the Kentucky Light & Power Company, a new corporation recently formed to install an electric light plant here.

Hope, Ind.—George S. Cook has secured a franchise to establish an electric light plant here.

Houston, Miss.—This city has voted to issue bonds to the amount of $15,500 for an electric light and waterworks plant. J. M. F. Griffin, city clerk.

Iron River, Wis.—This city and Stanbaugh people are figuring upon building a joint electric light plant.

Kirkwood, Ill.—Dr. J. F. Kyler and J. F. White have been granted an electric light franchise by the city council of Biggsville.

Madill, I. T.—A 20-year franchise has been granted to F. W. Porter of Whitehall, Wis., by the town council for an electric light plant.

Maxville, O.—This city is to have one of the finest electric light plants in this State.

Pittsburg, Kan.—The city council has granted a franchise to Morris Claggitt and others to furnish this city with electric light and the operation of a power plant.

Pontiac, Mich.—A. Jacobs of Detroit will probably erect a gas and electric light plant here in the near future.

Rifle, Col.—It is reported that an electric light plant to cost about $50,000 willbe erected here by A. L. Hackenberger of Dallas, Tex.

Roanoke, Va.—C. H. Stanley, J. C. Moir, H. J. Hartzberger and others have organized a $40,000 company to construct and operate an electric light plant.

Spokane, Wash.—It is reported that the Spokane & Columbia River Railroad Company has purchased a water right which it proposes to develop at an expenditure of $500,000 for the furnishing of electric light for Davenport and other towns.

Sylacauga, Ala.—The contract will soon be let for the erection of the new electric light and waterworks plant, for which bonds to the amount of $24,000 have recently been issued.

Turtle Creek, Pa.—The Rose Electric Light & Power Company has been incorporated with a capital of $20,000 to construct a power house. William L. Ledger is president.

Vidalia, La.—The Vidalia Light & Water Company, of which J. W. Wiggins is manager, will soon commence the construction of its $40,000 electric light plant.

Walnut Ridge, Ark.—S. C. Dowell of this city says that he will erect a $25,000 electric light plant at Pocahontas.

STREET RAILWAYS.

Ardmore, I. T.—The city council has granted to D. E. Lester, R. B. Lester and C. M. Jolner a franchise to construct an electric line. Right of way was given through the principal street of this city.

Aurora, Ill.—An electric line from here to Ottawa is being projected.

Carthage, Mo.—Jasper County is to have two additional electric lines. A. H. Rogers, president of the Southwest Missouri Electric Railroad Company, announces a new line from Webb City to Oronogo and Alba, mining towns, and a franchise has already been asked from the Webb City council for an independent line to extend over the same route. Isaac B. Craig is the latter applicant.

Clintonville, Wis.—Surveys for a new electric passenger and freight double track road, to be known as the Red River Valley Electric Railway, are nearing completion and it is expected that cars will be running by July 1. The road will begin here and end at Antigo, the line passing through Eland Junction, Matoon and Phlox. It is said that the road may also be extended to the Republic, Mich., iron mines. F. C. Delano of Philadelphia is chairman of the board of directors.

Durant, Miss,—The first permanent stake in the new electric interurban railways running from here to Lexington and Yazoo City has been driven by Mayor J. G. Hamilton. Chester Jones and W. O. Glines are the promoters of these railways.

Excelsior, Minn.—A formal application to the village council for an exclusive frachise to construct electric lines within this village has been made by Col. N. U. Hord of Philadelphia.

Grinnell, Ia.—O. K. Cole is promoting a company to build an interurban electric road out of this place.

Hopkins, Minn.—B. J. Phelps and E. Kenaston, who propose to constuct a trolley line from Minneapolis to Mankato, will ask the Hopkins city council for a franchise to enter this city.

Moberly, Mo.—This city is to have an electric railway. Joseph Clark, representative of H. S. Ramsey of St. Louis, has been here making preparations to build a power house.

Mexico City, Mex.—The Electrical Development Company of Mexico, which is controlled by the Mackenzie & Wann Syndicate, purposes to buy up the tramway lines in different cities of Mexico and install electric systems in each.

Vancouver, B. C.—The British Columbia Electric Railway Company will erect an electric line between this city and Stevenson on the Fraser River.

Wabash, Ind.—The Fort Wayne & Wabash Valley Traction Company has authorized a bond issue of $1,000,000 to be used in building a central power plant.

West Middlesex, Pa.—The Shenango Traction Company has been granted a right of way by the council of this city. Wheatland, Clarksville and Greenville have also granted franchises, and when the Sharon council takes favorable action the company will have a clear right of way from Cambridge Springs to New Castle. The road will cost $1,500,000.

POWER PLANTS.

Dillon, Col.—W. H. Foster of this city has purchased a site and will erect a large electric power plant.

Martinsburg, W. Va.—Capitalists of Washington and Baltimore, headed by Stevenson A. Williams, are said to be organizing a new stock company for the purpose of purchasing the old pulp mills and getting possession of the water power at Harper's Ferry, W. Va., where the erection of a big electric power plant is contemplated. It is said that stock to the amount of $150,000 has already been subscribed, and that the venture has assumed definite shape.

Mexico City, Mex.—A large electric generating plant is to be established in this vicinity by the Mexican-American Power Company, which was recently organized with a capital stock of $150,000. G. Stuart Simmons of New York is interested in the enterprise.

Morelia, Mex.—The government of the State of Michoacan has granted a concession to a syndicate of capitalists for the establishment of an electric power plant at a point on the San Pedro River in this State. The water of that river will be used to generate the electrical energy.

BIDS WANTED.

Birmingham, Ala.—The Eureka Foundry & Machine Company of this city wants prices on electric motors.

Camden, Tenn.—L. A. Wyatt, superintendent of the new electric light company, wants prices on a 700-light dynamo, direct current, two-wire, 220-volt.

Corydon, Ky.—The Corydon Milling Company wants prices on a generator to operate 300 to4 00 incandescent lights and a 50 hp. motor.

Holly Ridge, N. C.—A. M. Prince of this place is in the market for a 40 to 50 hp. engine and a 75 to 100 hp. boiler.

San Antonio, Tex.—J. B. Trescott, 406 Dallas street, this city, is in the market for one 150 hp. steam turbine or rotary engine.

Spray, N. C.—S. H. Marshall is in the market for one good second-hand 300 hp. Corliss engine.

Washington, D. C.—Sealed proposals will be received at the office of the commissioners until March 20 for supplying an electric generating plant for a sewerage pumping station. Address any of the following commissioners: Henry B. F. MacFarland, Henry L. West and John Biddle.

Waynesboro, Ga.—J. I. Linler of this city is in the market for a 50 or 60 kw. direct current generator.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 15⅛@15¼c.; Lake 15¼@15⅜c.; casting, 14⅞@15c.

The annual meeting of the Electric Storage Battery Company will be held March 15.

The Commercial Electric Vehicle Company of Jersey City, capital $1,000,000, has been incorporated.

The Toledo (O.) Urban & Interurban Railway, an electric line, has issued $1,000,000 bonds for construction.

The copper producing companies state they are assured of a 15-cent market for the first 6 months of the current calendar year.

Earnings of the Philadelphia Electric Company for January show an increase over the corresponding month of last year of $58,000.

The City & Suburban (Bell) Telephone Company of Cincinnati has voted to increase its capital stock from $4,000,000 to $5,000,000 to take in suburban lines.

At the annual meeting of the Marconi Wireless Telegraph Company, in London, England, it was announced that the net profits of the company for 1904 were $63,405.

The Bullock Electric Company of Cincinnati, the property of which is leased to the Allis-Chalmers Company, has been incorporated in Ohio with a capital of $2,500,000.

It is said that a syndicate of bankers, which has lately been prominent in acquiring electric lighting properties, has made an offer to lease the Electric Company of America of Philadelphia.

Announcement is made that a contract for electrical equipment, amounting to $175,000, has been awarded to the National Electric Company of Milwaukee by the Union Electric Light & Power Company of St. Louis.

The earnings of the Chicago Edison Company are said to be larger this winter than ever and the company is extending its field for supplying power to small manufacturing concerns. That business alone is said to have doubled within the last year.

At a special meeting of the stockholders of the Boston & Worcester Electric Companies, the trustees were authorized to issue 3,500 additional shares of common and 3,000 additional shares of preferred stock for the purpose of paying off the total indebtedness of the company.

Through its acquisition jointly with Delaware & Hudson of the Schenectady Railway Company the New York Central now holds firmly the control of the trolley situation up New York State. It is not now practicable for independent and competing electric lines to parallel New York Central tracks.

The Consolidated Gas, Electric Light & Power Company of Baltimore, a merger of the Consolidated Gas Company, the United Electric Light & Power Company and the Wenstrom Electric Company of that city, has been organized with Davies Warfield, president of the Continental Trust Company, as chairman of the new board of directors. The capitalization of the company includes 4½ per cent. bonds, $15,000,000; 6 per cent. prior lien cumulative stock, $700,000; 5 per cent. cumulative preferred stock, $6,000,000; common stock, $6,000,000. The mortgage of the Consolidated Gas, Electric Light & Power Company to the Continental Trust Company, trustee, provides for an authorized issue of $15,000,000, 4½ per cent. 30-year gold bonds, $8,639,000 of which will be reserved in the treasury for the future requirements of the company.

THE
Norton
ELECTRICAL INSTRUMENT
COMPANY
MANCHESTER, CONN; U.S.A.

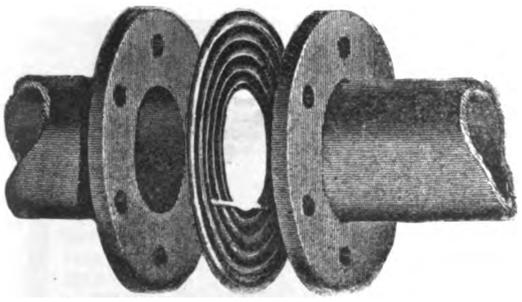
NORTON SWITCHBOARD INSTRUMENTS.

Style "C" in Ranges:

0 to 5 volts.
0 to 750 volts.
0 to 10 amperes.
0 to 1500 amperes.

Dead Beat and made for either Back or Front Connections.

The Norton Electrical Instrument Company,
Main Office and Factory, Railroad Avenue, MANCHESTER, CONN.



Joints Made Absolutely Tight and Durable by Patent Corrugated
COPPER GASKETS,
Furnished in all shapes and sizes for flanged PIPES, CYLINDERS, CHESTS, etc.
U. S. MINERAL WOOL COMPANY,
143 Liberty Street, New York.
BOURNE & KNOWLES MFG. Co., Cleveland, Ohio.

ECONOMIC ENGINEERING

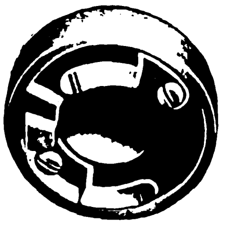
Designing and Building Special Machinery

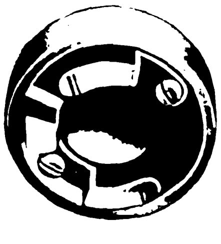
Elevating, conveying and storing materials in any shape or form—from one point to another, high or low—is a specialty with us.

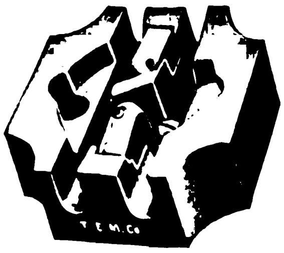
In designing, erecting and installing complete plants we have gained much valuable engineering experience. This expert knowledge is at the disposal of any prospective purchaser or engineer that's interested.

NEW YORK, 106 Graham Bldg. PHILADELPHIA, 716-718 Fidelity Mutual Bldg. (3) PITTSBURG, PA., 701 Empire Bldg.

THE AULTMAN COMPANY, CANTON, O.







NEW FUSELESS ROSETTES

Appreciated by all who have to do with wiring. May be fitted with cord and snapped on after the base is in position by merely a quarter turn of the wrist. Notice the stop in the cap. It can be put on only one way, so that in arc-light work there is no possibility of reversing the current by taking off the rosette cap.

CAPS INTERCHANGEABLE. FIT EITHER STYE OF BASE. Hole in cap takes new code cord. Sample sent prepaid.

Manufactured by

THE TRUMBULL ELECTRIC MFG CO.,
High Grade Electrical Specialties,
PLAINVILLE, CONN.
New York Office, 136 Liberty Street.

"ELECTRICITY,"
IS ONLY $1 A YEAR.

Pittsburg Sewer Pipe & Conduit Company

Manufacturers of

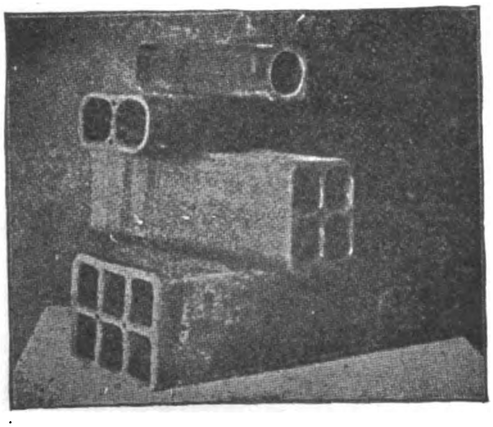
VITRIFIED CLAY CONDUITS

IN 1, 2, 3, 4 AND 6 DUCT.

Superior Conduits for underground wires a specialty.

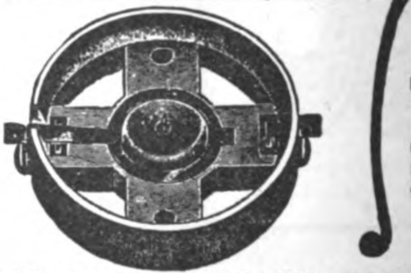
General Office and Factory:
PITTSBURG, KAN.

Branch Office and Sale Yard: 2417 East 18th Street, KANSAS CITY, MO.



The "Copenhagen"
Automatic Fire Alarm and Journal Heat Alarm.

THE ONLY ACTUALLY RELIABLE IN EXISTENCE. NO EXPERIMENT. IN USE SINCE 1889. SIMPLICITY ITSELF.



"Copenhagen" Thermostat. (¾ actual size.)

CANNOT GET OUT OF ORDER. DUST PROOF. ONLY HEAT CAN CLOSE CIRCUIT and NO LIMIT TO the NUMBER OF TIMES THIS CAN BE DONE.

You Cannot Afford to do Without the "Copenhagen"

BOOKLET FREE ON APPLICATION.
WE WANT FIRST CLASS MEN TO REPRESENT US.

COPENHAGEN AUTOMATIC FIRE ALARM CO.
SHEBOYCAN, WISCONSIN.

Dixon's Graphite Pipe Joint Compound

Makes the tightest joints that remain free from rust and come apart easily at any time. Write for Booklet 46-D and a sample.

JOSEPH DIXON CRUCIBLE CO., JERSEY CITY, N. J.

Linemen's Pliers,

With Insulated Handles 8 Inches in Length. Best Steel. Price $1 a pair. Address
ELECTRICITY NEWSPAPER CO., 136 Liberty St, New York.

ELECTRICITY.

VOL. XXVIII. NEW YORK, MARCH 1, 1905. NO. 9.

ELECTRICITY.

Published every Wednesday by the
ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.
Long Distance Telephone, 4021 Cortlandt

SUBSCRIPTION RATES:
United States, Canada and Mexico..$1.00
Foreign Countries.............. .... .. 3.00
Single Copies......................10 cents
Remit by Draft, Post Office Order, Registered Letter or in Stamps.

Owing to the expense involved in keeping back numbers, papers over two years old will be charged for at the rate of 25 cents apiece.

ADVERTISING RATES.

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than Saturday morning preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

EDITORIAL NOTES.

Facts and Figures that are Conclusive.

In view of the fact that New York City is committed to refuse burning for electric light, a few words as to what has and what has not been accomplished in this line in England, where the practice was originally started, may prove interesting.

Probably the first attempt to cremate refuse in a specially constructed furnace occurred at Paddington in England in 1870 and proved a complete failure. In 1876 a furnace for burning refuse, called by the inventor a "destructor," was erected at Manchester. This destructor proved successful so far as it went, in that it destroyed the refuse without it being necessary to burn an undue amount of coal and without the gases given off proving too obnoxious to the surrounding neighborhood.

It was not, however, until 1896 that a boiler was attached to the destructor furnace with a view to generating steam for power purposes. In that year the town of Oldham, finding that more steam was generated than could be utilized in the destructor works adjoining the electric light station, a steam main was carried into the latter and electricity from refuse-raised steam became an accomplished fact.

With Oldham as an example a number of destructor plants then shortly sprang up in various parts of England, and notably in the vestry of Shoreditch in London.

Elsewhere in this issue will be found an article on the subject of electricity production from refuse, especially prepared for ELECTRICITY by its London correspondent. The facts and figures given in this article were carefully gathered, sifted and digested with a view to ascertaining whether it pays and how well it pays to utilize refuse as fuel for steam-producing purposes. The conclusion reached may be summed up as follows: That the incineration of public and private refuse is the right process, but that the benefit obtainable from an electric generation point of view, though well worth having, must not be figured out too generously or disappointment will follow.

This conclusion, the result of careful study of facts and figures, should be considered and taken into account by the heads of our local municipal government before committing the city to a wholesale expenditure of money for garbage destructor electric light plants, which in the end may entail an enormous financial waste.

* * *

The People Awaking.

Protest against the exorbitant rates charged by the New York Telephone Company is still being made. The people of this city are at last really beginning to realize that the charges for service are too high, in fact much higher than in any other community in the country. That such is the case may be inferred from the fact that the rate for 1,200 telephone calls in Chicago is $105 a year, $91 a year for the same number of calls in Boston, and $87 in Philadelphia, where active competition with an independent company exists. In New York the local telephone company demands $1,100 a year for similar service.

ELECTRICITY has been endeavoring for the past eight years to bring about a more equitable schedule of telephone rates and has pointed out time and again in these columns that the people of this city were being imposed upon. It is therefore with pleasure that we learn that a joint public hearing has been fixed for

March 7, at Albany, upon a resolution for a legislative investigation of the monopoly's methods and charges. Meanwhile it is stated that the Board of Trade and Transportation may follow up its call for an investigation by bringing its influence to bear directly upon leading members of the dominant party in the Legislature. It is sincerely to be hoped in the interest of the people that the proposed investigation will not be sidetracked.

* * *

Electricity and Industrial Development.

A writer of novels, in commenting in the form of a toast, upon Edison's work, said: "Hail to Edison, Wizard of the Nineteenth Century and Monarch of the Twentieth." Perhaps this idea could now be construed differently without detracting in the least from the reputation of this inventor, by saying "Hail to Electricity, Wizard of the Nineteenth Century and Monarch of the Twentieth."

The influence of electricity upon industrial development has not been limited to a few widely scattered cases, but has become emphasized of late in connection with old and new enterprises of such a variety and such magnitude that it may well be accepted as an established fact that electricity has become monarch of the twentieth century.

Brilliant work has been done in the last decade which has so stimulated the field of electrical activities that electrical invention has overshadowed all other human achievements. The list of the new provinces representing this gigantic empire, which have been recently invaded and attacked are railroads, lighting, power, mining, signaling, telephoning, medicine and varied manufacturing. It is easy to glide over these subjects with but a passing interest, but the thoughtful men will see more than mere names in this incomplete list. Under the head of "varied manufacturing" the development through the use, if not entirely originated by electricity, is really sensational. Take the acetylene interests or the carborundum interests. Take the aluminum business alone with its many ramifications. Why, it seems as though the surface of things has only been scratched and the rich finds below are waiting for us.

The white goods manufacturers use electric power to the exclusion of all else; and those trades which are in any respect allied, and in which sewing machines are used, depend upon the motor for the normal output of their factories. The machine shops use the electric drive with individual control for each machine. The 40 per cent. loss in belts and shafting has gone and electricity, on tap whenever required, has been the means of removing unsightliness, uncleanliness, noise and inefficiency. In the pressure of manufacturing and business life, devices are required which do things quickly and well. The telephone and the telegraph are now regarded as indispensable. What a pitiable civilization this would seem without them—yet we have just taken the first full breath of freedom in this new atmosphere of electrical and mechanical progressiveness.

It is a fact that could hardly meet with denial from our historians of economic advancement, that industrialism and the force that is leavening it are natural associates at this era. There are some that step from behind the scenes and say, "Give us more inventions and there will be more workers, more consumers and therefore more wealth and prosperity."

The contributions of those who have been and are engaged in the origination, development and crystallization of useful ideas have come mainly from electricians. Great factories have grown as it were over night to yield the fruit of inventive genius, and it can be truly said that one million workers in the United States are now toiling as proof of the idea that associates electricity with our best industrial development.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

The city council of Elgin, Ill., has voted to lease the municipal lighting plant to the Elgin, Aurora & Southern Traction Company for 10 years. The municipal lighting plant was a losing investment for that city.

◆

It is announced that Signor Marconi will come to this country on his wedding tour, sailing March 18. While he is here, it is said, he will install another wireless station by which he hopes to greatly improve the wireless system.

◆

A large deficit is bothering the officials of Hamilton, O., as a result of that city owning its own electric light plant.

◆

Mr. Homer E. Niesz, editor of the Question Box for the National Electric Light Association, informs us that the first list of questions is being sent out to all electric light companies in the United States and Canada, also to electrical manufacturers, engineers, dealers and technical colleges. This list contains 444 questions, covering 26 headings. Answers are desired from all who are competent to reply to any one or more of the questions, and these replies should be sent to Mr. Niesz, 139 Adams street, Chicago, within 30 days.

◆

The executive committee of the American Street Railway Association decided to hold the next convention in Philadelphia during the week beginning September 24, at the Bellevue-Stratford Hotel.

◆

Mr. Lewis B. Stillwell, electrical director of the Interborough Rapid Transit Company, New York City, in a recent address said that "electrification of the elevated lines in New York has increased their capacity by one-third and has decreased by one-fifth the time spent on trains by the average passenger. It has demonstrated that the cost of maintenance of electrical equipment of rolling stock is materially less than that of steam equipment and it has proved that electricity can render more reliable service than steam."

◆

United States Consul-General Holloway, of Halifax, Nova Scotia, reports that $250,000 will be spent for improvements on the Welland Canal. Several bridges are to be rebuilt, and the canal is to be lighted by electricity, lights being placed every 200 feet.

◆

At the meeting of the executive committee of the International Association of Municipal Electricians, held at Erie, Pa., the date for the convention was set for August 29, 30 and 31.

◆

Prof. Ernest Rutherford, of McGill University, Montreal, has been appointed Silliman lecturer at Yale University for 1905.

◆

It is now proposed to fit lightships Nos. 71 and 72, which do duty on the dangerous Diamond shoals on the coast of North Carolina, with wireless telegraph outfits, and before No. 71, which is now at Baltimore, returns to the station, it is more than probable she will have an outfit aboard with experts to run it. The installation of wireless telegraphy aboard the lightships is a part of the strategical scheme of the Navy Department to connect the entire Atlantic coast by wireless telegraphy. The wireless service aboard the lightships on the Diamond shoals would be valuable, as quick notice could then be given of vessels in distress and quick succor could reach them.

GARBAGE DISPOSAL AND ELECTRICITY PRODUCTION.

A POINTER FOR NEW YORK AND OTHER LARGE CITIES.

(From our London Correspondent.)

For several years past criticism has been very freely showered upon the municipal ownership and operation of electric lighting and other systems in England. And that a great deal of this criticism is justifiable is proved up to the hilt by the abundant evidence that is forthcoming from many parts of the United Kingdom to the effect that a very large percentage of the undertakings are not working at a profit to the ratepayer. The criticism, however, has not been so effective in its attempted application to the larger cities, such as Glasgow, Liverpool, Sheffield, and so on; it has mainly effected the smaller towns and districts, and as a result a number of these have been only too willing to pass on the responsibilities of electricity supply to the larger power distribution companies who supply many towns within a wide area, or to companies owning a dozen or more concessions situated many miles apart, but all under one central and therefore economical management. There is one branch of municipal enterprise which has been particularly free from attack, and that is refuse destruction by the process of incineration. There is a feeling that matters affecting the public health in any particular degree are best left in the hands of the public authority. The progress has been really remarkable. The dust destructor as a means of getting rid of objectionable matter in a sanitary way is universally regarded as the best means yet produced; but, though there has been no difference of opinion, and no criticism worth mentioning on that point, there has been criticism and there has been diversity of opinion as to the benefit likely to accrue from the combination of the destructor with an electricity generating station.

The correct attitude, and one which has been adopted by many English electrical engineers, may be described thus: The primary object of refuse destruction is the disposal, in a sanitary manner, and rendering innocuous all waste materials collected from the private house dust-bins and trade refuse. If, at the same time, not only can this object be realized, but some useful product obtained by so doing, without any corresponding disadvantages or drawbacks, the cost can be materially reduced, and the financial aspect of the question becomes more favorable.

Speaking approximately, 200 towns at least in the United Kingdom and Ireland have adopted refuse destructors. We think we shall be on the low side if we say that about one-third of these have adopted the combined idea—the electricity works plant receiving the aid of the steam raised from the refuse burning. The progress that has been made during the past five or six years will be realized when we say that previous to the year 1899 there were only two or three combined undertakings in operation. The majority of the destructors so combined are of the Meldrum type, most of the remainder being of the Horsfall design.

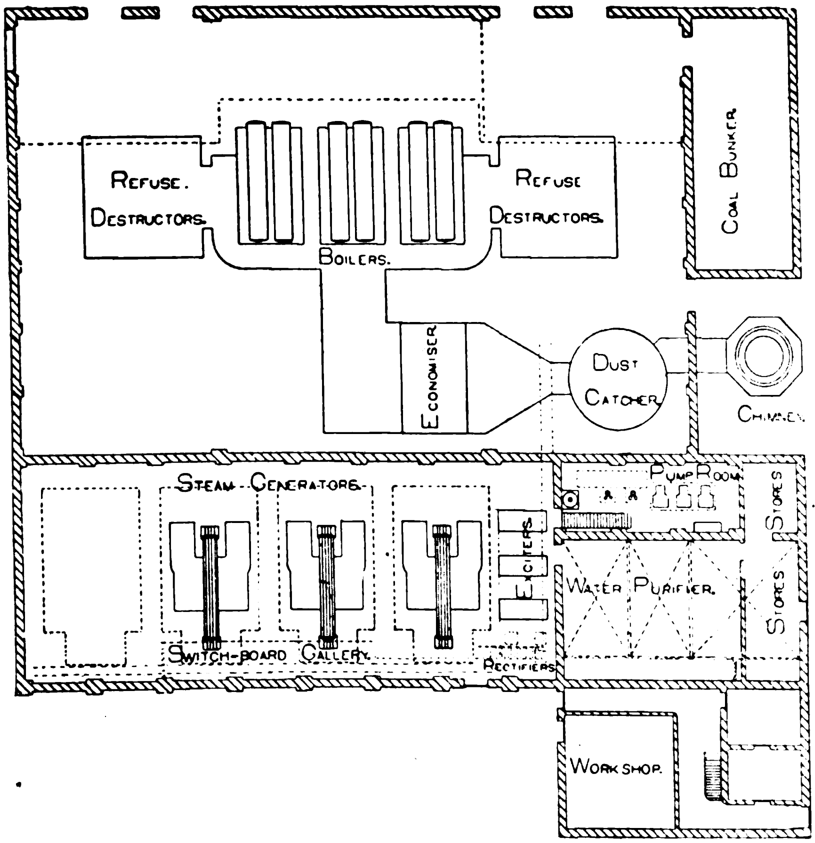
There has been much discussion among English electrical engineers recently as to the results which have been obtained, and the figures which have been put forward by some experts have been so severely handled by others that it is not the easiest thing in the world to say which plants have actually recorded the best performances. A test made by the National Boiler Insurance Company of a Meldrum plant of fairly large size at Woolwich, showed that during the evening hours, when the electrical department could use all the steam produced by the destructor, the output of current was just about 100 board of trade units per ton of refuse burned. Messrs. Meldrum, in summarizing the results of hundreds of tests made by them, show that with ordinary average English town's refuse the Meldrum destructors will produce from 1½ to 2 pounds of steam per pound of refuse, proving that the utilization of this power to the utmost extent for municipal purposes is a matter of great importance, more especially, as we have said, now that destruction of garbage by fire is becoming considered an almost absolute necessity in most, if not all, leading cities and towns in England, and many on the European Continent, and others in South Africa, etc.

Perhaps we may now mention a plant of the Horsfall type. Let us take that of Fulham, where about four years' experience has been obtained of the working of 12 cells of the Back-to-Back top feed type. The refuse to be destroyed every 24 hours was 120 tons and the total horse power available from the combustion of this refuse was 600 IHP. The cells are arranged in two groups of six each on either side of six Babcock & Wilcox boilers. The tipping floor is arranged to allow of the storage of a considerable amount of refuse, so that the working of the plant may be continued without interruption. There are not wanting experts, who, however, offer strong criticism of any extensive storing of refuse because it is unmistakably insanitary. Access to the tipping floor at Fulham is obtained by means of an inclined roadway, at the foot of which all refuse received is weighed and a record kept. Each boiler has a heating surface of 1,284 square feet. The destructor gases are led into each of the boilers by means of an opening in front of the bridge, the flue to this opening being provided with a suitable damper so that the boiler may at will be heated from the destructor or fed with coal. It was expected when this plant was put in that the electricity department would be saved the cost of 2,000 tons of coal per annum. The calorific value of the Fulham refuse was said to be one-twentieth that of good steam coal. With regard to the results obtained from this system, Mr. A. J. Fuller, the borough electrical engineer, asserts that he is now getting from 50 to 70 electrical units per ton of refuse. In comparing this with the figure obtained at Woolwich it must be borne in mind that the 100 units there stated were secured at the evening "peak of the load" hours, not an average.

It is hardly necessary in facing the position of matters as they stand to-day to mention what was done several years ago when pioneering plants were put down at Shoreditch, St. Pancras, Ealing, etc. In the putting down of such plants to-day engineers and others have profited by the early experimental experience of these systems, which were kept working for a time and were subsequently found to be of no benefit to the electric light and power plant, and in at least two cases were discarded. Like all things, there has in this case had to be a trial and error stage from which we seem to have now emerged.

Not very long ago one of the important borough councils of London instituted through its chief electrical engineer (Mr. G. G. Bell), and its surveyor (Mr. Mair), a very full inquiry into the wisdom or otherwise of adopting a destructor. The report has some interesting points which have perhaps some bearing on the position which has arisen in New York in connection with the proposed municipal electric lighting and destructor scheme, and we are enabled by the courtesy of Mr. Bell to make some extracts from his statement:

"In the first place, there is no doubt whatever that a proper system of refuse destruction is the most sanitary method of dealing with the house bin refuse collected from large communities, as it can be dealt with close at hand, thus avoiding the risks and cost of transit to the dust shoots which must of necessity be some distance from the large centers of population. The question of cost, however, is to a very large extent the ruling factor, and as the available shoots near at hand are gradually filled up this simple method of dealing with the matter becomes more and more expensive, although from a sanitary point of view it does not materially affect the persons whose refuse is carted away. Dust destructors therefore really affect the community at large, and if the cost of dealing with our refuse by means of a dust destructor is heavier than by sending it away we are paying this extra money simply for a more ideal state of affairs.



General Arrangement of Destructor Plant at Fulham.

"The perfect dust destructor has not yet been designed, and should be a combination of the following points, but there are some very good approaches to it upon the market:

"1. Perfect cremation of the refuse so that there can be no offensive nuisance from partly burned gases.

"2. Must be capable of dealing with the refuse immediately it is delivered, so that it is not necessary to store same as it quickly becomes offensive under these conditions.

"3. No nuisance to the surrounding neighborhood through fine dust or grit being distributed from the chimney stack.

"4. The furnace temperature should be so great that the residue is melted and forms hard clinker which then becomes a useful by-product.

"None of these points should be sacrificed in order that the refuse should be used instead of coal for any useful purpose, and if these points can be fully met and any surplus heat used for generating steam, then this steam may and should be used for driving the necessary machinery required in the destruction of the refuse, and we believe that there would be very little, if any, heat available for any other useful purpose.

"It would perhaps be as well to examine the conditions which prevail at Hammersmith and ascertain the cost of erecting and working a destructor, and also see if any useful purpose could be served by the apparatus after its true functions have been carried out. The actual amount of dust bin and trade refuse dealt with last year was approximately 28,000 tons, but as the population of the borough is continually increasing, any destructor erected should be capable of dealing with 30,000 to 35,000 tons per annum, which taking 300 working days in the year will give an average of about 100 tons daily. The cost of the necessary dust destructor, as well as tipping floors, boilers, dust catcher, buildings and chimney, would be about £18,000, to which must be added the cost of the land. The area required would be approximately one acre, as provision must be made for a necessary inclined approach road, stores and other buildings.

"When the refuse has been tipped into the destructor cell this is not the end, as there is a very heavy residue to be dealt with, which varies from 25 to nearly 50 per cent. of the total quantity placed in the cell. This must be disposed of in some manner or other as rapidly as it is made, and where building operations are in active progress or a large number of new roads and streets are being made up in the district it might be disposed of, but in our case, where sand is abundant and the number of new roads to be made is extremely small, we believe there would be difficulty in disposing of approximately 10,000 tons of clinker without barging away.

"To deal with the refuse by the destructor would cost £5,699 per annum including financial charges but the cost of barging away dust at the present time is 2s. 7d. per ton, which at 30,000 tons per annum equals £3,875, showing an increase of £1,824 per annum.

"Of course it is possible to use the hard clinker for manufacturing artificial stones for paving, but the plant necessary to do this, i. e., mills, crushers, hydraulic press, etc., would cost a further £2,000 before we could deal with this clinker satisfactorily and economically. Taking it for granted that we should be able to get rid of the whole of the clinker, the question arises as to whether any surplus steam which the destructor would generate could be utilized for any useful purpose. This entirely depends upon the amount of steam and the steadiness at which the supply can be maintained, as of course an intermittent supply would not be of any use from a commercial point of view. The question of combining destruction and electricity generation is one turning upon the calorific value of the refuse, and the position which Hammersmith occupies does not justify one in looking for a very high calorific value for the following reason: It is not the center of any very large industrial activity, so that the amount of trade refuse is absolutely a negligible quantity; it is not the center of a rich residential district, so that the amount of combustible material in the house dust bins is reduced by the residents to the lowest possible denomination. An examination of the refuse tipped will bear this out, and in fact we are afraid that in order to obtain a sufficiently high temperature to insure perfect cremation of the gases it would perhaps be necessary to add a little coal to the refuse to obtain this result.

"If we are fortunate enough to burn the refuse without the aid of coal then the surplus heat, after driving the necessary plant for producing the forced draught, lighting the building, driving any artificial stone machinery, etc., will be such a negligible quantity that it is not safe to allow any credit for this in making out the estimates. Taking the average cost per ton, as previously shown, we arrive at a total cost of 3s. 9½d., which we think is a fair estimate, and may be taken as the average cost.

"The actual ascertained cost at Fulham is 3s. 7d. per ton, before, however, allowing a sufficient sum for depreciation, and working a more expensive plant suitable for assisting the electric light works.

"Upon examination of the annual returns of six London municipal electric light stations, three of these having the assistance of destructors and three with coal only, the following comparison shows the value of a dust destructor: Capital expenditure per kilowatt of non-destructor stations, £80; capital expenditure per kilowatt of destructor stations, £118. The working costs of non-destructor stations is 2d. per unit higher than the destructor stations, which, upon 5,774,644 units (their total output) represents £4,895. The extra cost of the capital involved to effect that saving is, apparently at 5 per cent., £7,395, showing a net loss of £2,500 per annum as the cost of combining dust destructors and electric light stations.

"Turning again to the Fulham result, the resident engineer reports that the value of the fuel saved by using dust was £2,260 per annum which, however, we find would be turned into a loss of about £200 if a proper amount were set aside for the depreciation of the special plant.

"We have arrived at the following conclusions: (1) That barging away is more economical at the present time; (2) that the refuse has not sufficient calorific value to justify the combination of a dust destructor with the electricity works; (3) that there is every probability that the cost of cremation of refuse will greatly decrease, whereas the cost of barging is more likely to increase."

The exponents of the cause of refuse destruction in England have themselves thrown cold water upon the wonderful claims that some advocates of the combination have set up, and we cannot do better than quote in this connection the tement of Mr. W. F. Goodrich, one of ding authorities on the question. t the harm done years ago by rdinary claims regarding the gold in the dust-heap" has had its effect ever since. Results in power production were prophesied which have not yet and never will be obtained. The modern destructor has an excellent record, but it has its limits."

The conclusion of the matter still is that the incineration of public and private refuse is the right process, but the benefit obtainable from an electric generation point of view, though well worth having, must not be figured out too generously or disappointment will follow.

ENGLISH FIRE ENGINE PORTABLE ELECTRIC LIGHT PLANT OPERATED WITH LIQUID FUEL.

BY FRANK C. PERKINS.

The accompanying illustrations and drawings show the details of construction and method of operating a new English portable electric light plant for fire department service, with liquid fuel. This equipment was constructed for the Liverpool fire brigade to meet its needs, as indicated by the chief superintendent, Mr. Thomas. This fire engine electric light plant was built by Messrs. Merryweather & Sons, of Long Acre, London, and is equipped with a complete telephone system. The direct current dynamo utilized is of the inclosed type, mounted, as shown, on top of the outfit, the lamps, provided with handles and guards, being connected to flexible cables on reels. The drawings show the details of a special burner for utilizing liquid fuel stored in the tanks, designed by Mr. I. I. Kermode, C. E. A jet of steam from the boiler from a valve at A, is used to pulverize or spray the oil in this burner. A guage, D, shows the pressure under which the jet is operating, and a valve, B, provides for adjusting this pressure. One of the tanks on the engine is used for feed-water and the other, H, for the oil supply through the valve, E, passing to the burner entering the furnace at J, as indicated in the drawing. The drawings of the burner indicate that the oil will have a whirling motion, caused by the construction of the oil valve stem. The oil supply is entirely steam jacketed, as will be noted in the drawing, which indica that the steam enters around the

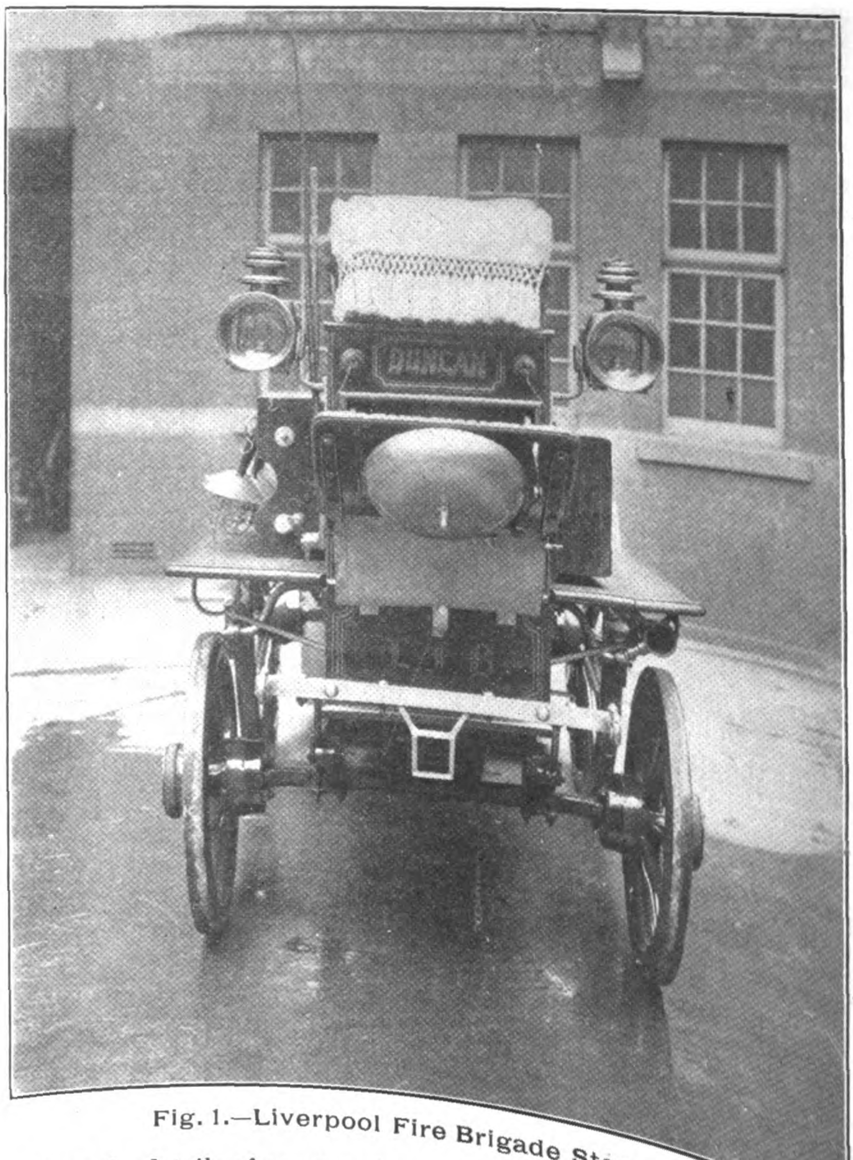


Fig. 1.—Liverpool Fire Brigade Steamer.

cone and then passes into the cylindrical portion through slots. The cylindrical portion fits in the hollow of the air cone, the latter being fitted with spiral guides and the air drawn in through the same by the action of the steam. The amount of air drawn in is adjusted by closing or opening the spaces provided for the purpose. The range of the burner is said to be such that the flame can be turned down so as to barely keep the boiler working, and it is claimed that little or no smoke is sent out of the stack, as complete combustion is obtained.

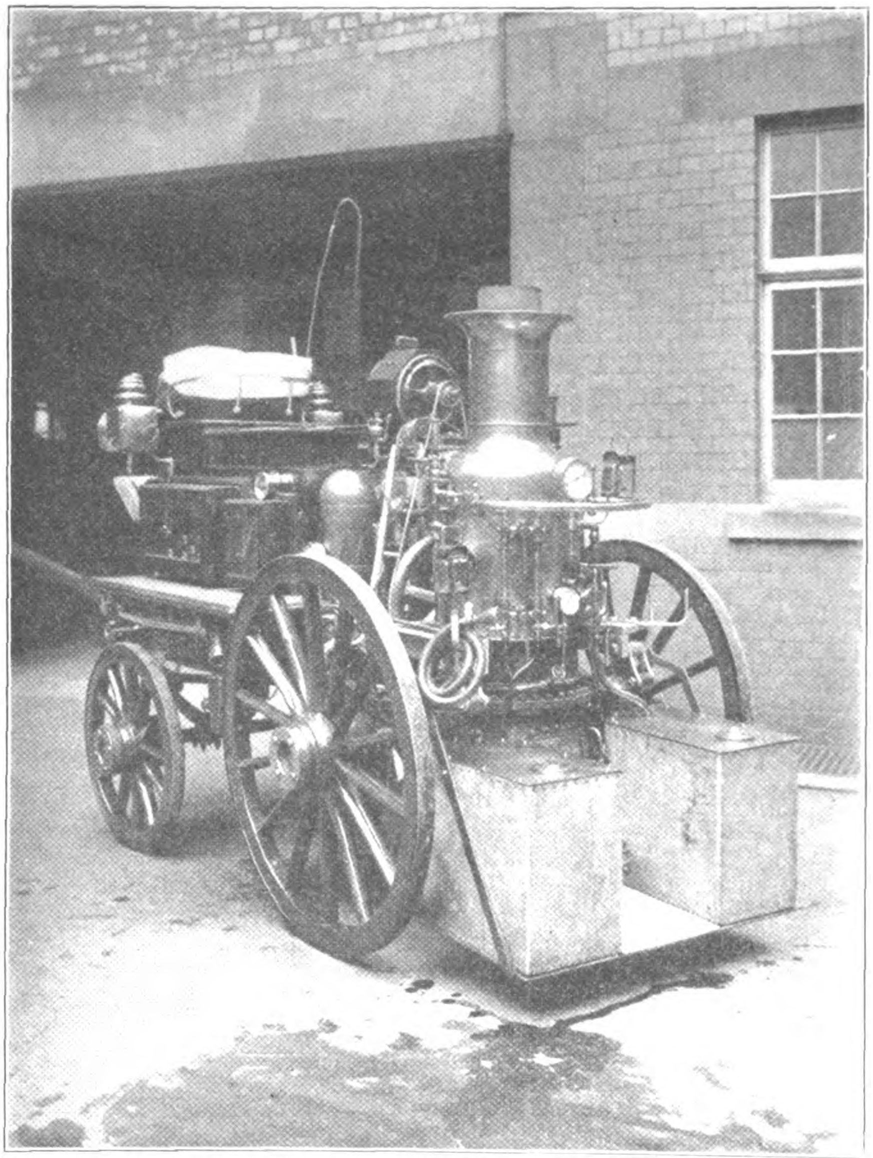

Fig. 2.—Liverpool Fire Brigade Horse-drawn Fire Engine.

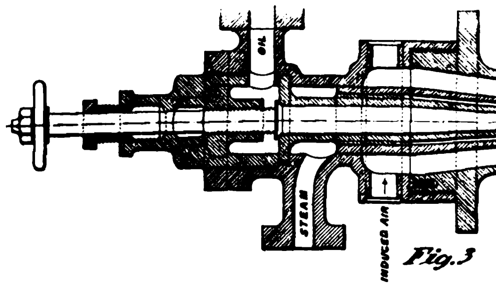

Fig.3

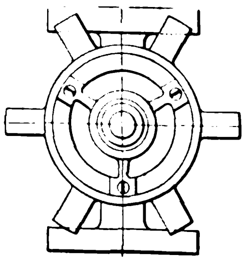

Fig.4

Fig. 5.

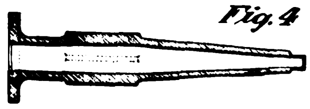

Fig. 6.

The burners work with a steam pressure of 16 to 20 pounds per square inch, but until the pressure has reached 10 or 15 pounds per square inch the oil burner cannot be used, and the fire must therefore be started with solid fuel in the ordinary way. However, by adding to the engine a cylinder containing compressed gas or air, this drawback has been overcome, as with this compressed air or gas the oil burner can be started and kept at work until the steam pressure has risen sufficiently for it to work the burner. The gas is compressed to a pressure of 100 atmospheres and is carried in an ordinary gas cylinder, about 18 inches long and 5½ inches in diameter, containing 20 cubic feet of air or coal gas. With this addition the oil fire can be started immediately and there is thus a saving of time needed to get up steam, which can be raised to 40 pounds pressure in 8 minutes.

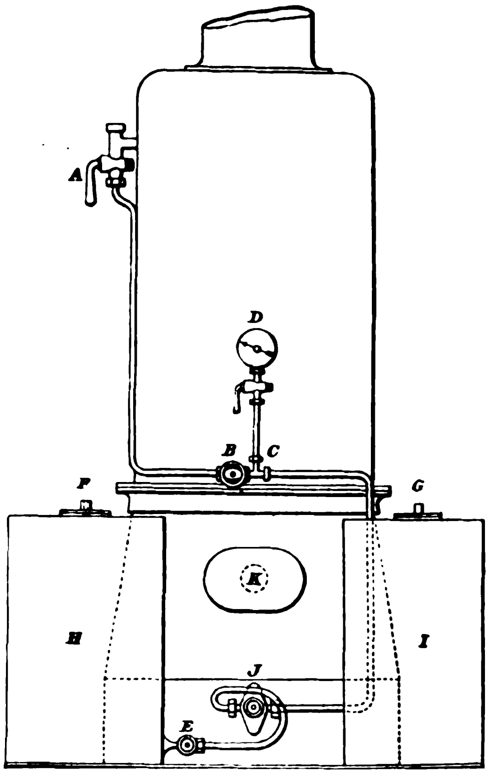

Fig. 7.

When 15 pounds of steam is on the boiler the gas is shut off and steam used direct from the boiler. The cylinder is filled inside the feed-water tank, which is at the right hand side in the illustration. For fire brigades, where steam is not kept up on the boiler continuously, the fitting is invaluable as the charge stands ready for instant use and it is available for any length of time provided there is no leakage. This fitting is especially

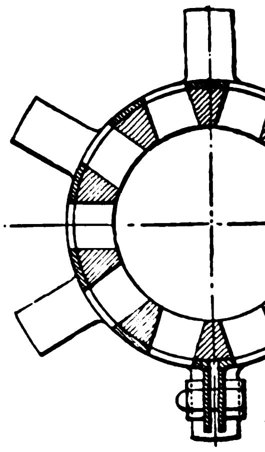

Fig.8

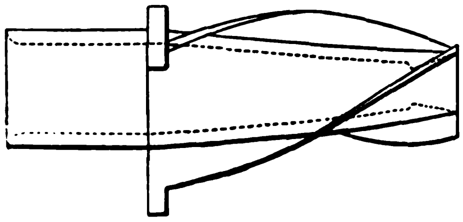

Fig. 9.

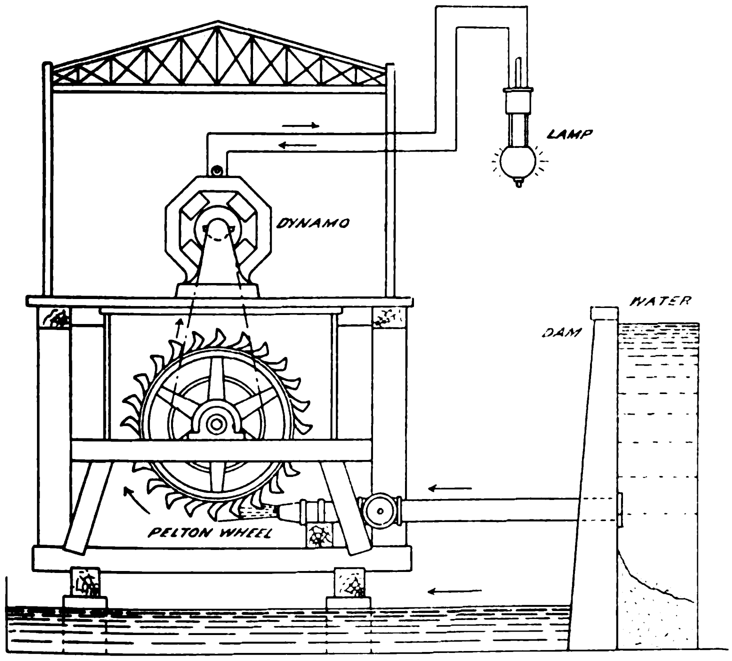
valuable for suburban or private fire brigades where an engine is seldom used. The Liverpool fire brigade is supposed to be the most thoroughly equipped brigade in the world. Its oil-fired engines are general favorites, being in constant use and always ready with steam up.

ELECTRICITY LEAFLETS.

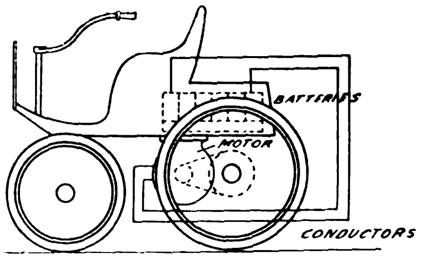
BY NEWTON HARRISON, E. E.

THE MOTOR.

Oersted's Discovery.—The reversibility of dynamos and motors operated by a continuous current is of enormous advantage in the practice of electrical engineering. The same is true of single-phase generators which, of course, are producers of alternating currents, but in this case the one to be run as a motor must be speeded up to synchronism, otherwise it will not run. When this synchronism ceases the motor fails to rotate. The two and three-phase machines are also reversible, as shown by the operation of rotary converters, in which that part of them in which such currents are generated or used are readily reversible. The continuous current motor possesses many features of simplicity and economy which raises it as a power producer far above the plane of all other devices with the exception of the water turbine. In this exception the efficiency, however, rarely exceeds 85 per cent., whereas in large motors it reaches a figure 10 per cent. higher or 95 per cent. The fundamental principle on which the operation of either a direct or alternating current motor rests is a corollary to the all-embracing principle of the conservation of energy. A motor is a machine in which electrical energy is transformed into mechanical energy. This is the converse of the dynamo, which is a machine in which mechanical energy is transformed into electrical energy. To transform electrical energy into mechanical energy the medium of the electro-magnet comes into play. The transformation is only accomplished, in the accepted sense of the word, in the case of motors by means of magnetism. Fundamentally all motion which results in rotation is due to the operation of the two simple laws that unlike poles attract and like poles repel. These poles are produced by electricity and by their relative positions with respect to each other, which also calls for either parallelism or a lack of parallelism in their respective fields, induces continued rotation. The development of a magnetic field within a loop of wire, when affected by a current of electricity by which it possesses all the qualifications of a magnet of equal dimensions, was first discovered and enunciated by Oersted. Thus it became subsequently possible to express magnetism qualitatively and quantitively in terms of electricity. In other words, it was found that magnetism produced by electricity could be calculated with exactitude, and the polarity as well, anticipated. Each turn of wire carrying a certain current can be regarded as a lamellar magnet possessing a certain magneto-motive force. A succession of such small magnetic pumps, as they might be called, force the magnetism through the medium whether it be iron or air. As the number of them are increased and the current in them increased their power or magneto-motive force increases in proportion. Thus, when such coils are so situated that their influence upon each other is productive of motion, it becomes evident that the power produced mechanically is in proportion to the extent of the pull resulting from such a co-operation of faces and the rapidity of motion it engenders.



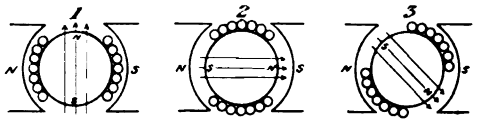
A Generator Absorbing Mechanical Power and Giving Out Electricity.



A Motor Absorbing Electricity and Giving Out Mechanical Power.

Power, then, in a motor can be measured by the speed of rotation per minute, and the degree of pull or torque accompanying it. These are things depending upon the fundamental idea of turns and current, commonly called ampere turns.

Relation of Lines of Force and Current.—The magnetic whirl surrounding a wire becomes more intense the heavier the current in the wire. These whirls spread out in ever widening circles, the center of whose vortex is the wire itself. The magnetism or lines of force, when meeting those of another field, tend to set themselves parallel, or as it would seem, tangent. When a bar of iron is inserted within a series of electro-magnetic helices its polarity becomes most pronounced and manifests itself, if movement is possible, by moving towards an opposite pole or away from a similar pole. When the magnetic field of a motor is considered, its lines of force pass between the two poles via the armature core of laminated iron placed within it. A coil of wire wound around this core can occupy a series of positions with respect to the horizontal or vertical plane. Let three positions be considered—one in the horizontal plane, one in the vertical plane, and one in a plane situated at an angle of 45 degrees. This coil as yet has exercised no influence upon the magnetic field which streams across from the north pole to the south pole of the motor. It is now to be considered as occupying the first of the positions referred to, namely, the horizontal plane.



1—Armature Coil in Horizontal Plane. 2—Armature Coil in a Vertical Plane. 3—Armature Coil in a Plane of 45 degrees.

A Coil in the Horizontal Plane.—On sending a current through the coil when in this position in the horizontal plane it acts in every respect as any other electro-magnet irrespective of the fact that it is already in a magnetic field. The turns of wire which compose it act upon the armature core of laminated iron which they embrace, and magnetize it. If a coil were in a horizontal position in space, and did not contain any iron, it would produce a comparatively weak field, whose lines of force would lie in a vertical direction. Situated as it is with a core of wrought-iron between the poles of a powerful field the same phenomenon takes place. The coil produces a vertical field, a field in fact whose lines of force are at right angles to those of the original field. It would tend to move the now vertically suspended electro-magnet so that its poles would seek the opposite poles of the surrounding field. The motion would be under the circumstances one of rotation either to the right or to the left, depending upon the relative position of the poles produced by the ampere turns of the horizontal coil and those of the field in which the armature core rests. If it is situated in an absolutely horizontal plane so that the lines of force are truly vertical and the lines of force of the field are absolutely horizontal, then a resultant field would be found. Two magnetic forces acting at right angles to each other, according to the elementary laws of mechanics, must produce a resultant force. The field would therefore be twisted and operated at an angle to its former position. The lines of force of the coil will, if permitted, set themselves parallel to those of the field, and in so doing motion would be produced.

A Coil in the Vertical Plane.—A coil so situated produces a magnetic field at right angles to itself or in a longitudinal plane. Its lines of force would therefore merge with those of the surrounding field or, if the poles were opposed to each other, reduce it to an extent dependent upon its magneto-motive force. In either case, whether the field is augmented or reduced no motion will tend to result from such a relative position, as the lines of force are now in a position of parallelism with respect to each other.

A Coil at an Angle of 45 Degrees.—It is evident from the positions of the coil in a horizontal and vertical plane that these are not the ones best suited to the production of either great pull or torque or motion, A coil at an angle of 45 degrees however, producing a magnetic field at right angles to itself, would also present poles in a position with reference to those of the field surrounding it such that motion must result. Not only will a tendency to swing around be perceived, but a strong pull will accompany it. The lines of force of the coil can set themselves parallel to those of the field only by moving the core. This will actually take place not only when coils occupy a position at 45 degrees to either the horizontal or vertical plane but when they are slightly inclined to either. Thus it becomes evident that the constant effort taking place between the lines of force due to the coils on the armature and those of the field, which are supposed to remain comparatively unchanged, can only take place when they occupy certain positions with respect to the field. Under these conditions it might be said that the circumstances present the case of one fixed magnet whose field generally retains its position and a series of movable electro-magnets whose fields are constantly assuming positions in which their lines of force lie parallel to and in the same direction as those of the field. Increasing the current under these general conditions would mean an increase in pull between the stationary magnet of the field and the movable electro-magnet caused by the various positions of the coils on the armature. The torque of the armature therefore is entirely a question of magnetic field and current in the armature, which is merely another way of saying that it is simply a question of the amount of pull resulting from a stationary and a movable magnetic field, the latter being capable of accentuation by an increase of current.

Magnetism and Mechanical Pull.—The relations existing between magnetism and mechanical pull might be construed as the relation existing between these two items and the current. In the case of an electro-magnet, to the poles of which a piece of iron or armature is to be attracted the formula is very simple. The formula gives the pull in dynes and calls for the lines of force of the poles to be given in lines of force per square centimeter as follows:

Pull in dynes = (lines of force per sq. cm.)^2 × sq. cms. ÷ 8 × 3.1416.

Or it may be written

$$P = \frac{B \times B \times A}{8\pi}$$ on the same basis

where P = pull in dynes,
B = lines per sq. cm.,
A = sq. cms.,
π = 3.1416.

To illustrate the application, take the case of a magnet having 100 sq. cms. of pole surface and the lines of force equal to 10,000 per sq. cm. The calculation will show the following result:

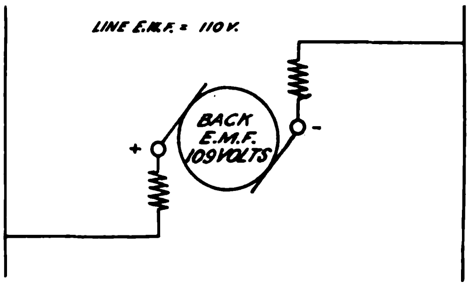
$$P = \frac{10{,}000 \times 10{,}000 \times 100}{8 \times 3.1416} =$$
386,347,721 dynes = 868 pounds.

The increasing use of electro-magnets for lifting purposes is one of the indications of the facility with which such a device can be employed in large foundries and steel works, where large masses of iron must be firmly seized and lifted.

The Back EMF. of a Motor.—The adjustment which takes place between the load of a motor and the power it consumes is brought about by means of the back electro-motive force. This EMF. is developed within the armature for the same reason that any other EMF. is generated in conductors cutting a magnetic field. The armature of the motor, though caused to rotate by the reaction between the field of the magnets and the field of the conductors, nevertheless presents the case of free conductors rotating in such a manner that the lines of force they meet are cut and necessarily produce EMF. It is a simple matter to calculate this back EMF. by multiplying the revolutions per second by the number of conductors by the lines of force of the field and dividing by 100,000,000. The conditions which exist within the armature of a motor when in action therefore are as follows: Current is allowed to enter the motor, energizing the field magnets, and passing through the armature in a limited manner. The rotation which then ensues is the means of generating an EMF. within the armature conductors. There is therefore two electro-motive forces in action within the armature; one of which tends to send a current through it, and the other, which opposes or counteracts the effect of the entering EMF. If the EMF. *generated* within the armature conductors is called the back or counter electro-motive force, the EMF. applied to the motor can be called the line or impressed EMF.

How the Back EMF. Varies.—A study of EMF. with respect to its generation by means of motion, lines of force and conductors, shows how variations in the amount of EMF. developed may be brought about. Any increase in the number of conductors on the armature of a motor will give rise to a higher back EMF. Any change in the speed of a motor will give rise proportionately to an equivalent change in the back EMF. of a motor. And finally any increase or decrease in the strength of the magnetic field will be the means of causing a change in the back EMF. These influences are thus referred to because the regulation and operation of motors is dependent upon these principles not only in theory but in actual practice.

Load and Back EMF.—When an impressed EMF. acts upon the field and armature windings of a motor, current is sent through the first, producing a field of given strength, and through the second in developing rotation and its concomitant power. The remarkable fact about the work a motor is doing and its back EMF. is this: When the motor is running free, or "idle" as it is called, the motor is developing the highest back EMF., and in consequence the impressed EMF. is only able to send a small current through the armature. The effective EMF. in this case is the *difference* between the impressed EMF. and the back EMF. This effective EMF. will send a current through the armature which is governed by the resistance of the same. For instance, if the armature has a resistance of .01 of an ohm, the impressed EMF. equals 110 volts and the back EMF. equals 109.5 or 109.75 volts. The difference between 110 and 109.5 volts is .5 volt, which with a resistance of .01 of an ohm would mean a current of $.5 \div .01 = 50$ amperes. The difference between 110 and 109.75 volts is .25 volt and this would send a current through the armature of $.25 \div .01 = 25$ amperes. Therefore a very low resistance armature needs but a very small effective pressure to send a heavy current through. The frequent changes of load to which a motor is exposed will when taking place vary the speed slightly. If the load is reduced the speed will increase, and if the load is increased the speed will diminish. It is thus evident that the back EMF. will vary accordingly, and that less or more current will pass through the armature. The back EMF. therefore acts as a natural automatic valve which opens wider when the load on the motor is increased and therefore more current is required, and which, so to speak, closes when the load on the motor is diminished and less current is required.



Armature Receiving Current through Difference of Line and Back EMF.

Electricity in Mills and Mines.

Electricity is beginning to play a prominent part in the operation of both mills and mines in Colorado. In the mines the incandescent lamp has largely taken the place of the miner's candle, trolley cars have replaced the car propelled by mule power and the old time steel and single jack is displaced by the electric drill. In many instances hoists are operated by electricity instead of by steam. Electric pumps for several mines in that State are the latest things by which electricity can be utilized in the mining of coal. One company states that the cost of making the change will reach several hundred thousand dollars, but this will soon be saved by the reduced cost of operation.

* * *

TWO MOTOR VERSUS FOUR MOTOR EQUIPMENTS.

In railway work a variety of problems arise, connected with the growth of the city and the density of the population. The development of a street railway is governed by these and other conditions such as the number of grades met and the degree of acceleration required. In a paper read before the American Institute of Electrical Engineers February 24, 1905, Mr. N. McD. Crawford discussed "Two Motor vs. Four Motor Equipments" for the purpose of ascertaining the relative advantages and disadvantages in the way of commercial efficiency associated with trials of this description. Four cars were selected bearing the following numbers: No. 169, 138, 101 and 480. In order to present the data relative to these cars in the most convenient form it is tabulated as follows:

No. car.	Body.	Trucks.	Cost.	Weight. Tons.	Horse-power.	Gear Ratio.	Commercial efficiency.
169	20 feet.	Single.	$2,710	9.075	Two 25 motors	1 to 4.87	17 %
138	26 feet.	Two.	3,275	12.425	Two 35 motors	1 to 2.82	13.11 "
101	26 feet.	Two.	4,360	14.675	Four 35 motors	1 to 2.82	12.53 "
480	29 feet.	Two.	5,040	20.680	Four 40 motors	1 to 3.67	10.66 "

The test with two 2 motor and two 4 motor cars and their equipments was conducted fairly and equally. The distance covered by every car was the same, namely, 136.5 miles each day; and the rate of speed represented on an average 8.45 miles per hour. A careful record was kept of the changes in power by means of a wattmeter in each car; and the variations in current and pressure were noted also by means of a voltmeter and ammeter installed in each car. For the benefit of the reader it may be stated that two important records were also taken, during periods of acceleration, and when grades were being climbed. The idea of acceleration is one of vast importance in street railway work and may be best understood by the explanation that if one car can accelerate quicker than another, it can leave a given spot in a shorter time with an equal weight of passengers. Therefore the figures that were taken in the course of this test, which indicated the power consumption during the acceleration, and the hill or grade climbing, represent a basis of comparison of the greatest interest. The cars with their equipments subjected to the run of miles, and rate of speed noted, gave a series of efficiencies which, in connection with the weight of each car in tons, the seating capacity, cost per seat and cost per ton, constitute an excellent table of reference. The highest commercial efficiency was obtained from No. 169, whose seating capacity was 26 representing a car costing $2,710, and yielding an efficiency of 17 per cent. This high efficiency, in comparison with that of the other three cars, which were only 13.11, 12.53 and 10.66 per cent. respectively, was the result of the particular circumstances under which the test was conducted. Car No. 480 had the lowest efficiency, which in connection with the other cars and their equipments brings out a point of particular interest. In order to appreciate it, the list of motor equipments must be scanned, and it will be noted at once, as the eye travels down the list, that the weight and power of the motors increases in each car.

That is to say, cars No. 169, 138, 101 and 480 represent total weights of 9.075, 12.425, 14.675 and 20.680 tons respectively.

But it will also appear that the efficiences of these cars under test resulted in the figures of 17, 13.11, 12.53 and 10.66 per cent. *In other words, the author demonstrates clearly that these cars of increasing weights, powers and cost represented under the conditions noted, decreasing efficiences.*

The moral is therefore obvious, that "light two motor, single truck equipments were *best* for service under the conditions selected."

This being the case, the heaviest and most powerfully equipped car which cost $5,040 (in comparison with the first, costing the least, $2,710) would prove more efficient on a road where longer trips are made, where there are heavier grades, where greater speed is necessary, where more rapid acceleration is required and where there is finally a denser population.

The most careful study of these circumstances is the determining factor in the selection of car equipments, so that the question of two motor versus four motor cars is to all intents and purposes a question relating to the study of a variety of conditions.

As the author states, "The operating manager is looking not only for an equipment that will fulfill all the requirements of any particular service with the least cost for repairs, and the minimum demand on the power station, but also for one that will combine these advantages at the greatest speed with safety to the public, and the distance to be traveled per trip will allow."

The author recommends a careful consideration of the following items in the determination of the best cars and motors for a certain kind of service:

First—The density of population.

Second—The number of trucks and motors.

Third—The speed in miles per hour.

Fourth—The gear ratio.

The argument he advances is that the *density of the population* must govern the size and seating capacity of the car; also the rate at which stoppages occur, and thus the degree of acceleration required. The speed in miles per hour is necessarily dependent upon this fact and unquestionably the frequency of service as well.

The number of trucks and motors will govern the size and weight of the cars. This is a measure of the tractive effort or draw bar pull, and this again involves the question of acceleration.

The speed per hour is the third point to be considered, particularly with reference to the number of cars in service. An increase in this direction means more power, more of what is called "platform labor" in the car, and, financially speaking, more interest charges to pay because of the increased line expense and power plant equipment.

Not the least important is the *gear ratio* whose influence upon the horse power of the motors, the acceleration, stops per mile, heating, repairs, and finally, station and line requirements, is self-evident.

The last statement of the author with reference to this matter is very interesting as well as concise and simple. He says:

"Too much care cannot be exercised in determining the gear ratio for given service; for there can be no doubt that in many cases lack of power station equipment and excessive motor repairs can be traced to the use of wrong gear ratio. In the first place, cars should be selected of ample capacity for the service requirements, and then motors should be selected with a rating only slightly greater than the service requires, and with a gear ratio so designed that the schedule may be made without resorting to rapid acceleration on starting, and, as a consequence, running the motors on low-efficiency points in order to kill time."

SERIES ALTERNATING ARC LIGHTING.*

BY E. P. WARNER.

During the past three or four years the very extensive introduction of series alternating arc lighting in the United States and Canada for the illumination of streets and public places has called for studious consideration of conditions and results. Valuable experience has been gained and it is gratifying to find that substantial advance has been made in both the reliability and cost of operation. Looking back at the old direct current arc generators of a few years ago, with their very limited capacity and high cost for maintenance, and comparing them with the large direct connected generators of the present day with their high efficiency, practically unlimited capacity, compactness and simplicity, the station engineer, and indeed all financially interested, cannot fail to appreciate that in the series alternating system of arc lighting we have the practical solution of a number of problems. First to build our generators to any desired capacity, second to greatly reduce the floor space required, and third to cut down cost for attendance and repairs.

REQUIREMENTS OF A MODERN SYSTEM.

The conditions which confront the engineers and others, responsible for the welfare of large municipalities, are such as to call for most earnest and careful study, and not the least exacting to meet are those pertaining to the lighting. What system shall we install and how shall we install it, are the questions for which answers must be found. The engineer or station superintendent is called on to consider the different systems and plans of installation from the standpoints of reliability of operation, cost to install and cost to operate. In doing this he is sometimes hampered by local conditions, but as a rule is free to carry out his own ideas and make his own selection of a system.

In many of our larger cities, the lighting systems at present in use, and a number of which have been installed within the last ten years, are so far from filling the demands of economy and certainty of operation that it will not be long before the increased service and reduced cost demanded will bring about their replacement by systems more fully filling all requirements.

In the series alternating arc lighting system of to-day we have a most practical, I may say beautiful, means by which the necessary electrical energy can be supplied to the different sections of a large city. Instead of a large number of small lighting stations scattered about the city, with their attendant nuisance of smoke, noise and dirt, their high cost to maintain and operate and many other objectionable features, we can have large stations located at a considerable distance from the city where land would be comparatively cheap, also condense water and fuel. From this station supply mains at high pressure can be run to any desired number of distributing stations equipped with transformers and regulators. Such a station would be practically noiseless, smokeless and in fact free from nearly all the objections that can be made to the present direct current lighting station. Again, the cost of installation can be brought below that of the small separate stations and the cost to operate very considerably reduced. There is suggested by this system a practical solution of the problem of the smoke nuisance. We may some day have large stations located some distance from the city equipped with smokeless furnaces, from which the city will receive its supply of light, heat and power—then good-bye smoke.

(To be continued.)

Electric Storage Battery Secures New York Central Contract.

The Electric Storage Battery Company of Philadelphia, has been awarded a contract by the New York Central & Hudson River Railroad Company aggregating $900,000, for the equipment of several power houses with electric storage batteries for use in operating the New York Central's trains in and out of New York. Power houses will be built at intervals along the railroad for a distance of 60 miles out of New York, and locomotives will be equipped with electricity to be used as far as Peekskill.

Nine Reasons.

There are said to be nine excellent reasons why the Crosby spring seat valve, manufactured by the Crosby Steam Gauge & Valve Company., Boston, Mass., is the best, because, 1, of its strength, quality and durability; 2, disk seats and valve seats are made of the very best alloy, and from their peculiar construction resist any cutting from the flow of steam; 3, all working parts renewable without removal of valve from the piping; 4, all parts interchangeable; 5, they have a full opening through them; 6, both brass and iron valves are easily and quickly repacked when in use; 7, made only by workmen of the highest skill with special tools; 8, only best materials used; 9, all valves when completed are tested under more than 400 pounds hydraulic pressure to determine the tightness of the seat and strength of the metal. They are guaranteed not to leak at high pressures.

* Paper read at the 13th annual convention of the Northwestern Electrical Association, held at Milwaukee, Wis., Jan. 18-20, 1905.

Hunt "Industrial" Railways.

Few realize the saving made by the use of a narrow-gauge track and suitable cars in handling raw and finished materials. The C. W. Hunt Company of West New Brighton, Staten Island, can furnish figures in this connection that are surprising.

A manufacturer who needs a railway for handling material is immediately confronted by such questions as:

What gauge is best for that purpose? What radius curves should be used? How heavy should the rail be? What style of cars will be best? What kind of cross-ties should be used? How shall the switches and crossings be made? Can turntables be avoided? Can a locomotive be used?

And so on, until it looks as though he would have to abandon his regular business to decide these details.

The Hunt system of railways sold under the trade name "Industrial" answers these questions, and furnishes without trouble, delay or expense, the results arrived at by those who have given the subject careful consideration for many years, both as builders and users of this class of machinery.

The Unit Accumulator.

The National Battery Company of Buffalo, N. Y., is prepared to make new installations complete of electrical machinery, or to make renewals of batteries already installed. The unit accumulator manufactured by this well known concern has been especially designed for high charge and discharge rates, long life and high efficiency.

The unit accumulator positive (Plante) plate is constructed in such a manner that the units, or active portions, are so firmly attached to the rigid frame that they are a part of it, and the full contact between the two exists during the entire life of the plate.

The two sides of the unit are uniform, and the developed surface is sufficient to give high efficiency. In addition to this its mechanical structure is strong, holding the active material closely to it, and allowing free release of the gases.

The National Battery Company has adopted the pasted type (Faure) of negative, and has developed a grid in which the natural molecular shrinkage of the active material has been provided for and taken advantage of, so that the contact is maintained as the shrinkage progresses, owing to the fact that the active material inclosed in the contact portions is drawn more tightly around the grid projections or pins. A negative plate which loses its contact by shrinkage will cease to give its full capacity as this physical change takes place.

Effect of Lubricating Graphite on Engine Cylinders and Bearings.

Satisfactory lubrication depends as much upon the condition of the surfaces as upon the quality of the lubricant itself, and the smoother the bearing surface can be made, the easier it is to lubricate. This point is strongly emphasized when Dixon's Pure Flake Graphite is used in lubrication. When introduced between friction surfaces it soon rubs into the metal, filling every pore and crack and irregularity in the surfaces, coating them with a veneer of great firmness and endurance and of exceeding smoothness.

Cylinders in which graphite has been used take on a wonderful mirror-like polish and valves work quietly and without straining or cutting. Time and again overloaded engines have been able to do all the heavy work demanded of them where graphite has been used in their lubrication when they would otherwise have been stalled. Bearings on which graphite is used never overheat, and overheated bearings are rapidly cooled, and it is a fact proved beyond any question that "seizing" and cutting of friction surfaces cannot take place in the presence of graphite. Therefore in those engine rooms where it is regularly used there will never be any of those costly and perhaps disastrous results of overheated bearings.

Thinner, cheaper oils will suffice for work that formerly required the use of expensive heavy-bodied lubricants, and friction will be lowered with corresponding benefit to the coal pile. Shut-downs and repairs will be fewer and much trouble saved. Graphite lubrication has long since passed the experimental stage and thousands of men are using it regularly with most satisfactory and paying results.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED FEB. 21, 1905.

Electric Railways and Appliances.

782,884. Electric Signaling Apparatus for Railways. Thomas H. Traylor, Denver, Col. Filed Nov. 9, 1904.

782,936. Insulated Step-Joint. George A. Weber, New York City, assignor to the Weber Railway Joint Manufacturing Company, same place. Filed March 13, 1903.

783,027-028. Electric Railway. Joseph Dela Mar, New York City, assignor of one-half to Mathias A. Lazareff, same place. Filed March 8 and June 9, 1904.

783,034. Traction Wheel. Fred A. Gerling, Portland, Ore. Filed June 7, 1904.

783,080. Electric Coupling. Edward F. Ruth, Baltimore, Md., assignor of one-third to Clement H. Warner, same place. Filed June 2, 1903.

783,228. Trolley. Charles J. Sosenheimer, Allegheny, Pa., assignor of one-fourth to William S. X. Taylor, same place. Filed Aug. 11, 1904.

Electrical Machinery and Apparatus.

782,826. Alternating-Current Rectifier. William B. Churcher, Cincinnati, O., assignor to Kenyon Dunham, same place. Filed Sept. 3, 1904.

782,863. Alternating-Current Motor. Robert Lundell, New York City. Filed Jan 11, 1904.

782,887. Rheostat. Hermon L. Van Valkenburg, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed June 6, 1904.

783,001. Reciprocating Electric Engine. Bruno O. Wagner, El Paso, Tex. Filed Sept. 22, 1904.

783,102. Reciprocating Electric Motor. Louis Casper, Chicago, Ill. Filed March 23, 1903.

783,124. Motor-Control System. Maurice Milch, Schenectady, N. Y., assignor to the General Electric Company. Filed Aug. 10, 1904.

783,197. Machine for Insulating Electric Conductors. Charles H. Hawkins, Long Island City, N. Y. Filed Aug. 2, 1904.

783,397. Winding for Dynamo-Electric Machines. Bernard A. Behrend, Norwood, O., and Edwin C. Wright, Newport, Ky., assignors, by mesne assignments, to the Bullock Electric Company. Filed Nov. 6, 1903.

783,398. Dynamo-Electric Machine. Bernard A. Behrend, Norwood, O., assignor, by mesne assignments, to the Bullock Electric Company. Filed Nov. 24, 1903.

Telephones and Telephone Apparatus.

782,828. Measured-Service Telephone-Exchange System. Henry M. Crane, New York City, assignor to the Western Electric Company. Filed Aug. 31, 1903.

782,937-783,340. Telephone-Exchange System. Harry G Webster, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Manufacturing Company. Filed Dec. 3 and 5, 1903.

782,944. Multiparty-Line Locking-Out System. Garrison Babcock, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Manufacturing Company. Filed Nov. 19, 1903.

783,231. Hygienic Telephone-Receiver. Louis Steinberger, New York City. Filed Aug. 15, 1904.

783,283. Telephone-Receiver. William Kaisling, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Manufacturing Company. Filed Feb. 19, 1903.

783,302. Automatic Telephone-Exchange. Nils E. Norstrom, Junction City, Kan., assignor to John Anderson, Salina, and M. E. Richardson, Sterling, Kan. Filed April 10, 1900.

Miscellaneous.

782,816. Electric Fan. Adolph F. Becker, Elizabeth, N. J., assignor to the Diehl Manufacturing Company. Filed April 12, 1904.

782,849. Electric Time-Alarm. Frank Hermance, Union Hill, N. J. Filed July 30, 1904.

782,873. Electric Igniting Plug. George H. Oakes, Arlington Heights, Mass. Filed Dec. 8, 1903.

782,894. Electrolytic Process of Reducing Metallic Sulfids. Charles E. Baker and Arthur W. Burwell Cleveland, O. Filed July 1, 1904.

782,917. Electric Furnace. John M. Morehead, Chicago, Ill., assignor to the Union Carbide Company, same place. Filed Oct. 19, 1903.

783,057. Electric Air-Diffusing Device. Timothy Mahoney, San Francisco, Cal. Filed Nov. 26, 1904.

783,061. Electric-Terminal Clip. David B. Mills, East Orange, N. J. Filed May 3, 1904.

783,141. Thermo-Electric Signal. Martin J. Schick, Bellaire, O. Filed April 21, 1904.

783.174. System of Electrical Control. Eugene R. Carichoff, East Orange, N. J., assignor to the Sprague Electric Company. Filed Aug. 9, 1898.

783,229-230. Locking-Insulator and Insulator-Support. Louis Steinberger, New York City. Filed March 19 and May 11, 1903.

THE TELEPHONE WORLD.

Bell Telephone Company to Issue Bonds.

It has been definitely decided to finance this year's requirements of the American Telephone Company by an issue of $25,000,000 bonds. The bonds will carry 4 per cent. interest.

It is understood that bids will be received from to-day (March 1) and that payments to the American Telephone Company will be at the rate of about $2,000,000 a month.

The bonds will be collateral trust bonds, secured by the deposit of subsidiary company stocks, and will be similar in character to the present outstanding 4s. The present outstanding bonds amount to $28,000,000 and are due in 1929.

Active Campaign for Independent Franchise.

The promoters of the Independent Telephone Company in Council Bluffs, Ia., have begun an active campaign for a franchise and have planned to do considerable canvassing between now and the day of the special election, which is set for March 27.

Attorney F. W. Miller, who has been selected by his fellow promoters to organize the campaign, states that the company does not intend to rely solely on the passage of the franchise ordinance by the mayor's vote, but will shortly file with the mayor the petitions bearing the requisite number of signers, asking him to call a special election. The date named in the petitions is March 27, the same as in the resolution adopted by the city council authorizing the mayor to call such election. The call to be issued by the mayor, Mr. Miller claims, has been prepared, and all that remains is for Mayor Macrae to attach his official signature to it and then for it to be published according to law. The franchise ordinance has to be published with the call and also has to be printed on the ballots. A sum to cover the expense of the special election will be furnished by the Independent promoters.

The Stromberg-Carlson Telephone Manufacturing Company of Rochester, N. Y., reports that it is just completing one of the finest toll boards that it has ever turned out, for the United States Telephone Company of Toledo, O. The board consists of five sections of three operators' positions each, and is equipped with the most modern apparatus.

The Citizens' Telephone Company of Columbus, O., held a stockholders' meeting a few days ago and C. C. Griswold was chosen as a director in place of H. D. Critchfield, who retired from the board. The old officers were re-elected. Frank L. Beam is the general manager of the company.

The Edgerton (Wis) Telephone Company has secured the business of the Bell long-distance line into that city. The wires of the latter company will be connected with the local company's switchboard, and the Bell office discontinued.

The city council of Rushville, Ind., refused a franchise to the Spiceland Co-operative Telephone Company on the ground that the Bell Telephone Company was behind the application.

Independents to Hold District Meetings.

The Ohio Independent Telephone Association, organized last summer at Columbus by all the Independent exchanges in the State, has been subsequently divided into districts, and each district, which is presided over by a vice-president of the parent body, is holding meetings to further the interests of the Independent exchanges, and incidentally present a solid front to the Bell.

The Eighth district of the Ohio Independent Telephone Association, comprising the counties of Williams, Fulton, Lucas, Ottawa, Sandusky, Seneca, Wood, Henry and Defiance, held a recent meeting at which R. E. Hamblin of the Toledo Home Telephone Company, who is a vice-president of the State organization, presided. Representatatives were present from nearly all of the 37 exchanges in the district.

The Whitthorne Telephone Company is one of the latest Independent companies to be established in Carroll County, Tenn., and the new company is in a most prosperous condition. Its lines are now connected with the Mixie Telephone Company, the Beaver Creek Company and the Dixie Company, and its system is being extended to Huntingdon. J. T. Lewelling is president of the Whitthorne Company, and W. E. Robinson is secretary and treasurer. Carroll County is now a perfect network of Independent telephone companies, there being no less than 15 small companies in operation. Several of these lines run into Huntingdon and have good patronage from physicians and others.

George W. Manble, a stockholder in the local telephone company at Fort Scott, Kan., has brought suit in the district court to enjoin the company's officers from transferring its assets to the Bell Telephone Company, which lately bought all but a few shares of the stock. The Bell Company was preparing to consolidate the two concerns. The court is asked to appoint a receiver for the local company.

A long clash between the United Telephone Company and the citizens of Pottsville, Pa., because the corporation raised its rates, was settled last week by the borough council granting a new franchise. Hostilities had advanced to such a stage that the borough authorities went to court with a suit in equity, and the company was directed to remove its poles and wires from the town.

At the annual meeting of the stockholders of the Rural Telephone Company of Hennepin County, Minn., held at Osseo, the company was reported to have 102 patrons, 90 miles of wire and six toll lines. The exchange is in Osseo, and lines run into Corcoran, Hassan, Maple Grove, Brooklyn, Champlin, Rogers and St. Michaels.

At the annual meeting of the stockholders of the New York & New Jersey Telephone Company, held in Brooklyn Friday, the retiring board of directors was re-elected.

The Washtenaw Home Telephone Company of Ann Arbor, Mich., has filed articles of incorporation with a capital stock of $300,000.

Telephone Trust Hearing at Albany.

After a conference between the chairmen of the finance committee and the Assembly committee on ways and means it was decided to hold the first public hearing on the joint resolution for a legislative investigation of the telephone trust on Tuesday, March 7, at 2 P. M.

A number of the farmers of McPherson and Edmunds Counties, S. D., recently organized a telephone company under the name of the Edmunds County Mutual Telephone Company. A. Hoffman of McPherson County was elected president, and F. Blakeman of Edmunds County treasurer. The company controls several rural lines which already are built and will extend the lines during the coming spring and summer.

Residents of Eagleport, O., have become greatly interested in the proposition to build a telephone line from there to Gaysport. A big mass meeting was lately held in the town hall for the purpose of organizing a company to carry out this project. Much enthusiasm was shown at the meeting and it is believed that the enterprise will be a success. It is expected to begin work at once on the new line and it is believed that it will be completed within about six weeks.

One hundred farmers in the lower part of Schuylkill County, Pa., are organizing clubs for the purpose of building Independent telephone lines through their lands to connect with the big trunk lines. Timber is now being cut for the poles.

The Glenville-Inland Telephone Company, operating between Glenville and Inland, Neb., will soon put up more wires. It has lately installed two new switchboards for use in the above towns and will accommodate about 40 subscribers.

The telephone lines erected on the Reading Company's road west of Harrisburg, Pa., to be used in connection with the train service, have been completed and put in operation.

The Glen Telephone Company lately opened its new exchange at Fonda, N. Y.

Telephone Incorporations.

The New York Independent Telephone Company, Albany, N. Y.—to operate in New York City to Boston, Albany, Jersey City, Philadelphia, and other places in the States of New York, Massachusetts, Rhode Island, Connecticut, New Jersey and Pennsylvania, Capital stock, $50,000. Directors: O. S. Lee, Jr., J. M. Woods and B. S. Mantz, New York.

The Healdsburg and Alexander Valley Telephone Company, Healdsburg, Cal. Capital stock, $5,000. Directors and officers: C. F. Matthews, president; W. F. Young, secretary; Thomas Alexander, William McCutcheon and C. C. Hall.

The New Citizens' Telephone Company, Batavia, O. Capital stock, $150,000. Incorporators: B. W. Gilfillan, W. H. Baum, W. F. Fee J. C. Wood, W. G. Jones and G. H. Eveland.

The Worcester Telephone Company, Worcester, N. Y. Capital stock, $1,000. Incorporators: James Nelson, Guy Coats and S. Shafer, all of Worcester.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Albany, N. Y.—The board of directors of the Albany Electric Illuminating Company decided that on and after to-day (March 1) the price of lighting current shall be reduced from 20 cents to 15 cents per kilowatt hour.

Albion, N. Y.—It is reported that a combination of capitalists is being formed to combine the electric light and power plants in this place, Holley, Brockport, Middleport, Lockport and Batavia in one big corporation. J. H. Rollins, superintendent of the plant here, is to be general superintendent, and at present the promoters are connected with the Albion Power Company. It is thought the power will come from Niagara Falls.

Bluffs, Ill.—Fred Brockhouse has secured a franchise for the erection of an electric light plant.

Buffalo, N. Y.—An electric light plant in the new 65th Regiment Armory, to cost $89,000, is proposed. Plans will be prepared by George J. Metzger, architect.

Cairo, Ill.—The city council has set aside $5,000 for an electric light plant.

Colonial Beach, Va.—The city council has granted a 20-year franchise to the Colonial Beach Electric Light & Power Company for an electric light plant and telephone system. Warren S. P. Combs is president and general manager of the company.

Danville, Ky.—The National Construction Company of St. Louis, Mo., has prepared plans for the construction of the new electric light plant to be built here. E. R Vincent, consulting engineer for the town, may be addressed.

Dixon, Ill.—Plans are being prepared by the Lee County Lighting Company for the extensive improvements to be made to its power plant.

Fairbury, Ill.—The Fairbury Electric Light & Power Company has increased its capital from $12,000 to $30,000.

Lena, Ill.—The village board has granted a franchise to Benfer Brothers of Winslow to erect and operate an electric light plant here, and contracted for $1,200 worth of street lamps for a period of ten years.

Litchfield, Ill.—A 75-year franchise has been granted to the Litchfield Electric Light & Gas Company.

Manassas, Va.—The Manassas Illuminating Company, with a capital of $5,000, has been incorporated by W. N. Lipscomb, R. S. Hynson and others to furnish light by electricity for manufacturing plants, etc.

McKinney, Tex.—Jesse Shain, J. D. Bass. and Giles L. McKinney compose the committee which has been formed to install an electric light plant.

Miami, Fla.—W. W. Prout has applied for a franchise to construct and operate an electric lighting and heating plant here.

Millville, Cal.—A proposition to have electric lights in this place is now being considered by several of the local business men.

Oskaloosa, Ia.—The electric light and telephone wires were considerably damaged by a recent $150,000 fire.

Paris, Ill.—The City Gas & Electric Company has increased its capital to $60,000. Improvements are contemplated.

Pass Christian, Miss.—The town council has invited bids for furnishing this place with electric lights.

Sebree, Ky.—It is reported that J. B. Ramsey has secured a franchise to construct and operate an electric light plant.

South Bend, Wash.—The city council has granted to J. M. Etnier a 45-year franchise for furnishing electric power and lights.

Walker, Minn.—The village council has decided to place before the citizens at the general election in March a bonding proposition for the purpose of buying and installing a more powerful electric light plant than that now possessed and which, owing to its inadequacy, has been out of use for some time. It is now proposed to issue bonds to the amount of $4,000, which will furnish a lighting plant for some years to come.

Washington, Pa.—The West End Electric Light, Heat & Power Company of this city has been incorporated with a capital of $25,000 by John Slater, John W. Hallam, Owen Murphy and others.

Wiggins, Miss.—The Wiggins Electric Light Company has been formed with a capital stock of $10,000.

STREET RAILWAYS.

Boston, Mass.—A recent announcement is that an electric railway between this city and Providence, to be operated over a private right of way and at high speed, is to be built. It is the intention of the promoters to use the elevated structure from Forest Hills into this city. It is asserted that stock has been subscribed, surveys made and options on some private land taken and that four groups of promoters have pooled their interests in the plan.

Cleveland, O.—The Electric Railroad Improvement Company has increased its capital from $20,000 to $50,000.

Coshocton, O.—The Zanesville, Coshocton & New Philadelphia Traction Company has been formed to build an electric railway from Zanesville to New Philadelphia. John W. Cassingham, George C. Hay and others are interested. Its capital stock is $10,000.

Ephrata, Pa.—New York and Philadelphia capitalists are said to be interested in a plan to build a trolley line from Norristown to Harrisburg, the first section to be built extending from Norristown to this place, a distance of about 55 miles. Surveyors have been engaged, and they will begin work as soon as the weather will permit. The road when completed would have a total length of 90 miles, and would be the largest continuous trolley line in the country.

Evansville, Ind.—The Evansville & Eastern Traction Company will construct a line from this city to Rockport.

Lebanon, O.—The Miami Transit, Light & Power Company has been incorporated, with a capital of $600,000, to bnild an electric road from here to Xenia. The incorporators are F. C. Richards, M. D. Burke and others.

Marengo, Ill.—The citizens are making an extra effort to obtain an electric road for this place.

Medford, N. J.—There is a rumor here to the effect that William J. Thompson of Gloucester, who owns the new hotel at Harvey Cedars, Ocean County, has under consideration the construction of a trolley line from Gloucester to Manahawkin, through the Burlington County town, for the purpose of booming the seaside resort that he desires to make popular at all seasons of the year.

Morris, Ill.—The Northwestern Traction Company will erect an electric line from here to Yorkville.

Saugatuck, Mich.—The village board will grant a franchise to an electric line.

Valley City, N. D.—E. R. Bradley has asked for a franchise to construct a trolley line in this city.

Washington, Ia.—This city has voted to grant a franchise to the Iowa City, Kalona & Washington Electric Interurban Railway Company.

Wheatland, N. D.—An electric line will be erected between Fargo and this place.

POWER PLANTS.

Dayton, O.—The Dayton Malleable Iron Works will expend $40,000 in improvements. A new power plant is to be built.

Keokuk, Ia.—A project is on foot to dam the Mississippi River, between this city and Hamilton, Ill., for power purposes. If the project for which this dam will form the basis is carried out, it will result in the construction of the largest power plant in the world. The largest plant at Niagara will develop 50,000 hp. The plant under contemplation here is planned to develop not less than 60,000 hp., which will be available for the surrounding towns for a radius of 60 miles. It will call for an investment of not less than $6,000,000 and will be built entirely without cost to the Government.

Pittston, Pa.—The Erie Coal Company will build a large electric power plant on the outskirts of this city for the purpose of operating its collieries with electricity.

Port Clinton, O.—Negotiations have been closed for the electrical equipment for the new Toledo, Port Clinton and Lakeside permanent power plant to be located here or at Oak Harbor.

BIDS WANTED.

Clarinda, Ia.—The Lee Electric Light Company is in the market for the following equipment: One 100 hp. high pressure return tubular boiler, one simple or compound Corliss engine for direct connection to a two-phase alternator and one 100 or 150 kw. two-phase, 60-cycle, 2,000-volt alternator.

Graham, N. C.—Bids will be received for the construction of waterworks and electric light and ice plant for this city. H. A. Pressy, engineer, 1416 F street, N.E., Washington, D. C.

Jacksonville, Fla.—The Florida Dental Supply Company of this city wants prices from dealers on small motors and dynamos.

Muncy, Pa.—Sprout, Waldron & Co. of this place want a new or second-hand 2 hp. electric motor in good condition.

Richmond, Va.—The Cardwell Machine Company, 1900 East Carry street, this city, is in the market for 15 to 25 and 30 hp. vertical engines and boilers, mounted on one base; engines to be plain slide valve of suitable size cylinders to give above running powers running at norma speed.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 15⅛@15¼c.; Lake 15¼@15⅜c.; casting, 14⅞@15c.

Earnings of the Philadelphia Electric for the month of February are reported at $50,000 more than for the same month in 1904.

According to Chicago dispatches, the North Shore Electric Company has increased its capital stock from $1,250,000 to $2,000,000.

The Mexican Telephone & Telegraph Company has filed a certificate of organization at Portland, Me., to conduct electrical plants; capital $10,000.

The Detroit United Railway Company has applied to the New York Stock Exchange to list $4,257,000 first consolidated mortgage 2½ per cent. gold bonds of 1932.

The Milwaukee Heat, Light & Traction Company, a subsidiary of the North American Company, has increased its capital stock from $500,000 to $1,000,000.

The Massachusetts Railroad Commissioners have set March 2 as the time for hearing the petition of the Boston Elevated Railway Company to issue $7,500,000 bonds.

The franchise of the Vandergrift Construction Company of Philadelphia to build a $3,000,000 electric road from San Juan to Ponce, Porto Rico, has been revoked by the executive council.

Based on the present volume of output and the known factory cost, it is estimated by General Electric people that the net profits of the company are running at about $1,000,000 a month.

President Winter of the Brooklyn Rapid Transit Company has announced that $2,500,000 would be spent at once by that corporation to provide additional equipment for elevated and surface lines.

It is understood that plans have been made for refinancing the United Electric Railway Company of Baltimore and that an assessment will be made on the common stock of the company.

The Montgomery (Ala.) Traction Company has been placed in the hands of a receiver on petition of the North American Traction Company of New York, in default of the payment of the interest on $400,000.

Plans for the erection of a large new power house for the Chicago City Railway Company, to cost $5,000,000 to $6,000,000, are being prepared. Electricity will be supplied from this power house for all lines of the system, according to present plans.

The Missouri Central Railroad Company, capital $4,000,000, is soon to increase its capital to $12,000,000. St Louis financiers are promoting it for the construction of an electric railroad from St. Louis to Kansas City. An air line is promised within two years.

It is announced that the controlling interest of the International Traction Company of Buffalo, N. Y., which was held by Cuyler, Morgan & Co. and J. P. Morgan & Co., has been sold to Henry J. Pierce and his associates of Buffalo. It is understood that Mr. Pierce, who is president of the Buffalo Chamber of Commerce, will succeed W. Caryl Ely as president of the company. The company has a capital of $15,000,000, of which $5,000,000 is 4 per cent. cumulative preferred and $10,000,000 common stock.

EDITORIAL NOTES.

The London Telephone Monopoly.

While a fight is being waged in this vicinity against the New York Telephone Company, a somewhat similar struggle has been going on in England against the National Telephone Company. In the latter case, however, the unpleasantness arose not so much through high rates as on account of inferior service, due, it is claimed, to antiquated methods and apparatus.

As with the American Bell Telephone Company, the National Telephone Company in England in the earlier days got a monopoly into its own hands by buying out a number of smaller companies in the provinces. The Postmaster-General took steps, in response to public clamor, for weakening the grip of the company, by a large expenditure on trunk line communications and the provision of additional exchanges and services to be worked by the postoffice, to compete with the National Company in the London area. Municipalities also, a short time ago, embarked upon telephone schemes of their own, but their systems, where carried out, have been subjected to severe criticism from telephone experts and they have had to fight a rate-cutting competition against the National, which, having big reserve funds, could cut rates regardless of the loss which might arise in one or two places, with a view to defeating the competition. The licenses of the National Company and of the municipal corporations all expire in 1911, and as there is thus only a period of six or seven years to run, and municipalization has not been successful, much uncertainty has been felt as to what really was the best policy to give that impetus to telephonic progress that has been so long wanting in England. The position resulting from the uncertainty has been an indisposition on the part of the National Company to extend its system both in London and the provincial cities, involving heavy capital expenditure, until there was something more definite known as to its treatment by the Government when the licenses expire. The postoffice, also, has been seeming to leave new work in London very much to the company, because other claims on the Government funds stood in the way of big grants for telephonic schemes. So, between the two, the would-be user of the telephone has been deprived of the full privileges which up-to-date cities have long possessed.

This state of affairs is now practically at an end. On February 2 an agreement was made between the Postmaster-General and the National Telephone Company—subject of course to the ratification of Parliament—under which it is arranged that the existing dual arrangement over the whole of the United Kingdom is to terminate on December 31, 1911, and the lines will thenceforth be the property of the Postmaster-General. With the actual terms as to purchase we need not deal, except to say that there will be practically no payment made to the company for good will or in respect of profits, and the money will be paid by way of annuity for a term not exceeding twenty years; but the company is now assured, under this agreement, that any capital expended during the next six or seven years upon the needed extension of telephonic facilities, will not be sacrificed by it when the purchase-time arrives.

No doubt there will be many criticisms offered in regard to certain details, and some doubt is expressed as to the desirability of the system remaining in the hands of the company even until 1911; while yet others contend that the system ought not to be nationalized. But leaving aside these criticisms, the approving of the agreement will clear out of the way all uncertainty which has blocked progress during the past few years, and a big capital expenditure upon extensions to exchanges and lines, and big outlay upon all telephonic apparatus will result.

* * *

The Electrical Mysteries of the Sun.

We have held, since Helmholtz enunciated the fundamental law of the conservation of energy, that electricity is but the equivalent of some force, by whose transformation merely another phase of its existence is manifested.

This idea has been exploited for many years, and of late another presumption has followed closely on its heels—that electricity and matter are mutually identifiable. Interesting as these conclusions seem, wonders of a more fascinating nature pour down upon us from the sky, launched toward the earth with inconceivable speed from the sun. The sun sends us heat, but it also yields its myriads of electric corpuscles, which set the aurora blazing with ghostly gleams in the north and south and sends vast eddies of electricity around the earth with their fluctuating magnetic fields.

It is well to know that the sun's mass is 1,000,000 times greater than that of the earth; that a large orange and a small pin head separated from each other by several feet of space, are a duplicate of the astronomic proportions; that the convulsions and storms raging on this gigantic sphere find their echo in the far off regions of all surrounding planets, in whom, as in our own little world, electric and magnetic forces are induced to action.

It is not so many years ago that a paper was read by Prof. Pupin of Columbia University, and reinforced by experiments, in which the electrical origin of the sun's corona was demonstrated to a degree which to-day seems almost prophetic. Photographs of the natural and artificial coronæ when placed side by side seemed to have been obtained under the same conditions. It is the corona which seems to present and to contain one of the greatest of solar mysteries.

It may seem futile to spend time in speculation as to its cause or nature, but this is more than excusable in view of the inherently electrical character of this colossal phenomenon. Colossal it will be admitted to be, when the fact that coronal streamers have been measured and found to exceed 250,000 miles in length. The extreme tenuity, lambent brilliancy and unrecognizable spectroscopic character have stamped this mysterious crown of the sun as an essentially non-chemical manifestation. Thus, a new field of investigation has been opened up in this direction, supported on the one hand by purely terrestrial and in all probability, secondary evidence, and on the other hand by solar exhibitions of a primary nature that seem to originate from purely electrical causes. The latest exhibition of this kind is in the way of sun spots, which are known to appear periodically every eleven years, and give rise on the earth at such times to the well known magnetic storms, auroral lights and earth currents. We have already advanced the point brought forward by Marconi, that at night he could signal further than during the day, the sunlight seeming to interfere with the waves he projected, the cause probably being not the sunlight, but the electrons striking the earth on the bright side. This might be regarded by some as an accumulation of evidence of a most convincing nature, but the unfortunate fact remains that it has not as yet been properly correlated. It is generally admitted that the 92,000,000 miles of space between earth and sun form not so much a gap, as a link; and the ether bridge is traversed by a variety of forces, among which are certain forms of waves of which we are only now becoming conscious. Mysteries they may be to-day, but we have the hope that the newer knowledge that has and is coming, will enable us to arrange these facts in such a manner that they will present another well written page in the great book of nature.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

Tuesday morning at 4 o'clock the 5,000 employes of the Subway and elevated roads of Manhattan were ordered to go on strike. It is the culmination of a dispute that began with the opening of the Subway. As we go to press—seven hours after the strike was ordered—a few trains have been run on the roads effected. There are rumors of strikes on the surface lines of New York City and Brooklyn.

The Electric Bond & Share Company of Schenectady, which was incorporated at Albany last week with an authorized capital of $4,000,000, is controlled by the General Electric Company. While it is understood that the new company has no definite projects in view at the present time, its object is to investigate new electrical projects of all kinds, and if it seems advisable, to take them up. By its charter it is empowered to construct roads, tramways, railways, and hydraulic, electric and gas plants. Whatever electric supplies it will need for such work as it undertakes will, of course, be obtained from the General Electric Company.

The figures given in the new edition of Garcke's "Manual of Electrical Undertakings" are of interest in proving, says our London namesake, how rapid is the increase in the capital invested in electrical schemes. Thus we find that in 1896 the total amount then invested represented $305,000,000, to-day it is close on $1,335,000,000. In electric lighting an average return is made of 5.03 per cent. upon a capital of $120,000,000, while in electric traction the corresponding figure is 4.33 per cent. on a capital of $305,000,000. What will be the relative importance in, say, a dozen years from the present time of the electrical, compared with other national industries, few of us are bold enough to foretell.

MODERN OVERHEAD TRANSMISSION LINES.[*]

BY G. SEMENZA.

The problem of the construction of an overhead power transmission line can be stated in exact engineering terms as follows: To support on insulators a certain number of wires so as to obtain the necessary stability of the installation with the minimum cost in capital and yearly maintenance. The construction of the transmission line demands a careful study of the topography of the track, the permissible dip of the wires, their tensions, and lastly, the strength of the supports. The forces acting on the various parts of a line are its weight, the wind pressure on wires and poles, and the weight of snow and ice it may have to carry. When the diameter and coefficient of elasticity of the wire are known, it is easy to determine the form of the catenary from the two extreme conditions—first, when under maximum stress due to weight of snow and wind pressure at the lowest winter temperature, and second, when at the highest summer temperature. The first condition gives the maximum possible tension of the wire, and the second the greatest dip of the catenary. From the latter figure, the height of the points of suspension can be determined, so that the middle point of the catenary may be never less than a safe distance above the surface of the ground.

When the track is a straight line with equal spans, the longitudinal tensions on any support balance each other, and they have then only to resist the weight of the wire and the wind pressure. For corner posts, the two tensions give an unbalanced resultant in their own plane, and further, when two spans are unequal, there is an unbalanced longitudinal tension. Thus it it easily possible to calculate the vertical and horizontal tensions which each wire transmits to the support, and, knowing the height of the wires, all the elements are to hand for the design of the supports and the foundations. The wind pressure on the post itself is small enough to be neglected.

Assuming that the amount of copper in the line has been determined from Kelvin's law of maximum economy, the following are the chief points in the erection of the line that demand attention. First of all, there is the choice of the route, and it is at once obvious that, if possible, this ought to be a straight line. For one reason, with the same percentage drop, the section of copper varies as the square of the length of the line, and if it is set out in a curve necessitating a 20 per cent. increase in length over the distance "as the crow flies," the weight of copper would be increased by 44 per cent. Then, instead of plain light poles, heavy angle supports would be necessary, and these not only represent a greater capital expense, but constitute points of weakness, as the insulators and members of the built-up post would be subjected to much higher stresses. It will always pay then, even when expropriation and way-leaves cost considerably more, to select a straight-line route.

The arrangement of lines on the supports is controlled by electrical and mechanical considerations, as the possible contacts between adjoining wires when subjected to oscillations caused by wind must be guarded against. With continuous current, the matter is quite simple, as there are no electromagnetic restrictions on the distance apart of the wires or their arrangement, and for this reason very high pressures may be used without any precautions except giving plenty of clearance. With polyphase currents, on the other hand, there must be a symmetrical arrangement of the conductors, and a compromise must be made between the mechanical and electrical exigencies. For three-phase lines, the figure of symmetry is an equilateral triangle, but it may be disposed in space in various ways; for instance, with one side vertical or one side horizontal. Although, electrically, they are equivalent, there is a marked difference in the mechanical result between the two methods, as is shown in Fig. 1 (A and B). This illustrates a section taken at the middle of the span, and the projections of the three catenaries on a vertical plane. The dimensions are in millimeters. Only the wires and insulators are shown in the diagram, the poles being omitted. With the action of the wind the wires will oscillate so that the lowest points will describe circles having as centers the projections of the supporting insulators. It will be easily seen from observation that the arc of the circle through which the wires have to travel in case A for neighboring wires to come in contact is much smaller than in B. The maximum angle through which the plane of the catenary can be displaced is terminable in each case, and in the arrangement B much larger dips, and therefore much larger spans, can be used with impunity than in A, and thus it is in every way superior.

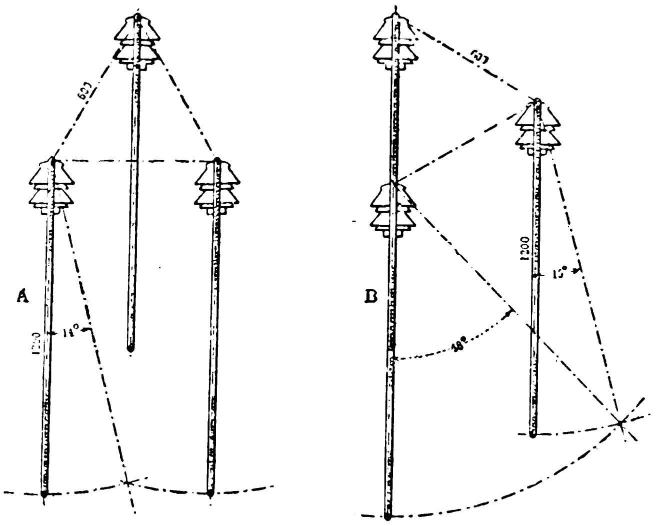

FIG. 1.

In considering wind pressure, the maximum is taken to be 280 kg. per square meter and the effective surface of the wire as its length multiplied by half the diameter. Recent experiments have shown, however, that this formula gives too high a result; but one more nearly in accord with the observed values is obtained by using the empirical formula $P = 3.10^{-5}dv^2$, where d is the dimeter in centimeters and v the wind velocity in meters per second, and P is given in kilogrammes per centimeter length. Where double lines are employed, as is usually necessary in important schemes to diminish risk of breakdowns and facilitate repairs, care must be taken to avoid having two wires in the same horizontal plane as they might touch when oscillating under heavy wind pressure (Fig. 2).

The length of the spans is not, however, controlled alone by the nearness to which the wires may approach under wind pressure. It is a very common argument to say that when the line is subjected to great stresses, due to snow or wind, long spans are inadvisable, but this is hardly true, as by using a sufficient dip the limit of elasticity of the copper need not be exceeded. By increasing the spans the number of insulators is diminished. However well the insulators may be designed they are the real points of weakness in the line, as should even one out of 10,000 break it may give rise to considerable damage.

---

[*] Paper read before the Associazione Elettrotecnica Italiana. Abridged translation by John R. Dick in "Electrician," London.

The economic aspect of the problem can be realized by remembering that the increase of span diminishes the number of supports but increases their height and the stresses to which they are subjected, and therefore their weight. The most suitable span is, therefore, the one which requires the smallest weight of material per mile, and it can be only ascertained by successive approximations. Long spans, besides improving the line electrically, require less expense for expropriation or wayleaves as these costs are usually proportional to the number of supports:

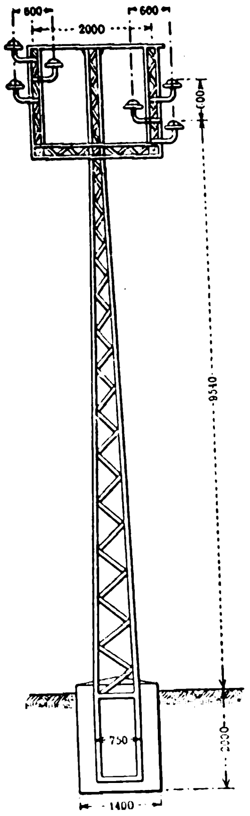

FIG. 2.—SUPPORT FOR DOUBLE LINE.

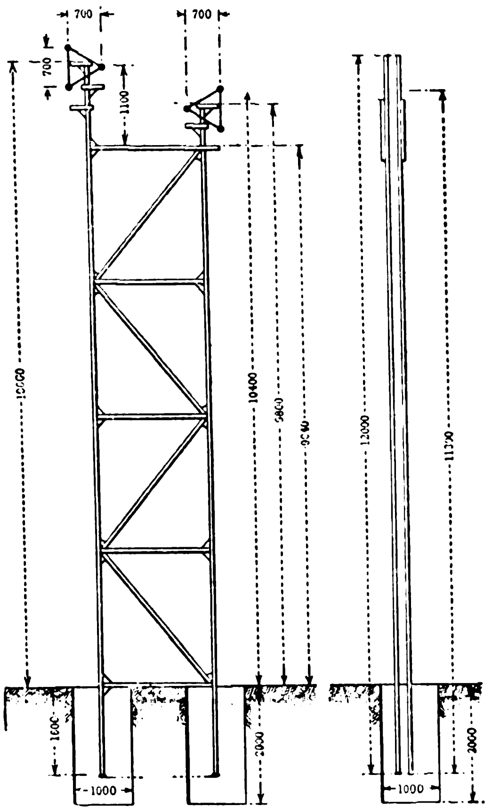

FIG. 3.—ELASTIC IRON POSTS CARRYING DOUBLE LINE.

The materials employed in the construction of the posts are wood, iron, and, to a small degree, reinforced concrete. Iron permits of long spans, because it can be readily designed to take the resulting stresses. It is, however, necessary in such cases to provide a specially heavy foundation. An economic consideration which renders iron preferable is that, as it is more durable, its depreciation may be allowed for on a 30 years' basis, whereas with wood the period is not more than eight or ten years. The annual cost of maintenance of iron poles—being only that of painting—is considerably less than for wood. Regarding the increase of insulation said to be due to a wooden pole, this is quite unimportant, and in rainy weather is not more than one-ten-thousandths that of the insulator. Although with the use of iron a short-circuit is almost certain when an insulator breaks, there is with wooden poles the peculiar phenomenon of slow combustion of the wood without the insulator being actually perforated. Mixed supports of iron and of wood partake of all the defects of the latter, such as the absence of sufficient strength and the difficulty of making a permanent joint to the iron base on account of the wood warping.

The original designs of metallic supports were excessively heavy as the calculations were made on the hypothesis of all the wires on one side breaking, but experience proves that this condition is almost impossible to occur. Any cause sufficient to break the whole bunch of wires would certainly overturn the post itself. The calculation was also based on the supposition that the post was perfectly rigid so that the breaking of all the wires on one side permitted the full unbalanced horizontal tension to come on the post, but this is found not to be the case, as the post instantly deflects and reduces the tension of the wires. If this is borne in mind, and if, also, the simultaneous breaking of only two wires on one side is allowed for, then the weight can be greatly reduced. The posts of the present Paderno transmission line with 60 meters spans were actually calculated on this basis.

Quite recently a very great improvement has been introduced in the construction of metallic supports by making them elastic. The first instance of this was in the transmission line of the Brembo scheme. The idea of this design originated from the following considerations: In a straight track and with equal spans the only force acting on the supports apart from the weight of the wire is the transverse wind pressure. It is, therefore, unnecessary to make them withstand a longitudinal stress, and they need only be designed for a transverse stress. As is seen from Fig. 3, they consist of two parallel uprights of channel iron about 2 meters apart, trussed together with angle irons. Should the wires ever get broken the supports by their elasticity will bend in the longitudinal direction, and this deflection will instantly diminish the tension. In the highly improbable case of the breakage of all the wires in one span, it is found that the first support beyond the break will deflect considerably, but as this deflection diminishes the length of each successive span, and, therefore, the tension of the wires, the second support will be deflected but to a lesser extent. The further supports will also deflect, but always to a lesser degree, and by calculation it is found that should the tension be entirely removed from one side the resulting stress would not exceed half that on a rigid support. Thus we arrive at the apparent paradox that the weakness of the support is a factor of its resistance to breaking.

Regarding the relative cost of making the line with wood or iron supports, it must be borne in mind that the comparatively small number of the latter compensates for the greater cost and the heavier foundations. Thus a line carrying six wires of 8 mm. diameter each would only cost $1,080 per mile, with elastic iron posts 15 to the mile, as against $1,005 for wooden poles 57 to the mile. With the longer life of the former the annual amount for depreciation would be very much smaller; thus the construction is really cheaper.

With reference to the general argument, it will be apparent that too much importance cannot be attached to the choice of insulators. It is a great and unjustifiable error to select those on the basis of price alone. The value of the insulators is not a great item in the total cost of the line, and a shilling more spent on each one will give an enormously increased safety in working.

ELECTRICITY LEAFLETS.

BY NEWTON HARRISON, E. E.

THE MOTOR.

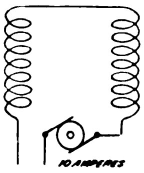
Kinds of Motors.—The motor is divided up into classes according to its winding and the character of the current employed for its operation. The direct current is used for motors wound as follows:

Constant current series wound motors.

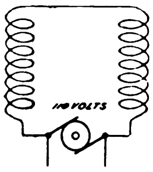
Constant potential shunt wound motors.

Constant potential differentially wound motors.

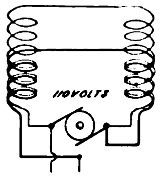
Each of these types is distinct, as far as its winding is concerned, although the last is a combination of the first two, that is, shunt and series winding. Series wound motors are employed on direct current circuits which supply constant current and constant potential. Both high tension arc light constant current systems make use of them and street railway 500-volt constant potential systems. The shunt wound motor is used for stationary work, such as the running of machine shops, printing presses, etc. It is of course possible to install series motors as well, in the places mentioned, but then there is present the ever attendant risk of high potential circuits. The system, therefore, best suited to a city's needs is a low and constant potential system, such as is found at present installed in New York. This statement is made with reference to the distribution of current; as it is now established that electric light and power systems representing work conducted on a very large scale when analyzed will be found to consist of three departments:



SERIES WOUND MOTOR
CONSTANT CURRENT



SHUNT WOUND
CONSTANT POTENTIAL



DIFFERENTIAL WINDING
CONSTANT POTENTIAL

Generation of the current.

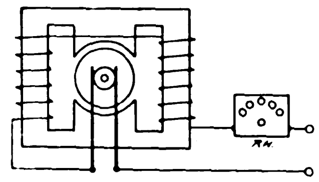
Transmission of the current.

Distribution of the current.

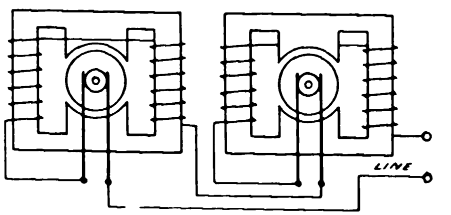
Speed of Motors.—The question of speed is a very important one in connection with motor design and construction. The two possibilities open in this direction are *constant* speed and *variable* speed. As speed in a motor is controlled by the parts which give rise to it, namely, the armature and field; and as the power of these is dependent upon the current in the armature and the strength of the field, it is evident that the question of speed is largely solved along these lines. Speed in a motor can be controlled and varied by placing a resistance in series with it and thus controlling the volts and amperes it receives; but automatic control is perhaps better represented in such cases when a constant speed is desired by differential winding. The ordinary type of shunt wound motor possesses a fairly constant speed when the load is increased or diminished, whereas the series wound motor will increase in speed as the load is reduced and decrease in speed as the load is increased. A differentially wound motor, as its name implies, is one constructed with a differential field, that is to say, a field whose magnetic strength is increased or diminished, not with the increase of the load, but reversely. In a motor of this type of winding its field is weakest when its load is greatest and its field is strongest when its load is least. Thus it seems that the question of speed is largely dependent upon the relationship between the load of a motor, its strength of field and the impressed EMF. supplied to it. Changes in these will mean changes in the speed, and by such means, it may be said, the purpose of a motor is outlined, whether for constant speed or variable speed, with a constant load or a variable load.

The Series Wound Motor in Service.—To understand the service for which a series wound motor is best suited, it is necessary to understand the influence upon it of more or less volts, more or less current and a heavier or a lighter load. To begin with, the very nature of a series winding calls for the same current in both armature and field. This fact is emphasized in order to show how responsive the motor is to such changes as may occur in the back EMF. of its armature. The current which passes through a motor may be determined by the formula:

$$\text{Current} = (\text{impressed EMF.} - \text{back EMF.}) \div \text{resistance or amperes} = \frac{\text{volts of line} - \text{back EMF.}}{\text{resistance in ohms.}}$$



Series Motor with Resistance



Two Series Motors in Series

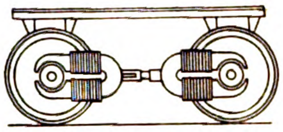
Supposing a series motor has a resistance through armature and field of 2 ohms, and its armature develops a back EMF. of 400 volts; then if the impressed or line pressure is 500 volts the current will be:

$$\text{amperes} = \frac{500 - 400}{2} = 50.$$

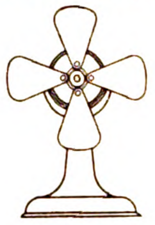
Examination of this formula will show that if the resistance is increased the amperes will diminish; also that an increase in the back EMF. will reduce the current. It will show in addition that if the volts supplied to the motor are increased, more amperes will flow; there will therefore be more torque or pull to the armature and in consequence a higher speed. Increasing the pull of an armature by increasing the impressed pressure, by reducing the resistance, or by reducing its back EMF. are clearly shown in the formula by the increase of the amperes which would thus result. Manipulation of the field strength is the means employed for affecting the back EMF.; in this case if the field is cut down either by shunting the field winding or by short-circuiting part of the lines of force, less lines of force are cut by the armature conductors and a lower back EMF. is produced. More current cannot pass in if the machine is series wound and fully loaded on a constant current circuit. Therefore under such conditions with a weakened field its pull would be reduced and its speed slackened. A series motor increases in speed as its load is reduced and diminishes in speed as the load is increased. A reduction of the load causes the then present pull of the motor to increase its speed; this also increases its back EMF. and consequently reduces the current in both armature and field. Although there is now a weaker field due to fewer ampere turns on the field magnets there is a higher speed. A still further reduction of the load will increase the speed still further until if the motor is entirely without load it will run fast enough to destroy itself.

In street railway service the series motor is used exclusively, and its regulation in regard to speed and power is carried on by a controller which throws the motor circuits from being in series with each other eventually into multiple, it being understood that more than one motor per car is in operation at a time. A series motor with a resistance box in series with it, represents in many respects the method of controlling a street car motor, only instead of a resistance of this character, its place is taken by another series motor. And thus the two series motors in series, and if necessary, with a resistance in series as well, is the present basis for street car control. Either a resistance, or another motor in series, is a means of reducing the pressure and current supplied, which is theoretically and fortunately practically a successful method of governing the speed.

From this standpoint, the motorman is merely manipulating the circuits of the series motors, so that more or less current and pressure is allowed to affect each motor individually, for the purpose of giving the car a greater or less speed. It has been stated that a series motor running idle, that is, without a load, will tear itself to pieces. In street car service, even though the car is empty, the motor has the work to do of carrying the car trucks and car body, and therefore cannot develop an abnormally high speed. But it will be readily noticed how much faster an empty car travels, than one filled with passengers. The motors in this case are taking all they possibly can in the way of current at the pressure of the line. More pressure would mean an increased speed or a more powerful field, but the limited pressure of the trolley system, 500 volts, forbids this, and the only remedy for heavily loaded cars is more powerful motors.



Constant Load on Street Railway Series Motor.



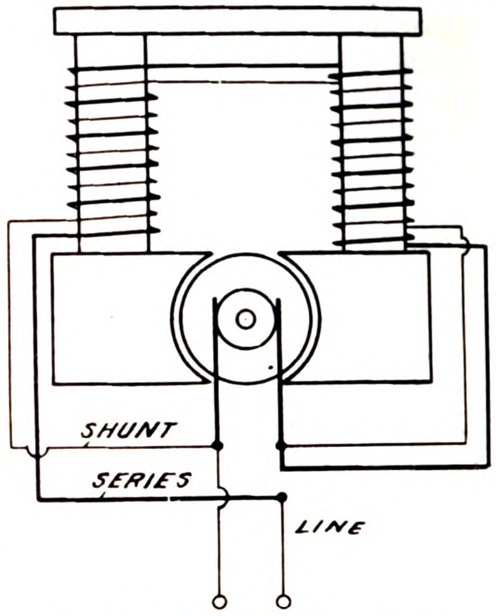
Constant Load on Series Fan Motor.

Series Wound Fan Motors.—Fan motors are series wound as a rule, unless they are to serve a different purpose from that of only running fans. A series wound motor must always be doing work when in operation, and the presence of a fan therefore represents a load which enables it to comply with the requirements of practice. Different speeds are obtained by means of a switch which governs resistance in series with the motor. At the two or three points indicated the switch allows a current of greater strength and pressure to enter which, with with the fan load permanent, permits of a higher speed. A series wound motor for the driving of sewing machines or light loads, could not be used unless there was a certainty of the load never being removed; otherwise the armature of the motor would fly apart. This form of service calls for a motor which can meet conditions of full load or no load without such an abnormal development of speed.

The Shunt Wound Motor.—The shunt wound motor is one in which the speed is fairly well preserved under all changes of load. The field winding receives its current in multiple from the line, and therefore is not affected by the changes in speed or load. The back EMF. of the armature is the regulator of the amount of current the motor takes and this in its place is determined by the amount of work the motor is doing and its effect upon its speed. As the load is increased or diminished on a shunt wound motor, the speed is affected accordingly. The back EMF. will rise or fall, which will be the means of allowing a current to flow through the armature proportional to the effective EMF. The automatic action of the back EMF. in this respect has made the shunt motor peculiarly noteworthy. Under these circumstances, it is easy to increase the speed of the motor by means of the field.

If the field of a shunt motor is weakened, the back EMF. of the armature would either drop, or (on account of the increased current which would thereby result, and necessarily the greater torque in the armature), the speed would increase. This in practice is found to be the case. That is to say, if a resistance is put in series with the field winding of a shunt motor, the speed of the motor will either increase or decrease as the current in the field winding is decreased or increased. A very interesting experiment, which carries out this idea in practice is that of running a shunt motor idle and suddenly cutting out the field winding. The effect of this, tried with a small motor, is to raise the speed to a very high point. The motor is not entirely without a field in this case, but depends upon the residual magnetism and armature reaction for such as exists. The back EMF. thus suddenly cut down, causes a powerful current to flow through the armature. The effect of this is a greatly increased torque and a higher speed, until if the motor can stand the strain it reaches a speed at which there is some approximation between the back and impressed EMF. to that existing under normal conditions. Advantage of this fact is taken in the regulation of shunt motors by the so called differential method. By this method the field is weakened when the speed slackens, as shown by the idea involved in the differentially wound motor.

Differentially Wound Motor.—The differential field is obtained by means of two field windings—one a shunt winding and the other a series winding. The shunt winding receives its current and pressure as usual from the main line, but the series winding takes the entire current of the motor. This winding is so arranged, that as the current required by the motor increases, its *demagnetizing* effect upon the field also increases. It is really a compound wound dynamo turned into a motor. Thus, increasing load means a tendency to increasing speed; which compensates for the number of turns per minute lost through the increased load. When the motor runs idle, the current in these series turns has little or no effect on the speed. In fact the motor is now a simple shunt wound machine. The disadvantage, however, lies in the reduction of the field strength when it is most needed to do the heavy work required. A uniform speed is secured by this means, within certain limits, for all changes of load.



Windings of Differentially Wound Motor.

WIRING A STEREOPTICON.

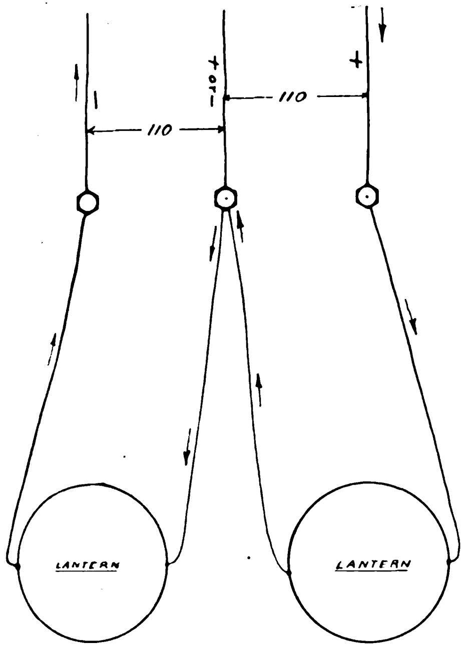
BY W. H. WAKEMAN.

Stereopticons are so extensively used at the present time, and the electric current is so often available for this purpose, giving a powerful and steady light, that suggestions concerning necessary wiring are of interest and value.

The lanterns are sometimes placed side by side, but in other cases one is located above the other. The wiring is alike practically, but the former system is illustrated for convenience.

Fig. 1 illustrates a three-wire system with 220 volts potential between the outside wires, which is "split" (according to the lineman's vernacular), giving 110 volts between each pair, as shown.

The current operates the same as if each lantern was a large incandescent lamp, for coming out over the positive wire it goes to the upper carbon, thence to the lower, giving out its bright rays as it leaps the intervening space, and if only one lantern is is operation (as when the apparatus is being started for a lecture) it goes back over the central wire. When the second lantern is connected, current flows as shown by arrows, for after lighting the right hand one it goes to the central binding post, then turns and goes to the left hand lantern, after which it returns over the negative wire. This assumes that the resistance offered by each lantern is exactly equal to that of the other. If not, the central wire either brings out or carries back enough to take care of the difference, according to which is required, therefore it is called the positive or negative wire, according to conditions.



220 VOLT THREE WIRE SYSTEM

Fig. 1.

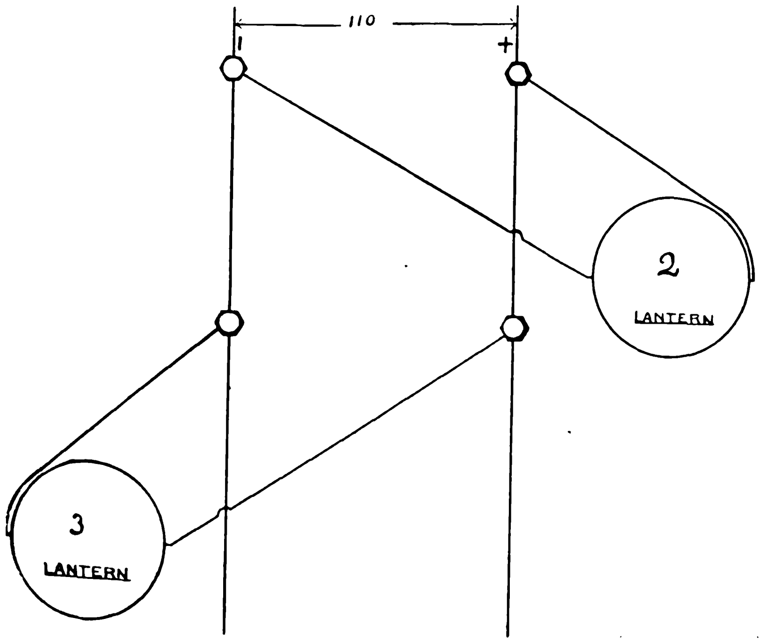


Fig. 2.—110-volt Two-wire System.

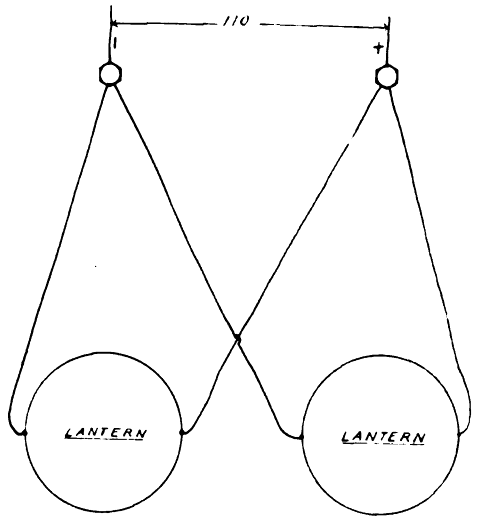
A resistance box or coil must be connected in series with each lantern, or, in other words, it must be connected so that current will pass through one, then the other. It makes but little difference whether this is located on one side or the other of a lantern, but it seems more natural to place it in the positive line. Locating it in the negative line seems like regulating the speed of a steam pump by partially closing a valve in the exhaust pipe, leaving the throttle valve wide open.

These resistance boxes are usually fitted with three binding posts. With a 220 volt current "split" as mentioned, use the two outside posts, but if it is a 110-volt current "split" making the available potential 55 volts, use the central binding post instead of one outside post.

While it is perfectly plain to everybody who understands the rudiments of electric light service, that a single lantern designed for 110 volts potential can be used on a regular 110-volt circuit without trouble, it is not so plain to all that a stereopticon in which both lanterns must have 110 volts can be used on a regular 110-volt circuit, as it is perfectly natural to think that it requires 220 volts.

At 2 in Fig. 2 we have a 110-volt single lantern on a 110-volt circuit. Going on further we find another single lantern at 3 and they are connected in parallel. Why should they not be connected as shown in Fig. 3, where both are equal? Certainly there is nothing either in theory or practice to prevent it, yet I have been told that it cannot be done, and not by an amateur either.

If a 110-volt circuit is available and a stereopticon adapted to 55 volts is to be used the lanterns may be connected in series as shown in Fig. 4. Under these conditions one will not light until the other is also ready, when both will shine together. A disadvantage of this plan is that if anything happens to one, the other will go out too, thus leaving the operator in trouble, whereas if they are connected in parallel or multiple, failure of one does not affect the other. While this would spoil the dissolving effect produced by two lanterns properly adjusted, it does not prevent the lecturer from finishing his entertainment, although the pictures appear at a slight disadvantage.



110 VOLT TWO WIRE SYSTEM

Fig. 3.

Sometimes we attend a lecture and find that the stereopticon is not operated to the best possible advantage. This may be due to the fact that the operator appeared on the scene 15 minutes before the lecture began, assuming that everything was ready for him when it was not.

Such a plan will answer very well for places where a stereopticon remains in one place for a long time, such as in a lodge room, where it is always used in routine work, provided it is cared for exclusively by one man. The writer has been engaged in this work for several years, thus learning something about it. There is no chance to try a stereopticon before it is wanted in such a place, as the room is in use for other purposes. When the pictures are wanted they must appear at once, and be right too.

Of course practice makes perfect here as elsewhere, therefore even when new carbons are required they are put in and the stereopticon used at once without previous trial. The arc must be accurately centered in order to secure good

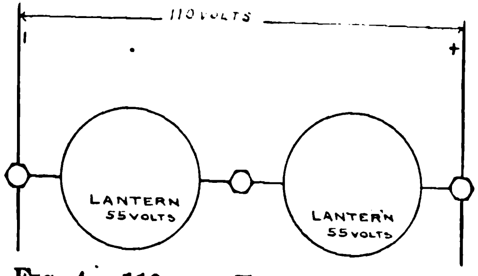


Fig. 4.—110-volt Two-wire System.

results, so that a system of measurements must be adopted which will enable the operator to fix his light at a given height.

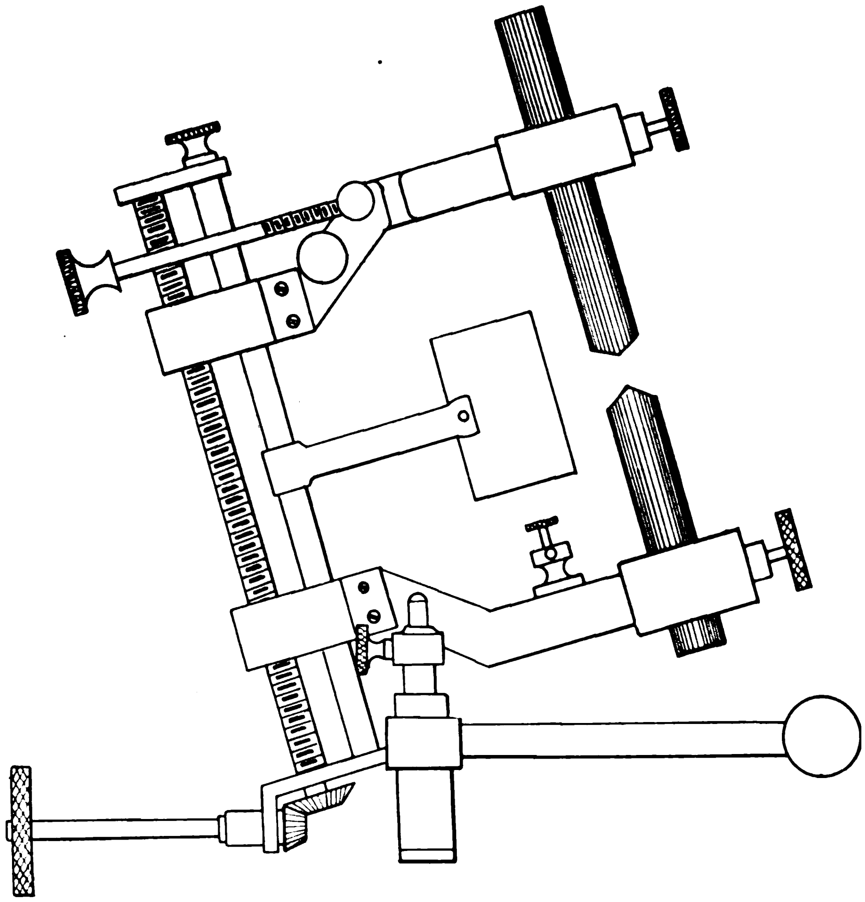

Fig. 5.

While the carbon holders are adjustable by screws, the frames are held in place on the posts by means of set screws. The latter adjustment must be made permanent, then the lower carbon can be set right, taking an opportunity when it is possible to try the light and set it so that neither shadow nor blue cloud will appear on the screen.

Having secured this on one, the other can be set just like it, taking care to measure the length of carbon used on the upper part.

When setting up a stereopticon for use on a direct current, it is necessary to know that it is wired so that current passes down the upper to the lower carbon for the following reason. The carbon which receives current first burns much faster than the other, as particles seem to be taken from it and deposited on the other. The screws are given pitches that make them travel accordingly, thus always keeping the arc central, but the upper thread is much coarser than the other, or else the arc would remain central but a short time.

To test the wiring proceed as follows: Make necessary connections and turn on current; let it remain on for about 5 minutes, then turn it off and watch the ends of carbons. If the upper one remains red longer than the other, it receives current first and is therefore positive, which is correct. If the lower retains the red color longer, the wires are connected wrong and must be reversed.

Because the wires are connected correctly at first, is no guarantee that they will always be so, because a stereopticon usually takes current from an incandescent lamp system, and for this service the current may travel in either direction and work equally well, therefore if the electric station employes change the wires while making repairs or renewals, they consider that no harm is done.

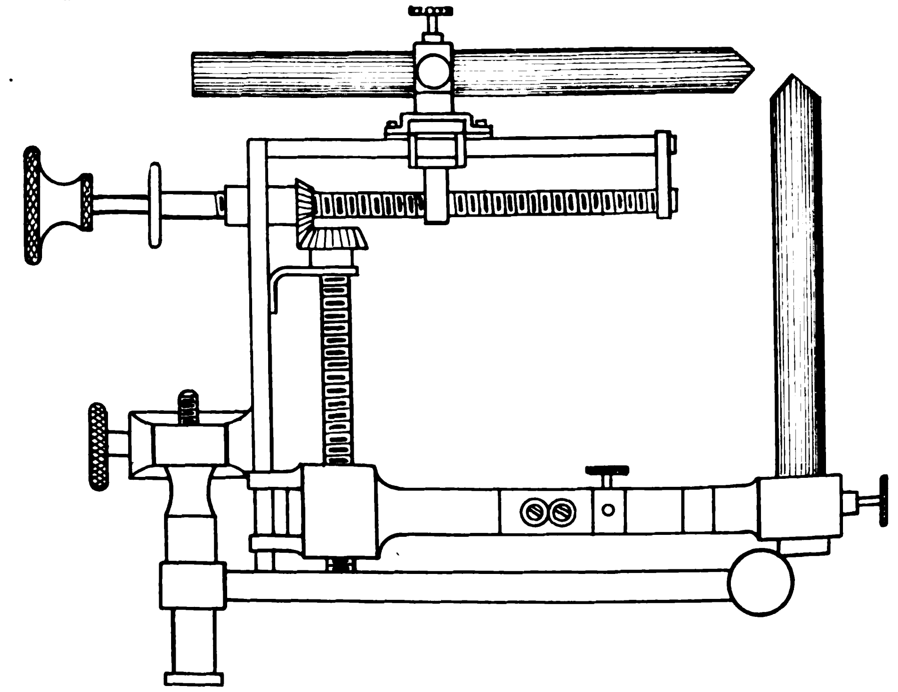

Fig. 6.

An incident of this kind nearly spoiled the operation of my stereopticon one evening, but it was discovered in time to prevent trouble. While making repairs, linemen had reversed the street connection, thus causing current to travel in the opposite direction.

Where an alternating current is used, wires may be connected in the most convenient way, as it makes no difference with the carbons, for both burn away equally. This calls for different regulation, which is secured by giving the upper and lower threads equal pitch, thus moving the carbons alike.

These arcs generate much heat, therefore when first turned on they should be at least 8 inches distant from the condensing lenses. After burning a few minutes in this position they may be slowly moved forward until in their proper places. This results in gradually heating the lenses, thus avoiding unequal expansion which may break them. I have seen a fine set ruined by heating them too quickly, although the culprit was a professional operator.

Automatic carbon feeders are considered superior by some operators, but the simple hand feeder is not without advantage, for it is always under control, while the more expensive kinds are much more liable to fail when wanted badly, to my certain knowledge.

The hand feeder needs slight adjustments at frequent intervals, but this can be done without interfering with other duties.

There are two good ways of locating carbons in a stereopticon, one of which is shown in Fig. 5. Here both are in line, but are set at an angle to the perpendicular. The object is to present the lower end of the upper carbon to the lense, as here is where the light is brightest. It answers this purpose well, giving a powerful light that will show across the largest halls and lecture rooms we have.

Fig. 6 shows another plan for locating carbons in which the positive is horizontal and must be wired accordingly to receive the current. The negative is vertical and is connected to the return line of the circuit. This refers to a two-wire system. If put on a three-wire system it is wired as shown in Fig. 1.

SERIES ALTERNATING ARC LIGHTING.*

BY E. P. WARNER.

(Continued from page 126.)

PRACTICAL ARC LIGHTING.

In the past we have heard much regarding the relative lighting efficiency of different classes of arc-lamps; the change from an open arc system to the alternating inclosed arc system often brings up the question of comparative intensity of light. Lighting committees and station managers must be satisfied regarding that point before they can make an intelligent selection of a system. The old commercial standard open arc lamp of 450 watts or 2,000 nominal candle power as adopted by the National Electric Light Association has been an accepted standard for many years. Lamps of lower wattage have been used extensively, but the 450 watt lamp has come to be pretty generally recognized as best adapted for street lighting.

A 450-watt alternating inclosed arc lamp is fully equal to the old open arc direct current for street illumination in respect to the amount of light given, and far superior to it in the matter of lighting effect as demonstrated by the increased field of vision. The bright ring of light on the street, and the dark spot under the open arc lamp are familiar to us all, but with the inclosed arc both are absent and a good average illumination of this field is obtained which, for the purpose of vision, is much to be preferred. At a distance of 150 feet the light from the alternating arc fully equals that of the open arc and beyond that distance the difference is distinctly in favor of the former. I am here proceeding on the assumption that lamps are hung at the same height. We find, however, that the alternating lamp may be hung three or four feet lower than the open arc, with a still further improvement in the effective illumination.

In the substitution of series illuminating arc lamps for the open arc in tower lighting the results have been exceedingly gratifying. Lamps were used of about 420 watts at the arc with 18-inch metal shades, white enameled on lower surface. It was found that the light at and near the base of the tower was very much greater, while the general average lighting at a distance from the tower was fully equal to that given by the open arc. No adverse criticism of the conditions after the change was offered by the people living in the neighborhood, and quite a number of favorable comments were volunteered touching the increased steadiness and more uniform distribution of the light.

CENTRAL STATION EQUIPMENT.

In the equipment of a station for the operation of series alternating arc lamps, the choice of suitable switching and controlling devices becomes an important matter; not that these details are extraordinary in number or complication, but for the reason, as often happens, that there are several good ways of doing the same thing.

A switchboard should have a system of stab switches, one for each of the two terminals of a circuit, so arranged that it may be transferred from one system of supply to another, and so that any circuit can be readily disconnected from its source of supply. The first provision is made with a view to permanency of operation of a circuit. Failure of a transformer or regulator should not compel the shut-down of a circuit for more than a very short length of time, and a simple means should be provided for bringing into service a new source of supply. This is ordinarily an extra regulator and transformer properly installed and connected to the switchboard, held ready for use in emergency. In very large installations it is necessary to have a number of such extra transformers and regulators, with connection busses running the entire length of the board, thus permitting the connection to any arc circuit by means of stab switches. Transfer busses for interchanging the circuits are not used in the present practice to any great extent, it being found unnecessary to make transfers very frequently or to any very great extent. A good reliable ammeter should be installed in each of the arc circuits. This need not be an expensive instrument, but should be one reasonably accurate and allowed to always remain in circuit while same is in use. Where very high potentials are used, it is customary to use a current transformer to actuate the ammeter in order to insulate it from the circuit and thus render it more safe to handle, and reduce the liability of crossing to other instruments on the board. Where aerial lines are used, a good system of lightning arrester should be installed at a point on the circuits immediately after entering the station. It has been found desirable to disassociate the lightning arrester installation entirely from the switchboard proper, making it a special feature of the installation.

Transformers and regulators can be installed in a separate room or building, if desired, and generally speaking this is a good plan, for the reason that it more or less isolates different portions, thus reducing the risk of injury or loss from fire. The transformers used in many of the systems, where inductive regulators are employed, are of the ordinary constant potential type and may be either oil insulated or air cooled. Generally speaking, the efficiency of these transformers can be as high as that of ordinary constant potential transformers used with non-inductive load, and the combined efficiency of a transformer and inductive regulator supplying an arc circuit is fully equal to that of the best form of tub transformer under any stage of load.

The usual practice to-day in the matter of regulators is to have all regulators of full load capacity so that they not only serve as current regulators for small changes of load and voltage, but act also as safeguards in case of a complete short circuit of an arc circuit. Arguments have been advanced against this practice, claiming that it was unnecessary to provide such an extreme range of regulation and that safety from short circuits could be provided by more inexpensive means. Whether this is true or not has not been demonstrated by any very extended practice.

Of all automatically operating regulating devices known in the engineering world to-day, the inductive regulator stands forth as one of the most perfect pieces of electrical mechanism known in the art. It has been found so perfectly reliable in its operation that the average station manager will question the accuracy of his ammeter before he will that of the regulator.

It is not an uncommon thing to hear the remark made when the current reads wrong, that "the ammeter must be off." A regulation of current to within 1-10th of an ampere, under quite extreme fluctuations of load and voltage, is easily accomplished, and this so quickly that there is scarcely a noticeable fluctuation of the lighting power of an arc lamp in series, even when 10 or 15 per cent. of the lights are extinguished at once. It is not a good plan to have regulators retarded by the action of the dash pots or other retarding devices. Perfect reliability of action is best secured by leaving the coil free to move and relying on the magnetic conditions to bring about stability in action and position.

---

* Paper read at the 13th annual convention of the Northwestern Electrical Association, held at Milwaukee, Wis., Jan. 18-20, 1905.

In the mechanical construction of regulators it should be observed that they are strong, accessible, free from excessive friction in all moving parts, readily adjustable to load conditions and capable of operation at high efficiency and power factor, and operate with little if any noise. Electrically they should be well insulated, sufficient ventilation should be provided in all portions of the windings to prevent accumulation of heat and excessive high temperature in any part.

(*To be continued.*)

ELECTRIC RAILWAY OPERATION IN A GREAT CITY.

During the course of a carefully prepared speech, delivered at the 248th meeting of the New York Electrical Society on February 15, Herbert H. Vreeland, president of the Metropolitan Street Railway Company, exhaustively reviewed the question of urban transportation. He neglected no side of the matter, taking up its physical and financial phases, which he discussed with the authority to which his long and wide experience in this particular field entitles him.

Mr. Vreeland apologized for the sermonizing tone his address took on in parts, but he declared it was impossible to dissociate his words from this element, particularly when he undertook to point out the method in which progress and evolution had been utilized in the solution of the confronting problem. He found the personal element to play no insignificant part in the recognition of such advances, and, with the poet, extolled "the uses of adversity."

"You are dealing with the most interesting problem that now engages the practical ingenuity of men," said Mr. Vreeland in his opening. "The azure of speculation seems nowhere so illimitable as in the region which your science seeks to explore.

"The world is as little interested in the man of affairs and action who gets too far ahead of the procession as in the laggard who falls behind. Living in the future is fine, but living in the present is more comfortable. If you are going to be useful, or at all events, successful, you must train your minds in the accomplishment of something out of which your contemporaries can take credit and satisfaction, and there is nothing in which their interest is keener than in the thing that facilitates the present doing of each man's present business. This is the problem of transportation."

Apart from the many and varied uses in which new inventions make possible the employment of electricity, Mr. Vreeland indicated the greatest value to be obtained from those discoveries which permit application for the betterment of existent conditions. There is a system in everything, he declared, and he endeavored to explain and eulogize the system of street railroad operation so that the trained minds of his hearers might be able to discern which parts were permanent and susceptible to improvement and which were or soon would be ready for displacement. The matter of city transportation he believed to be one of the most important among the world's "wants." Discussing this, the speaker said:

"The temper of the people is the most important part of every great question today, whether it is a question of private business or public affairs. The public never troubles itself to be consistent. It is no odds to the public that what it wants to day is in conflict with what it wanted yesterday. In the same breath, indeed, it will insist upon certain conditions, and then demand results that can flow only from conditions precisely the opposite. This is well illustrated in the controversies that are now going on about combination and competition in great industrial enterprises. Profoundly offended at the perils—mostly fancied—to which combination exposes the public interest, its every agent, the press, the public, the bar, the legislatures and the courts, will nevertheless require those useful results that only combination will produce. You are listening to-day to a large chorus of demand that there shall be free and open competition among transportation companies, and from the same voices an equally loud demand that the passenger shall be carried between the furthest extremes for the smallest fare.

"To-day the street surface railroads are combined throughout Manhattan and the Bronx; but combination will not end there," he went on. "I speak now not as a railroad president with a business scheme in his head; I speak as a student of material conditions to other such students. The public demand for facilities, for convenient routes and cheap fares is never hushed. Concession only serves to provoke a larger demand, and at the very bottom of every question that can arise in your minds as to how you will adapt the power of electricity to the problem of transportation must be to help the railroad to discover a means of satisfying this inevitable public requirement consistently with the right of its stockholders to expect a dividend upon their investment."

He was convinced, said the speaker, that with the general development of the system, due to new inventions and perfecting the old ones, the employment of electricity "in the movement of trains over long distances is close at hand." When he viewed the fact that the evolution of the horse drawn, railless omnibus into the modern electric car was the work —wonderful as it seemed—of less than twenty years, he was at a loss to attempt to place limitations upon the accomplishments of the future.

Then Mr. Vreeland took up the economic side of the question. He said: "It is fortunate for you that in these days of combination the president of a great corporation is no longer its owner with his thoughts solely upon the immediate recovery of his investment. Combinations —call them trusts if you prefer—by the very fact that they represent so great an investment that no one man—indeed, no small group of men—is ever in secure and absolute control, afford the best assurance that any business method has ever provided in the history of trade of the largest opportunity for men of force and brains. The ownership of a property capitalized for $25,000,000 or $50,000,000, bonded for $50,000,000 or $100,000,000, is distributed all over the country and lodged in the hands of thousands and often tens of thousands of investors.

"However identified it may be in the mind with the genius of a single individual who may have created or brought it together, the fact invariably is that his personal financial interest in the concern bears only a trifling proportion to the total investment, and well he knows that his control is no control at all, but merely that measure of authority which he can justify by an annual dividend. He knows, moreover, that its continuance depends not so much upon what he can accomplish to-day as upon the steady, constant and permanent value that he can give to his corporation's securities. He and his associates—for of himself he amounts to little—perfectly realize that they must keep their eyes constantly trained on the future, and their minds are always receptive, therefore, to a man with an idea."

One attack upon combinations Mr. Vreeland answered in these words: "You are all familiar with the claim that the consolidation of great properties is against the interests of the individual, of labor as a class, of inventors as a class, of youth and ambition however employed, unless it is backed with money. It is constantly alleged with most elaborate sophistries that the ultimate result of consolidations is a reduction of working forces and that the effect of elaborate organization is to thwart ability and stifle hope. I suppose that, in a modified way, the experience of my corporation is that of every other. If it is, this is the fact: Computing on a mileage basis, since the street railroads of New York City were consolidated into the Metropolitan system, and since the electrical engineer drove the electrical force against the wheels of our cars, we employ three times the number of men that were formerly employed upon the same mileage. We have one president, it is true, instead of twenty odd, and we have reduced the number of secretaries, managers, treasurers and superintendents and the like, but as to the working force, from which the loudest protest is heard against combination, it is three times as great and its wages per individual have increased 15 per cent.

"Favoritism is a bygone method," said Mr. Vreeland. "In our organization," he continued, "we are absolutely dependent upon ability. What should an electrical engineer, who is a director's son, but a man of no particular capacity, weigh with me against an electrical engineer through whose device I can start my cars more easily, stop them more swiftly, govern them more accurately, when my relation to my company depends solely upon the value of securities owned by ten thousand individuals scattered throughout the land? Influence may secure to youth an opportunity, it may set his foot in the right direction, but there never was a time when the length of his stride depended so entirely upon the man himself as they do to-day."

Mr. Vreeland deprecated the too rapid advancement of electrical science from the standpoint of economy. "It is no unusual experience for us to buy and install a very expensive electrical device," he said, "to discover that it does not work in perfect synchronism with other parts of the machine or with other machinery necessary to be operated with it, and to have it said to us:—'Nothing ails the new motor; it is a good motor. What you want is a new governor. Since we made that motor we have made some other new thing to go along with it; you must get that.'"

Proposals Invited.

The Navy Department, through the Bureau of Supplies and Accounts, is inviting sealed proposals until March 21 for furnishing the New York, Boston, League Island and other Eastern navy yards with the following: Schedule 99, electric cable; schedule 100, electrical supplies. Blank proposals will be furnished on application to the Navy Pay Office in New York or to the Bureau at Washington. Applications should designate the schedules desired by number.

The Bureau of Yards and Docks, Navy Department, will open bids on April 15 for furnishing a five-ton electric traveling crane at the Puget Sound Navy Yard. Specifications can be seen at the Bureau or will be furnished on application to the commandant of the yard named. On April 1 the Bureau will open bids for furnishing three electric traveling cranes at the Portsmouth, N. H., Navy Yard.

F. A. La Roche Dead.

F. A. La Roche died in the Presbyterian Hospital, New York, Saturday morning of a complication of diseases. He had been ill for about six weeks. He was forty-three years old, and was interested in various electrical and motor companies.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED FEB. 28, 1905.

Electric Railways and Appliances.

783,458. Trolley. James A. Norton, Wilkes-Barre, Pa., assignor of one-half to William L. Raeder, same place. Filed Dec. 23, 1904.

783,687. Electric Railway. Alfredo Diatto, Turin, Italy. Filed Nov. 20, 1902.

783,751. Insulated Railway-Rail Joint. Edward D. Lewis, Syosset, N. Y., assignor to the Continuous Rail Joint Company of America. Filed June 1, 1904.

Electric Lights and Appliances.

783,509. Electric-Lighting System. Albert G. Davis, Schenectady, N. Y., assignor to the General Electric Company. Filed March 4, 1899.

783,645. Electric Lamp and Socket. Charles G. Perkins, Hartford, Conn., assignor to the Perkins Corporation, same place. Filed July 30, 1904.

783,737. Electric Candelabrum. Charles E. Weeks Providence, R. I., assignor to the Gorham Manufacturing Company. Filed June 30, 1903.

783,741-743. Electric-Lamp Adjuster. Henry D'Olier Jr., Philadelphia, Pa. Filed March 5 and April 2, 1904.

783,876. System of Electric Lighting. John Lindall, Boston, Mass. Filed Oct. 17, 1904.

783,974. Electric-Arc Lamp. Charles A. Nagel, Allegheny, Pa., assignor of two-sixths to William G. Anderson, and one-sixth to Max E. Nagel, same place. Filed April 14, 1904.

Electrical Machinery and Apparatus.

783,409. Frame for Dynamo-Electric Machines. Bernard A. Behrend, Norwood, O., assignor, by mesne assignments, to the Bullock Electric Company. Filed Nov. 6, 1903.

783,430. Insulating Base-Block for Electric Equipment. Monroe Guett, Hartford, Conn., assignor to the Hart & Hegeman Manufacturing Company. Filed June 13, 1904.

783,462. Time-Limit Starting and Controlling Rheostat. Robert H. Read and William O. Yates, Schenectady, N.Y., assignors to the General Electric Company Filed July 21, 1904.

783,495. Oscillator for Electric Machines. Edwin C. Wright, Newport, Ky., assignor, by mesne assignments, to the Bullock Electric Company. Filed May 26, 1902.

783,503. Temperature-Compensating Device for Thermo-Electric Measuring Instruments. William H. Bristol, New York City. Filed Dec. 15, 1904.

783,508. Emergency-Brake. Fred B. Corey, Schenectady, N. Y., assignor to the General Electric Company. Filed June 16, 1904.

783,513-514. Regulator. Richard Fleming, Lynn, Mass., assignor to the General Electric Company. Filed Sept. 26, 1903, and April 25, 1904.

783,532-533. Transformer and Transformer Protection. Walter S. Moody, Schenectady, N. Y., assignor to the General Electric Company. Filed July 21 and July 25, 1904.

783,537. Motor-Controller. William A. McTaggart, Schenectady, N. Y., assignor to the General Electric Company. Filed Aug. 15, 1904.

783,543. Electric Chain-Welding Machine. Adolph F. Rietzel, Lynn, Mass., assignor to the Thomson Electric Welding Company. Filed Oct. 15, 1903.

783,557. Power-Transmitter. Calvin P. H. Vary and Hermon D. Hutcheson, Newark, N. Y. Filed Dec. 9, 1903.

783,612. Electric Switch. Percy L. Clark, Bristol, Conn., assignor to A. L. Clark, Elgin, Ill. Filed June 23, 1904.

783,651. Transformer for Electric Metal-Working Apparatus. Elihu Thomson, Swampscott, Mass., assignor to the Thomson Electric Welding Company. Filed Dec. 4, 1903.

783,911. Electric Push-Switch. George B. Thomas, Bridgeport, Conn., assignor to the Perkins Electric Switch Manufacturing Company, same place. Filed June 13, 1904.

783,965. Commutator. Hermann A. Knoener, East Orange, N. J., assignor to the Crocker-Wheeler Company, Ampere, N. J. Filed July 25, 1904.

783,977-978-980-981. Electric Switch. William H. Powell, East Orange, N. J., assignor to the Crocker-Wheeler Company. Filed Nov. 28 and 30, 1903, and Oct. 24, 1904.

783,979. Rheostat. William H. Powell, East Orange, N.J., assignor to the Crocker-Wheeler Company. Filed Oct. 24, 1904.

783,989. Apparatus for the Commutation of Direct-Current Dynamo-Electric Machines. Frederick W. Young, Ampere, N. J., assignor to the Crocker-Wheeler Company. Original application filed April 17, 1902. Divided and this application filed June 26, 1902. Renewed Sept. 12, 1904.

Telephones and Telephone Apparatus.

783,419. Telephony. Edward A. Buell, Dekalb, Ill., assignor to the Selective Signal & Telephone Manufacturing Company, Sycamore, Ill. Filed May 2, 1904.

783,510. Telephone-Exchange System. William M. Davis, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Manufacturing Company. Filed May 20, 1903.

783,750. Phonic Apparatus. Daniel Higham, Bridgeport, Conn., assignor to the Highamophone Company, Jersey City, N. J. Filed Dec, 12, 1904.

783,861. Telephone-Switch. Albert W. Hammer, Willow, Ind. Filed Jan 25, 1904.

Miscellaneous.

783,480-481. Starting Means for Gas or Vapor Electric Apparatus. Percy M. Thomas, Pittsburg, Pa., assignor to the Cooper Hewitt Electric Company. Original application filed Feb. 3, 1903. Divided and last application filed May 6, 1903.

783,482-784,016. System of Electrical Distribution. Percy H. Thomas, Pittsburg, Pa., assignor to the Cooper Hewitt Electric Company. Original application filed Feb. 7, 1903. Divided and last application filed May 6, 1903.

783,546. Insulation for Edgewise-Wound Coils. George H. Rupley, Schenectady, N. Y., assignor to the General Electric Company. Filed July 21, 1904.

783,708. Generating Low-Frequency Currents. William Stanley, Great Barrington, Mass. Filed Nov. 11, 1903.

783,809. Electric Elevator. Ernest H. Vogel, New York City. Filed April 11, 1904.

783,996. Burglar or Fire Alarm System. John W. Culp, Elkhart, Ind., assignor to the Modern Burglar & Fire Alarm Company, same place. Filed June 28, 1904.

784,013. Method of Generating Low-Frequency Currents. William Stanley, Great Barrington, Mass. Original application filed Nov. 11, 1903. Divided and this application filed July 7, 1904.

THE TELEPHONE WORLD.

Independent Companies Hold Annual Meeting.

Over 50 stockholders, officers and managers of the 28 Independent telephone companies in the Sixth District of Ohio, comprising Montgomery, Miami, Darke, Shelby, Clark, Greene, Champaign, Logan and Madison Counties, met at the Dayton Home Telephone Company Building a short time ago and talked business. In that district there are 30 exchanges, 1,482 stockholders and 25,000 subscribers.

I. H. Theddick, of Sidney, was elected vice-president, and H. P. Miller, of Dayton, was chosen to represent the district at the meeting of the National Independent Telephone Association in Chicago, June 20 and 21.

Charles E. Guile and A. M. Taylor, of Penn Yan, N. Y., representatives of the Inter-Ocean Telephone & Telegraph Company, have been in the vicinity of Poplar Ridge and Scipioville, in an effort to organize an Independent telephone system for the benefit of the farming community and others who desire such a service. It is understood that a company is about to be organized, to be known as the Inter-Laken Telephone Company, which will furnish the capital and commence construction as soon as the weather conditions will permit. The best of material and telephones will be used, and everything will be put up in first-class order. The company will be connected with the Inter-Ocean Telephone Company at Auburn, thus giving the long-distance service. It is expected to reach King's Ferry, Aurora, Scipio Center, Fleming and all intermediate points.

The Dakota Central Telephone Company has completed arrangements for the construction of an extension from Gettysburg to Pierre, S. D., and work will begin as soon as the ground thaws. The proposed extension is a completion of the line from Bowdle to Pierre, which was started some time ago, operations being suspended when the capital fight commenced. Another line will be built in a short time from Ipswich south to Faulkton and Miller, over 100 miles of main line wires being planned in the next few months in the extensions mentioned.

John Woodward has organized a company to be known as the Cumberland River Telephone Company, and will begin at once to construct lines from Barbourville, Ky., to Keely, Tenn., via Williamsburg. Material for the line has been bought, and the company will be incorporated at once with a capital of $5,000. John Woodward will be president and general manager, and L. R. Benjamin, of Barbourville, secretary and treasurer.

The Clearwater, Minn., Telephone Company has arranged to connect with the Northwestern Telephone Company, and is wiring the town and putting in a large switchboard.

The Western Wisconsin Telephone Company of Arcadia has filed an amendment to its charter increasing its capital from $50,000 to $60,000; John G. Gaveny, president, and Emil Maurer, secretary.

The Nebraska Telephone Company has begun the installation of an exchange at Raymond.

Independent Telephone Men Hold Interesting Meeting.

Independent telephone interests were thoroughly considered at a meeting held about a week ago at the Hartman Hotel, Columbus, O., of representatives of the 160 exchanges in two districts comprising 24 counties, including Franklin and others in the southern part of the State.

The conference was presided over by Dwight E. Sapp, of Mt. Vernon, and among the 100 telephone men present were: J. B. Hoge, of Cleveland, president of the National Organization; Frank L. Beam, president of the Ohio Independent Telephone Association, and M. B. Overly, general manager of the United States Telephone Company.

There was a general discussion of telephone conditions, from the viewpoint of the Independents. Among the subjects considered were the recognition of the rights of the different companies; rules governing the operation of the exchanges; uniform system of bookkeeping, publication of telephone directories and the best method of advertising.

President Frank L. Beam of the State Association read an interesting report of the business of the Independents, compared with that of the Central Union, in the two districts. He presented this table:

	Ind.	C. U.
Number exchanges............	160	28
Number toll stations............	360	132
Number subscribers............	43,923	15,078
Number stockholders............	1,575	0
Number companies............	63	1
Age companies, oldest.........	8	20

The counties included in the districts represented are:

Ninth district—Crawford, Richland, Ashland, Wayne, Holmes, Morrow, Knox, Union, Delaware, Licking, Franklin, Fairfield and Hocking.

Fourth district—Pickaway, Fayette, Vinton, Jackson, Scioto, Lawrence, Pike, Adams, Highland, Clinton and Ross.

Delegates on a basis of one for each 1,000 'phones were elected to the State Association, which meets in Columbus on March 30. Officers were also elected for the two districts.

The meeting was probably the best attended in the history of the two organizations, and according to one of the officers, is an indication that the Independents are enjoying prosperity.

The Lorimer Automatic Telephone Company was lately organized at Augusta, Me., for the purpose of dealing in apparatus and property pertaining to the complete operation of telephone lines or systems. Its capital stock is $10,000,000. The officers are: President, G. R. Hadlock; treasurer, E. F. Whittum, both of Augusta.

The Belmont Telephone Company, of Bellaire, O., has purchased the Pultney Company's telephone lines which are operated at Shadyside.

The Guysville, O., Telephone Company has increased its capital from $3,000 to $6,000.

The Central Telephone Exchange Company has been granted a franchise in Rogers, Ark.

Telephone Improvements.

H. J. Pettingill, president of the Northwestern Telephone Exchange Company in Minneapolis, is about to take up the building of several hundred miles of pole lines in new territory. It is planned also to string 2,000 miles of copper on toll lines in the three States in which the company operates. Important long-distance extensions are considered also.

The operation of the toll service in the twin cities is to be consolidated in the new East Side Building. The Northwestern Company will connect there with the operating service of the American Telegraph & Telephone Company of Chicago.

The opponents of the Bell Company are determined to establish an Independent telephone service in Middletown, N. Y., and it has been decided to organize a new Independent company there to be ready to make contracts and secure any desirable property.

A meeting will be held by the stockholders of the Dundee. N. Y., Telephone & Telegraph Company, Friday, March 10. The stockholders are desirous of increasing the capital stock of the company to the amount of $10,000, and the meeting is called for that purpose.

A new telephone company, capitalized at $4,000, has been formed in Candor, N. Y.; another concern known as the Rose Telephone Company of Bloomville, N. Y., with a capital stock of $15,000, has also been organized.

The telegraph and telephone apparatus in Japan is of the most modern type. Tokio and Yokohama installed their first telephone systems in 1890.

R. H. Porter and E. W. Porter have organized the Potlatch Telephone Company and will engage in the telephone business in Juliaetta, Kendrick, Southwick and Leland, Idaho, as well as through the country adjacent to these places.

The Pope County Telephone Company, of Golconda, Ill., has increased its capital stock from $5,000 to $15,000.

More than $200,000 will be spent by the Colorado Telephone Company in extending its line in New Mexico.

The Lebanon Telephone Company is to operate lines throughout New Jersey.

The Atlantic City, N. J., city council has decided that telephone and telegraph wires must be placed underground.

Telephone Incorporations.

The Maple Lake Telephone Company, Maple Lake, Minn. Capital stock, $10,000. Incorporators: A. W. Mary, F. S. Bissell, P. H. Lealey, W. E. Freeney and J. E. Madigan.

The Hector Telephone Company, Hector, Minn. Capital stock, $25,000. Incorporators: Emil Larson, Edwin Dahlgren, Justin Johnson and E. M. Ericson, Palmyra; Harry L. D'Arms, Henry L. Torbenson and George S. Eichmiller, Hector.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Aguilar, Col.—A company with a capital of $10,000 is being formed to construct a municipal electric light plant here. A. R. Lindsey, Morris Pitts, H. Pinamonti and Dr. A. B. Harbison are interested.

Alma, Neb.—At a recent special election this town voted in favor of issuing bonds for electric lights and a waterworks system. As soon as the bonds are disposed of the contract will be let for the two plants and work will be commenced this spring.

Berkley Springs, W. Va.—T. H. B. Dawson, Silas J. Honernall, Romanus Hunter, of this place, and others, have incorporated the Berkeley Springs Light & Water Company with a capital of $25,000, to operate a waterworks and electric light system.

Burlington, N. C.—This city will enlarge the electric light plant and install additional engines and dynamos. W. A. Hall, mayor.

Carlisle, Ky.—The citizens' electric light plant was recently destroyed by fire. The loss is about $10,000 with $2,500 insurance.

Creston, Ia.—The organization of an electric light company is proposed. Mayor C. J. Sullivan is at the head of the project.

Dallas, N. C.—The city will petition the Legislature to grant an election for voting on the issuance of $5,000 of bonds to install a system of electric lights. Address the mayor.

Decatur, Ill.—The Consumers' Gas & Electric Company, with a capital of $50,000, has been incorporated by W. M. Bering, Charles S. Needham and others, to manufacture light, heat and power.

Dickson, Tenn.—William McDonough, proprietor of the Dickson Machinery Repair Company, is making arrangements to put in an up-to-date electric light plant whereby he will be enabled to furnish light to business houses and residences.

Far Rockaway, N. Y.—The residents of the Wave Crest section have grown tired of waiting for the city to have lights placed throughout that territory, and now propose to have it lighted by electricity, at their own expense, and a subscription will be raised for this purpose.

Fayetteville, N. C.—The city contemplates enlarging its electric light plant at a cost of $30,000.

Hickman, Ky.—The electric light plant in this city was lately destroyed by fire.

Higbee, Mo.—It is reported that the Higbee Electric Light, Heat & Power Company has engaged W. K. Palmer, C. E., 718 Dwight Building, Kansas City, to prepare plans and supervise the construction of the proposed electric light plant.

Hopkins Station, Mich.—W. F. Nicoll of this place, assisted by experts from Grand Rapids, has made plans to establish an electric light plant here.

Lawrenceburg, Ky.—The Lawrenceburg Electric Light Company has completed its organization with J. M. Johnson, president; E. R. Ripy, vice-president, and Dr. C. A. Leathers, secretary, and will at once arrange for the installation of an electric light plant.

Marion, S. D.—J. A. Heeren and others have been granted a franchise for the installation of an electric lighting system.

Mayfield, Cal.—A company has been organized of local capitalists for the purpose of establishing an electric lighting plant, to furnish light and power for this town and vicinity.

Ness City, Kan.—Milo Heatwole of this city, proprietor of the Roller Mills at Walnut, contemplates installing an electric light plant.

Oxnard, Cal.—This city is to have a new electric light and power plant to cost $100,000.

Plattsmouth, Neb.—The Nebraska Lighting Company has decided to expend $25,000 for improvements in its gas and electric light plant.

Shelbyville, Ill.—The Taylorville Gas Company and the Taylorville Electric Light Company have been consolidated, under the name of the Taylorville Gas & Electric Company. Its capital stock is $127,000. J. N. C. Shumway will be the local manager.

Springfield, Ill.—The Springfield Electric Light & Power Company will expend $20,000 in improvements. New machinery will be installed.

Stillwater, Minn.—The Stillwater Gas & Electric Light Company contemplates installing a new system of street lighting in this city.

Sturgeon, Mo.—The citizens have voted to issue bonds for the purpose of installing an electric light plant.

Urbana, O.—C. H. Marvin has secured a franchise for electric light and hot water heating, and announces that steps will be taken at once for the erection of a modern plant.

Winona, Minn.—Winona County farmers on the roads leading out from Minnesota City to Winona, Fountain City, Rollingstone and to Lewiston, are to be provided with electric light and power, light for illuminating their farm houses, and electric power for driving cream separators, feed mills, etc.

STREET RAILWAYS.

Anderson, Ind.—A trolley will be run from this city to Newcastle through Middletown. It will be built during the summer.

Barberton, O.—The Barberton, Wadsworth & Western Traction Company has been organized with the following officers: President. B. M. Clemdenning; secretary, O. S. Everhard, and others.

Bellefontaine, O.—A movement is on foot for the establishment of a new electric line which will be financed by New York capital.

Decatur, Ala.—L. Watt Allen, of this city, is engaged in securing rights of way for an electric line from Nashville, Tenn., to Huntsville, Ala., and is meeting with success.

Elmira, N. Y.—The Chemung Valley Traction Company will operate an electric railroad 18¼ miles long from this place to Waverly, Tioga County. Its capital stock is $700,000. Directors: E. E. Buchanan, Boyd McDowell and George McCann.

Garfield, Wash.—The Spokane & Inland Electric Railway Company expects to build a line to this city.

Lancaster, Pa.—The Lancaster & Safe Harbor Electric Railway Company has been chartered with a capital of $54,000.

Marion, O.—The Marion Electric Railway, Light & Power Company is planning to install additional engines and boilers in its plant. George Whysell is general manager of the company.

Oklahoma, Okla.—J. S. Robinson, an influential farmer of Council, is authority for the statement that parties recently visited this part of the country interviewing citizens relative to right of way and donations for an interurban electric railway to connect this city and El Reno.

South Haven, Mich.—Mr. Applegate has been granted a franchise to build an electric railroad in this village.

Steubenville, O.—A company has been formed to build an electric railway from this city to Wellsburg, W. Va.

Utica, N. Y.—It is announced that the first steps to equip part of the West Shore Railroad with electricity will be taken in one week. The section on which the first work will be done lies between Frankfort and Herkimer, a distance of about four miles.

Valley City, N. D.—E. T. Bradley will apply for a franchise to operate a trolley line within the city limits.

POWER PLANTS.

Cincinnati, O.—J. V. B. Scarborough has purchased a site and will erect a new power plant.

Fresno, Cal.—The construction of another power plant near the Crane Valley reservoir, having a capacity of 3,500 hp., will shortly be commenced by the San Joaquin Power Company. William G. Kerchoff, of Los Angeles, is president.

Jackson, Mich.—W. A. Foote will erect a new $100,000 power plant.

BIDS WANTED.

Bullock, N. C.—The Royster Manufacturing Company is in the market for a 60 or 75 hp. boiler.

Fulton, Ky.—J. N. Hall, president of the Baptist Publishing Company, of this city, will be in the market for a motor for operating printing machinery.

Gaffney, S. C.—Carroll & Co. want one good second-hand 10 or 12 hp. traction engine.

Memphis, Tenn.—The Pelican Biscuit Company wants prices on electrical equipment.

Newport, Tenn.—The Sanitarium Tablet Company wants prices on electrical equipment.

Pine Bluff, Ark.—The Bluff City Brick Company, of which J. W. O'Neal is manager, 2003 West Fifth avenue, wants prices on engines and boilers.

Richmond, Va.—The Union Trunk & Bag Company wants prices on an engine and boiler.

Savannah, Ga.—The Savannah Lighting Company, Montgomery street, wants prices on outside line material, meters, arc and incandescent lamps, motors, etc.

Sebree, Ky.—J. B. Ramsey, who has secured a franchise to construct and operate an electric light plant here, will be in the market for a boiler.

Shaw, Miss.—J. G. Williams wants prices on a 100 hp. stationary boiler and fixtures.

Sulphur Springs, Tex.—C. R. DeBond is in the market for an engine and boiler.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 15⅛@15¼c.; Lake 15¼@15⅜c.; casting, 14⅞@15c.

Attorney Mayer of the Illinois Tunnel Company intimates that the company may expend $100,000,000 on Chicago's undergrond system.

The annual meeting of stockholders of the Western Telephone & Telegraph Company will be held March 21 at 243 Washington street, Jersey City.

The Appellate division of the Supreme Court has dissolved the injunction restraining New York City officials from paying alleged excessive bills to the lighting companies.

The Chicago Telephone Company has declared the regular quarterly dividend of 2½ per cent., payable March 31. Books close March 27 and reopen April 1.

It is stated that there is no truth whatever in the report circulated that there will be an assessment of $5 a share on the stock of the Philadelphia Rapid Transit in June.

The men who have devoted their time and energies to the agitation for lower telephone rates in New York City confidently believe that the legislative committee will make a thorough investigation of the entire telephone question.

President Roosevelt's inaugural address was one of the shortest ever delivered. It contained absolutely nothing disquieting to the financial world. The whole address was idealistic in tone, nothing of a commercial or financial nature being discussed.

Trustees of the Massachusetts Electric Companies now express the opinion that the system as a whole is to-day in better physical condition than it has ever been; that it is well equipped with rolling stock and in position to get the full benefits of increased business.

Sutro Brothers & Co., New York, offer for sale a balance of $1,000,000 New York & Westchester Lighting Company general mortgage 100-year coupon gold bonds at 93 and interest, netting about 4.30 per cent. These bonds are secured by a direct mortgage on the property and franchises of the company.

Notice has been given to the holders of income bonds of the United Railways & Electric Company of Baltimore that a committee has been formed for action looking to the protection of bondholders. Counsel for the committee has advised its members that the terms of the mortgage securing the income bonds do not warrant the non-payment of the coupons, which are now in default.

The publication of the statement of the New York City Railway Company for the quarter ending December 31 and the six months ending on that date, started a lot of talk in the financial district on Saturday on account of some unusual changes as between the September quarter and that ending with December. What attracted the greatest attention was the comparatively small decrease in net earnings in the December quarter as compared with the decrease in the September quarter, and the very great increase in charges in the December period, making a large increase in the deficit for the quarter ending December 31. For the December quarter, the time within which the Subway was opened, the net earnings decreased $31,632 over 1903, and the decrease over 1903 for the six months was but $64,836, leaving $33,204 as the contribution of the September quarter. Apparently, therefore, the opening of the Subway did not have any very marked effect upon the Metropolitan's earnings.

EDITORIAL NOTES.

The Strike. The strike on the elevated and Subway roads in this city, which began at 4 A. M. March 7, is practically over.

The motormen and guards went out because the latter considered they were not receiving adequate compensation for their services.

The Interborough Rapid Transit Company replaced many of the strikers by men imported from Chicago and other Western cities and an attempt was made to operate trains. For the first day or two only a few trains were run at long intervals, and practically no passengers were carried. As a result the surface lines were taxed to the limit and every available carriage and automobile in the city was in demand during the early morning hours. Even then thousands of workers were obliged to walk to their places of business.

The strike, if it did nothing else, has shown New Yorkers in an uncomfortable but forceful way, how much business is dependent on the elevated railway and Subway. Men who heretofore have advocated a 3-cent fare were only too glad to get a carriage at any price to keep important engagements.

A commendable feature of the strike was that the electricians in the power houses refused to go out. These men receive good wages and have responsible positions, and in spite of much pressure being brought to bear could not be induced to leave their posts.

* * *

The Electric Extension of City Suburbs. It is very curious to note the increasing diameter of the zone, which now includes the real activities of Greater New York. The phrase is a most suggestive one, as Greater New York has become since thus designated a greater New York. The electric nerve ganglions, which a decade ago were the sources from which radiated the lines propelling electric cars but a limited distance over the city surface, have been greatly increased both in number and capacity. The Bronx is now as near to City Hall as was formerly the Harlem section, and the city suburbs have been pushed back to the extreme north in the Bronx and beyond Prospect Park in Brooklyn.

The subway will rapidly build up the section now regarded as distinctly suburban and thus the density of population to the north, south, east and west of the original seat of the metropolis will reach a new and perhaps overcrowded maximum. City building in the aggregate is now proportional to the electric railway construction. A copper web has been built over New York from which it really derives its strenuousness. The employer and employe are alike so dependent upon it that its temporary paralysis means the cessation of all industry until repaired. The city zone is an electric zone, the electric car is the maker of enormous dry-goods and amusement centers. Such growth as has been witnessed is in reality the electric extension of the city suburbs.

* * *

What the Electricians Are Earning. The scope and development of electrical industries in the United States during 1904 has been barely understood or appreciated by the busy workers in other fields.

A little illumination on the subject must prove of interest to the technical and general reader and perhaps act as an added stimulus to the beginner. Although the figures given represent gigantic amounts, comparative records show a steady if not a remarkable increase each year in the earnings and profits derived from such enterprises. First in the list as earners come the electric railways, which aggregate the sum of $290,000,000; second in earning capacity are the great manufacturing interests, representing $175,000,000; the electric light companies then appear as third with an earning capacity of $125,000,000; the telephone companies fourth with a record of $110,000,000 and the telegraph companies fifth with earnings of $40,000,000. The total runs very close to *three-quarters of a billion dollars*, and in all probability at the present rapid rate at which various important portions of steam roads are being electrified, large power transmission plants being inaugurated, and a host of smaller electrical enterprises reaching a large and healthy stage of development, a billion dollars will not fall very far short of the great new total.

At the present writing the United States possesses a degree of wealth estimated at 110 billions and many conservative and fair minded statisticians attribute a considerable portion of it to the influence of invention and the application of electricity to industrial purposes. Charles M. Harvey in the "World's Work" states that "Invention and discovery have made the 83,000,000 Americans of 1905 three times as productive as were the 23,000,000 of 1850." The striking statement, which we all realize to be true, is the increased power of each individual as a producer of wealth, through the influences of greater knowledge, by means of which more of our natural resources are turned to profit with a more far reaching economy both as regards time and effort. It seems that this vast organization of forces, internal and external, instituting the present republic, is operating, in spite of its greater responsibilities and burdens with a remarkable national and individual efficiency. It could not be regarded as egotism to claim, that this rising tide of prosperity has never been equalled in the history of any other political aggregation, either as regards its scope or the comparatively short period of its history.

An epidemic of success, is surely a record that can only be interpreted in the light of a unanimity of action and desire on the part of the great producing element of this continent.

The extensive co-operation, the new and exhilarating freedom, the vast range of the educational establishments enlisted in this cause are in the main the essential elements. Practical science, the application of organized knowledge, has won its way to the front. Its garlands of victory have been gained by initiative, perhaps the initiative best shown by a new race of American pioneers among whose names will be found none more honored than Benjamin Franklin, Joseph Henry, Prof. Morse and Alexander Graham Bell.

Could we but trace the correct relationship between cause and effect, not only to-day, but for the not far distant future, it would be found that prophesy will indicate that our national and domestic life is interwoven with electrical discovery; that the larger earnings to which this land will some day point with pride have been made by the electrician, that the loudest and busiest hum from the wheels of industry come from the titanic workshops of these new wizards of progress.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

The employes of the Interborough Rapid Transit Company of this city who refused to go on strike will be rewarded with two weeks' extra pay. Some 2,000 employes stuck by the company.

◆

President Davis of the National Electric Light Association has appointed Mr. Arthur Williams to make a report on "Municipal Ownership" to the Denver-Colorado Springs convention.

◆

According to a press report the New York Telephone Company has decided upon an average reduction of 20 per cent. in telephone charges in this city. In return the Merchants' Association must give up its efforts before the Legislature to investigate the telephone company's methods.

◆

A high speed electric line to connect Newark, N. J., and New York by means of one of the tunnels under the North River is contemplated by the Public Service Corporation of New Jersey.

◆

In Connecticut and Massachusetts combined, the New York, New Haven & Hartford Railroad Company now owns about 572 miles of single track electric lines.

◆

A special cable to the New York "Herald," March 11, says: "A practical test of telegraphy by the aid of photography was made a few days ago between Paris and London, which had not the experiment been carried out at the General Post Office would read like a fairy tale of science. The new process, known as the Pollak-Virag system, is capable of turning out the incredible number of 40,000 words an hour. The apparatus works at the rate of 72 letters per second. The details are too intricate to be given shortly, but it may be stated that sensitized paper is used. There are a small reflector and an incandescent lamp, and the writing is done with the point of a fine live wire. It looks like a pencil flame. The exposure is the three-thousandth part of a second and the development and fixing take 5 to 6 seconds each.

◆

Prof. Crew of the Northwestern University, in a paper presented before the electrical section of the Western Society of Engineers, said that "the electron theory, as it stands to-day, is merely a first step toward a more complete description, based strictly upon experimental evidence, and that the ionic hypothesis is the only one which has shown any degree of competency whatever."

◆

Secretary of the Navy Morton has made a contract with the Electric Boat Company for the construction of two submarine torpedo boats, one to cost $250,000 and the other $200,000.

◆

A dispatch from Chicago says the Chicago & Alton Railroad Company has declared war on the electric roads which are paralleling it south of Bloomington, Ill. A schedule which has just gone into effect on the Alton provides for many changes in train service in order to give better facilities for travel than the electric lines. The electric managers are preparing to meet all the steam company's "new ideas" of transportation and go them one better.

◆

The first tax sale in the city of New York since 1899 is advertised to take place on June 14. Included in the list of 122 corporations which are in arrears in taxes are the New York City Railway Company, Manhattan Railway Company and Western Union. A total of $13,200,000 is due the city, and of this amount, Metropolitan and allied corporations owe $2,569,000; Manhattan $1,950,000, and Western Union $18,000.

◆

The city of Montevideo, Uruguay, has contracted for the electrification and extension of the street railways of that place.

◆

The municipal lighting plant of Rock Falls, Ill., is to be discontinued, as it was a losing venture. The city's light will be furnished by a private company.

THE NIEDER-SCHONEWEIDE-SPINDLERSFELD SINGLE-PHASE ELECTRIC RAILWAY.

BY C. SMITH.

The Union Elektricitats Gesellschaft of Berlin has recently installed a single-phase electric railway between Nieder-Schoneweide and Spindlersfeld, Germany, which is of interest in many ways.

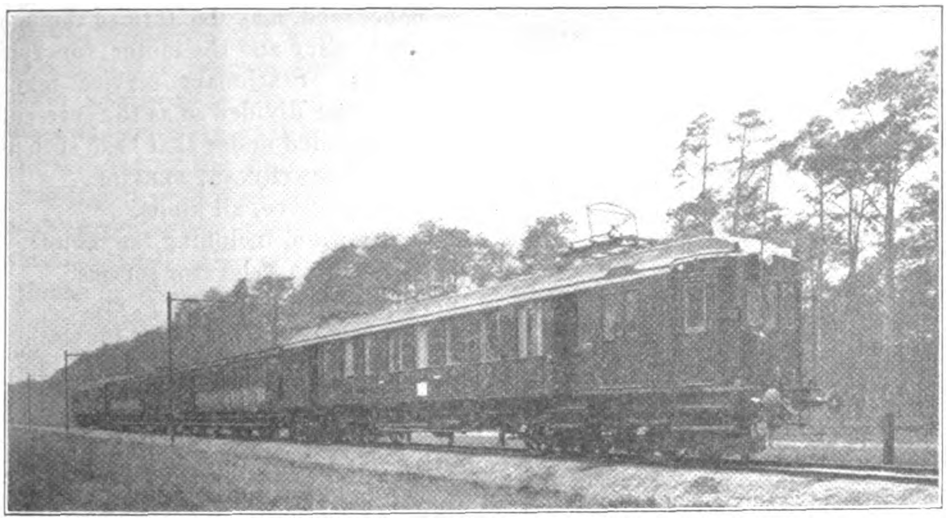

Fig. 1.—Train on the Nieder-Schoneweide-Spindlersfeld Electric Railway.

Trains run every hour during the day, one motor car being utilized for this service, but in the morning and evening a train consisting of two motor cars and three trailers in between is used as seen in Fig. 1. This train weighs about 170 tons and makes an average speed of 34.4 km. per hour.

The line is 4,082 km. long with one intermediate station, Oberspree. The current for this line is generated at Nieder-Schoneweide at a tension of 6,000 volts and a frequency of 25 cycles per second and is conveyed to overhead conductors.

These overhead conductors are supported from longitudinal suspension wires, either one or two such wires being employed for each conductor. In view of the high tension employed the method of double suspension is far safer and better than single suspension although both methods are in use, as can be seen from the accompanying illustrations. Fig. 2 shows the method of single suspension, the line being suspended from side bracket arms, while Fig. 3 shows the use of double bridle wires. It can be seen from drawing, Fig. 4, that the wire is supported freely and yet so as to provide against a failure of one of the suspension wires. Short lengths of wire connect the trolley wire to the bridle wires, which are in turn supported by rubber chains from a bar insulated from the bracket arm. The bar below the bridle wire is connected to the metal pole and thence to the rails. In case of the failure and breakage of one of the suspension wires, it would touch this earthed bar, producing a short circuit and throwing out the circuit breaker protecting the line. It can be seen from this that with the double suspension system great safety is insured.

Telegraph and telephone wires passing over the trolley wire are completely surrounded by a wire cage which keeps them from coming into contact with the high tension line. In passing under the ordinary steel girder road bridges, the insulation must of necessity be perfect, in this case heavy insulators, mounted on a wooden framework, supporting the trolley wire.

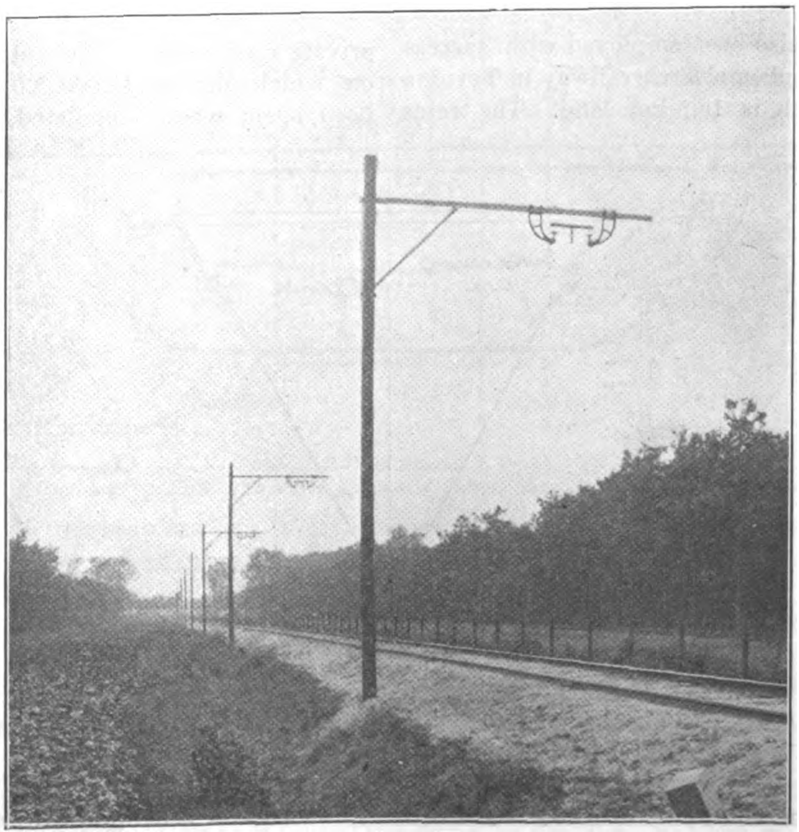

Fig. 2.—Single-Wire Suspension.

The cars are each provided with two motors whose power is rated at 100 to 120 hp. each. The two motors are mounted on the same truck and fitted with single reduction gearing whose ratio is 1 to 4.26. The Winter-Eichberg repulsion-series motor is used, and consists of a rotor and fixed stator. The rotor has a commutator and two pairs of brushes, the second of which, called the exciting brushes, is displaced 90 degrees from the first pair, which coincide with the axis of the magnetic field and are short-circuited. The exciting brushes are connected to the secondary of a transformer, the primary of which is in series with the high tension stator. The use of a transformer enables a high pressure to be used in the fields while a low pressure can be used in the armature winding.

The handle of the master controller is supplied with a push button which must be kept pressed down by the motorman. In case of accident to the driver or should he let go the handle for any reason, the motor is brought to a standstill and the motor handle will go back to the off position and put on the air brakes.

The master and reversing controllers have but a small current of low voltage and all high tension apparatus is arranged in such a way as to insure the highest degree of safety to the motorman, conductor and passengers. Compressed air is used to raise and lower the trolley from the wire.

The Winter-Eichberg single-phase system has also been employed with success on the Stuben electric railway in Tyrol, a line which is 18.5 km. long. The trains in this case consist of one motor car and two trailers. The tension is 2,500 volts and the frequency 42 cycles per second.

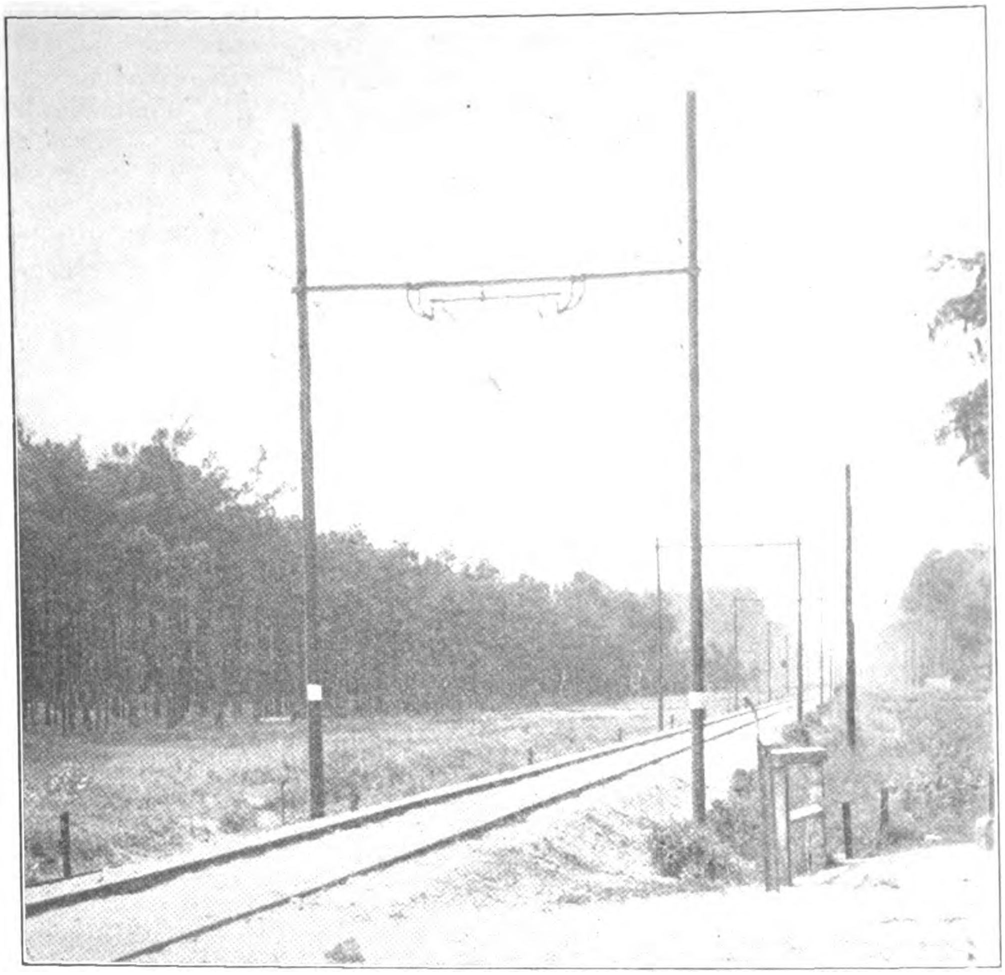

Fig. 3.—Double Suspension Wire Construction.

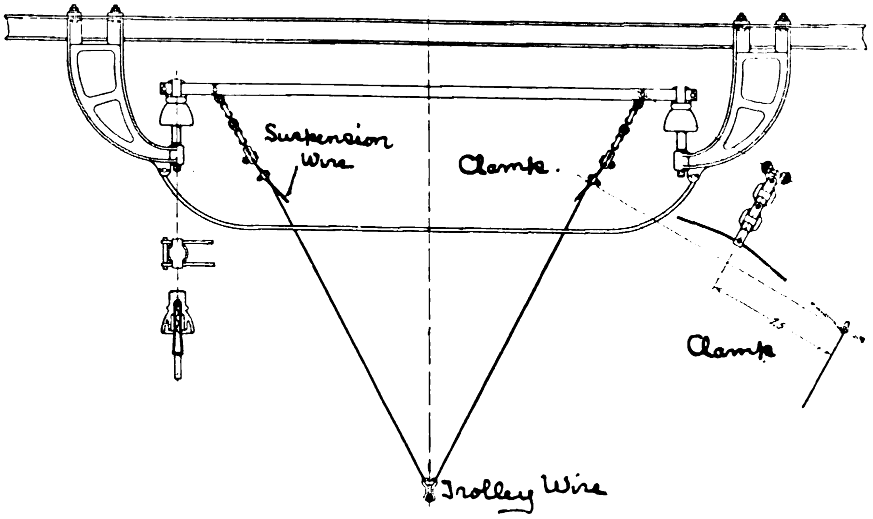

Fig. 4.

Manila's Electric Railway System.

It is announced that the electric railway system in Manila is near completion and that the road will probably be in operation by April 1. About 40 miles of track have been laid and a large electric plant erected, which in addition to supplying motive power for the car lines will also furnish lighting to the city and private consumers. The entire project, on which almost $2,000,000 will have been spent when completed, has been done with American capital, and practically all the equipment and material used is of American manufacture.

Pisa's Wireless Station.

The largest station for receiving and transmitting wireless messages is being erected near Pisa, Italy. On its completion, by the end of the year, it is expected to afford direct communication with all countries of Europe, as well as the United States and Canada, and with all vessels on the Mediterranean, Indian and Atlantic Oceans.

ELECTRICITY LEAFLETS.

BY NEWTON HARRISON, E. E.

THE MOTOR.

Conditions of Service.—The two broad classifications of motors, as far as service is concerned, may be termed the motor for stationary and the motor for vehicle purposes. Stationary service may be still further divided so as to represent all those included under that head such as

STATIONARY SERVICE.

Factory drive, all kinds.
Ventilation, including fan motors.
Hoisting and elevator service.
Mining, such as drilling, etc.

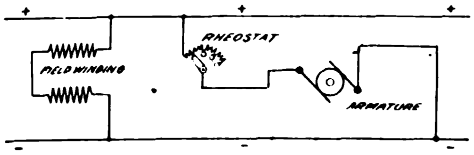
The conditions of service for stationary motors may be extended so as to include applications of less importance, such as dental apparatus, medical appliances, stage devices, etc. The other list of conditions of service, in which the motor is employed for transportation from point to point is as follows:

TRANSPORTATION SERVICE.

Electric railway work.
Automobile work.
Launch work.
Agricultural work.
Mining work.

Depending upon the nature of the application of the motor to any specific purpose, the character of the motor itself is determined. This is the influence which gives rise to the employment of series, shunt or differentially wound machines taking a direct current or the installation of motors taking an alternating current.

Starting a Motor.—To start a motor from a condition of rest requires the employment of a device which will not permit more than the proper quota of current to pass through. In a series motor a resistance interposed between the line and itself will prove sufficient. In a shunt motor it is necessary to take certain precautions in this direction, so as to limit the flow of current through the armature. Enough time must elapse from the moment the current is turned on until the resistance is cut out, to permit the armature to develop sufficient back electro-motive force to act as a restraining influence upon the current. The correct function, therefore, of the resistance is to act as a substitute for the back EMF. It must be remembered that the field windings of a shunt motor are connected across the line and take their energy directly from the circuit. The armature will be connected in the same way *after* the motor is running. But until the motor is developing enough back EMF., a resistance is kept in series with it,



Before Motor is up to speed, Starting Box and Armature in Series.

that is, the armature; and only when the speed is high is it deemed safe to gradually cut it out. It is thus evident that both field and armature are in multiple with the line receiving the full pressure, but the armature is protected from an overplus of current when starting, by a resistance in series. The resistance must, therefore, be estimated with respect to these conditions. Suppose, for instance, that an armature of .02 of an ohm is to be put in series with a resistance. A 110 volt current would tend to send in 110 ÷ .02 = 5,500 amperes, which would spell ruination to the machine if such an immense current could enter. Aside from the protective devices employed to prevent just such a catastrophe to the motor, the resistance inserted must bear a definite relationship to the capacity or horse power. Resistances are therefore termed 110 volt 2 hp. resistance boxes or rheostats, or as they are frequently called, "starting boxes." Now in the case under consideration, if the back EMF. of the motor equals 109 volts, the pressure of 1 volt will operate on an armature resistance of .02 ohms, sending through 50 amperes at full load.

If a resistance box of from 10 to 20 ohms is selected, to put in circuit with the armature, then, even though the armature does not revolve very fast only 5 or 10 amperes can get through in the beginning, and the danger of a short circuit is removed. After the armature speeds up, however, the resistance is cut out, the back EMF. bringing about the proper adjustment between the load and the current consumption. The resistance of the starting box is determined, therefore, with respect to the total current the motor will take; its horse power in fact, and it is made adequate enough to limit the flow. It is best to understand that the current a motor takes is largely, if not entirely, a question of its efficiency. For instance, a 10 hp. motor will take a theoretical current of 74.6. amperes at 100 volts pressure. The total watts are 10 × 746 = 7,460; but if the efficiency of the motor is not high, it will take more watts in proportion, which at the line pressure would mean more current. The amount of current required by a series of motors of 10 hp. apiece at varying efficiencies is given below:

Volts.	Horse power	Efficiency.	Total watts consumed.	Amperes.
220	10	100 %	7,460	34.0
"	"	90 "	8,289	37.7
"	"	80 "	9,325	42.4
"	"	70 "	10,657	48.4
"	"	60 "	12,433	56.5
"	"	50 "	14,920	68.0

This table is exceedingly instructive in showing the relationship between efficiency and the consumption of power. It is not difficult to estimate that a motor of low efficiency, will waste in a certain period of time, an amount of power, the cost of which will compare readily with its own cost. In other words, if a motor is cheap because its construction makes it inefficient, it is for that very reason dear, because its power consumption makes it expensive. If a motor costing $100, wastes $10 worth of power a year, in 10 years it eats up its own cost. If it wastes $20 worth a year, 5 years will eat up its own cost, etc. A high efficiency motor is therefore cheapest, though its first cost may be greater. Another point of great interest is that of speed. Small power users are peculiarly addicted to the habit of overloading motors. Jacobi many years ago enunciated the principle that a motor is doing its maximum work, when its speed is one-half its normal speed through being loaded down. At this rate of speed and load, it has only 50 per cent. efficiency. It is therefore consuming twice as much power as it should, and the cost of operation is doubled. While this is true, that a motor can do more work if overloaded, it does that extra work beyond its capacity on a very wasteful basis.

It is not wise, therefore, to place a strain beyond the normal rating upon any motor, unless it be for the purpose of bridging over an emergency for a short period of time. Speed, back EMF., load and line pressure are so related, that they all contribute to the common result of high or low efficiency.

MOTOR

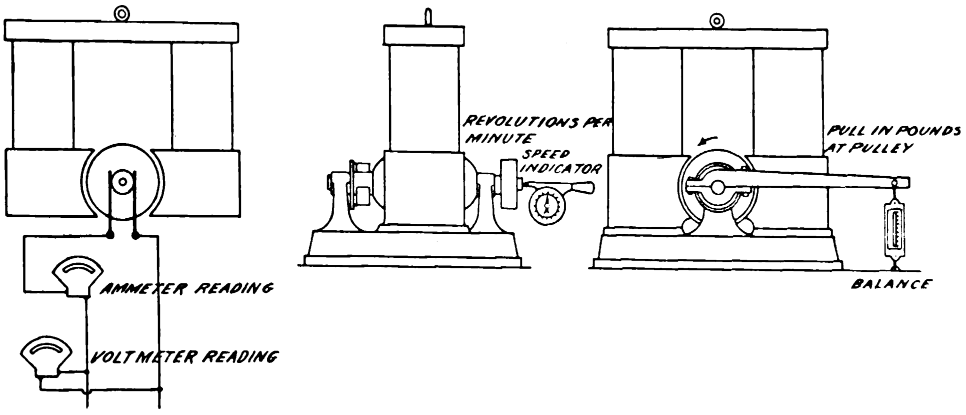
Protection of Motors with Single and Double Pole Circuit Breakers.

Circuit Breakers in Motor Service.—The possibilities of sudden overload with the resulting inrush of current have been the means of introducing the circuit breaker, or electro-magnetic switch for the protection of motor as well as dynamo lines. The electro-magnet, and switch, of which it is composed, are simple enough in general construction, but the electro-magnet must be sensitive to a certain value of current; so that if this point is passed it will be the means by which the switch flies open and disconnects the motor from the line. The switch is so constructed that when it flies open its action is sudden and arc-less. The circuit breaker is a substitute for the old time fuse, whose dangerous volatilization was an ever present risk of fire during a temporary short circuit. Motor and dynamo circuits protected with this particular device are like boilers supplied with safety valves weighted to a certain number of pounds. In one case steam pressure will set the valve into sudden operation, in the other case an overflow of current.

A line connecting to either a motor or generator may be protected by the installation of a single pole or a double pole circuit breaker. By this is meant a circuit breaker, which is inserted in only one leg of the line involving a single pole, or one engaging both wires or poles, hence the title double pole.



Readings of an Electrical and Mechanical nature to make a Commercial Efficiency Test of a Motor.

Rating of Circuit Breakers.—In order to convey some idea of the development that has taken place in this particular department of electrical manufacturing, the following table of rating and calibration is given for circuit breakers of from 5 to 1,500 amperes They are of a standard market type, double pole, for from 250 volts or less, and one type so constructed that if during the short circuit or overload of the motor which originally operated the circuit breaker, an attempt is made to close the circuit again, only one pole at a time can be closed. If one has been closed and the other is then set, the first will fly open independently, thus freeing the line and protecting the operator from injurious flashes:

Low Load.		Heavy Load.	
Normal Rating.	Calibration.	Normal Rating.	Calibration.
5	4 to 8	200	150 to 300
10	8 " 15	300	225 " 450
20	15 " 30	400	300 " 600
30	25 " 45	500	375 " 750
45	35 " 70	600	450 " 900
60	45 " 90	800	600 " 1200
80	60 " 120	1,000	800 " 1500
100	75 " 150	1,250	900 " 1800
150	110 " 225	1,500	1200 " 2250
200	150 " 300		
300	225 " 450		

Commercial Efficiency.—The rating of motors for commercial efficiency is based upon the tests to which they are subjected. The tests are simple in character and may be defined as a method of establishing the ratio between the power taken out in a mechanical form to the power sent in, in an electrical form:

$$\text{Commercial efficiency} = \frac{\text{mechanical energy obtained}}{\text{electrical energy supplied}}$$

The motor is supplied with an ammeter and voltmeter to measure the electrical energy sent in. A tachometer or speed meter is utilized for getting the number of rotations of the armature per minute. A dynamometer or brake is used for measuring the pull on the pulley or shaft of the motor. If the pull on the dynamometer or brake is taken at a certain rate of speed, it will be accompanied by a certain current consumption, the voltage remaining the same. This data is serviceable for determining the efficiency as follows:

$$\text{Mechanical hp.} = \frac{\text{Pull in pounds} \times \text{length of brake arm in feet} \times \text{speed per minute}}{33{,}000}$$

$$\text{Electrical hp.} = \frac{\text{Amperes} \times \text{volts}}{746}$$

$$\text{Efficiency} = \frac{\text{Mechanical hp.}}{\text{Electrical hp.}}$$

The efficiency is obtained in this manner for all such points of load as running idle, quarter load, half load, three-quarter load and full load. The speed, amperes and pull will vary in each case, the amperes and pull naturally very much more than the speed, which should not indicate serious changes.

PATTERN MAKING.*

BY R. WATSON.

Twenty or thirty years ago pattern making and mill wrighting were considered joint branches of engineering, but gradually as competition and more complicated work came along, it was found that a man, to become thoroughly efficient, must devote his whole time to one branch. This subdivision has again taken place in the pattern shop of recent years. Iron pattern making has become quite a separate section. This includes the fitting up of iron patterns, turnover plates, and all stripping plates, etc., required for moulding machines. Again, where moulding machines are used men are kept on the special patterns that are required for them until they become quite experts at this class of work.

It is not the writer's intention to deal with these special kinds of patterns; each is important enough in itself to form a separate paper, but to confine himself to his actual experience of wood patterns. It may be well to consider the material used in pattern making. Timber merchants have at various times advised several different kinds of wood, such as kauri pine, American white wood, teak and jarrah, etc., but experience has proved that they are not as suitable for pattern construction as Canadian pine and the mild straight-grained mahogany of Tabasco and Belize. Timber for standard patterns should be carefully selected as there is a considerable variation in the quality of yellow pine. It is not unusual to find a shipment of pine altogether unsuitable for pattern making. It may be free from shakes and knots but has the defect of being hard in places, which is known to the pattern maker as being "strong."

The circular saw, band saw, planing machine, thickness planer and lathes are indispensable tools. The hand trimmer might also be classed among them, for it

---

*Abstract of paper read before the Rugby (Eng.) Engineering Society, Jan. 5, 1905.

considerably cheapens the production of patterns, especially of that class which are built up in segments. The introduction of pneumatic tools into the pattern shop is among the latest labor-saving devices. Portable drills and chipping hammers are finding a useful place on large work; they have this advantage, that they can be brought right on the work during the different stages of construction when it would be impossible to move the work to the different machines. Chipping hammers fitted with a gouge tool are very handy for removing surplus wood to form curved surfaces in patterns and core boxes, doing the work from four to six times faster than is possible with hand tools. Pneumatic drills also dispense with the pattern maker's brace and bit and perform the work very rapidly and with considerably less labor to the man.

It is in the pattern shop that the engineer and draughtsman first see the actual thing which they have designed. Many views and sections may be given, but there still remain points which have to be left to the judgment of the pattern maker, such as the development of curves, rounded edges, fillets, etc., all of which go to make the symmetry of the whole. Upon receiving a drawing in the pattern shop, if the work is at all complicated, it is set out full size, but in some cases sections only that are required for the construction of the pattern and arrangement of cores. Machining allowances are shown. All the setting out is done to a contraction rule, so that any dimension may be taken as the pattern size.

In some works the foreman or leading hand sets the work out. The writer prefers that each pattern maker should set out his own work, as by so doing he makes himself familiar with all the details. He is then in a position to discuss the construction of the pattern, method of moulding, and arrangement of cores. It is usual for the principle dimensions to be checked by the foreman. The first thing that has to be determined is the best way of moulding, and if it is likely to be a permanent or temporary pattern. The chief things that govern the moulding are the principal machined surfaces; these are placed in the bottom of the mould to insure them being clean and free from defects. If it has to be machined all over, or top and bottom, extra machining should be allowed on the top side.

Patterns should in all cases where possible be parted and doweled together on the joint line of the mould, as in the case of a cylinder through the center line of the circle, so that when the top part of the moulding box is lifted off, the portion of the pattern covered by it is taken with it. Then the moulder can loosen each part separately and see what he is doing in drawing the pattern from the mould. It is advisable to lift the pattern from the mould rather than the mould from the pattern. If the moulding box has to be lifted off, leaving the pattern behind, it often results in some portion of the mould breaking down, which sometimes costs a large amount of time to repair.

Loose pieces, such as bosses and facings, although objectionable, cannot in all cases be avoided On permanent patterns these should be fixed on by a dovetail. On temporary patterns a screw or wire pin will do, providing the position of the piece is well scribbed round on the body of the pattern. Where several pieces have to be loose near each other, it is as well to leave one large piece of the pattern loose containing them all, providing there is sufficient room in the mould to allow this being drawn in. Another method of getting over the difficulty of several loose pieces is to put them all together in a core. The objection to this is that in dry sand work it often leaves a mark on the casting if the core cannot be put in green and dried with the mould.

In constructing large patterns wide pieces of timber should be avoided because of the shrinkage and expansion. Frames made of narrow pieces and half lapped together at the corners can often be used with advantage. These are stronger and retain their shape better than large flat pieces. There is also a considerable saving of timber by this method. Patterns made of dry timber will expand when left in the mould for any length of time and contract when stored away. In boarding up large surfaces, open joints, say $\frac{1}{8}$ in. between each joint, should be left. All screw holes should be bored larger than the diameter of the screw to allow free movement when the boards expand or contract.

Where possible the grain of the wood should run in the direction that the pattern is going to be drawn from the mould. As little end grain as possible should be left exposed to the sand. If it cannot be avoided it should be placed so that it is the first portion of the pattern which leaves the mould when it is drawn out. If it is in the bottom of the mould the other way of the grain will shrink and leave the end grain projecting, which will pull a part of the mould up when the pattern is drawn out. This is often the cause of the moulder having to do a considerable amount of sleaking to the mould.

In large patterns, such as bedplates, etc., good provision should be made for rapping and lifting, as it adds considerably to the life of the pattern. In the joint or side of the pattern from which it is going to be lifted from the mould, stout timbers should be put in to receive rapping plates, connected to the bottom of the pattern by struts or stays. Lifting bolts or straps should go through the body of the pattern. In cases where bolts are used there should be a plate let in level with the bottom of the pattern and screwed to receive the bolt. Where this system is practiced it is usual to have all lifting plates screwed one size, then one bolt will do service for several patterns. The screwed end of the bolt should be well tapered off to give it a lead into the bottom plate. The top end should have an eye at least 2 in. in diameter, so that it will receive the hooks which are in general use around this class of work in the foundry. There is a certain amount of suction in lifting a pattern from the mould in addition to the weight of the pattern itself. Then there is the question of taking the pattern backwards and forwards to the pattern stores. If lifting irons can be relied upon, it is better to lift by them than by rope or chain slings, for these generally leave their mark on the pattern. In fact, heavy standard patterns are often more damaged in lifting about than in actual use in the foundry.

The question of taper is often a very debatable subject between the pattern maker and moulder. It is seldom the moulder complains of there being too much, but excess of taper often means more machinery than is necessary. There is no standard rule; each piece of work requires separate consideration. In most cases $\frac{1}{8}$ in. to the foot is found to be sufficient. On castings that have not to be machined it is customary to make the given dimensions half-way down the pattern, so that the pattern at the top of the mould is over the size and at the bottom under the size.

In complicated patterns sometimes pieces are left so that the moulder has to lift a part of the mould away before he can draw the pattern out, or, in other words, make a "drawback." This is an expensive method to the foundry. It can often be overcome by a core print being put on the pattern and a box made to suit. It incurs extra cost in making the pattern; still this fact should not be lost sight of, that it only has to be done once in the pattern shop, but every time a casting is made off the pattern in the foundry. If this extra cost is divided by the number of castings required, it will be readily seen that the "print and core box" is often the cheaper method to produce the casting; for this should be the aim of the combined efforts of both pattern maker and moulder. Where the core method is used great care must be taken that the piece which forms the part of the core matches the mould; if it is possible this piece should be worked on the pattern in its place, then taken off and put into the core box. This will ensure getting a good joint and only a very slight mark on the casting.

Prints that lift vertically should have more taper than other parts of the pattern. In no case should the taper be less than ⅛ in. to the inch. The size of the core is the size of the print near the pattern. In prints where the core comes through the top moulding box for convenience of centering or releasing the core, etc., the size of the print is still kept the right size near the pattern, but tapered larger to give clearance for passing the core down, as shown in Fig. 1. No two prints on a pattern should be the same size, or nearly the same size, or probably the mould will be cored up wrong. In prints that mould horizontally the root should have a slight champher on it, as shown in Fig. 2, as the edge of the mould breaking down when the core is put in. If this is not done the moulder generally takes it off with his trowel each time he makes a mould.

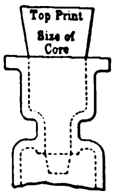


FIG. 1.

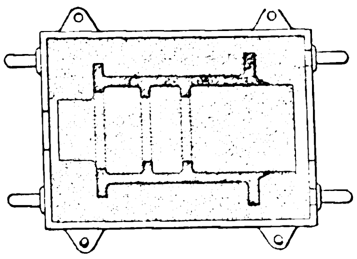

FIG. 2.

Cores are often more difficult than the outside of the pattern; it often takes considerable time to arrange them so that they may be put in the mould in the readiest possible way. Circular core boxes are generally doweled together on the center line for convenience of ramming up and getting the core out of the box. Intricate boxes often have to be made in several parts; where any doubt exists as to the best way of making it, the core maker should be consulted as to the handiest way for him to arrange for his core irons and vent passages. Large sized boxes should be made so that they can be taken to pieces, and the corners rabbeted together so as to insure them being put together in the same place, and not trusting entirely to the screws going in the same holes. In boxes for standard work wood screws should not be used, as the constant taking them in and out wears the holes, and the core is made larger than required. Bolts should be used for screwing the boxes together with suitable shaped handles or wing nuts. These are more quickly released than wood screws and soon saves the extra cost. In no case should the ordinary hexagon nut be used, as the time that should be saved is lost in hunting for a spanner of the right size.

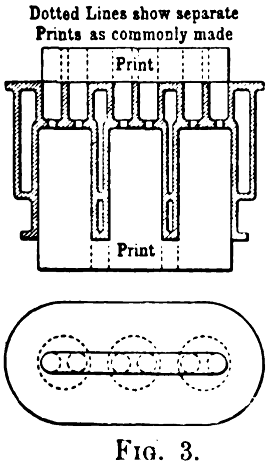

FIG. 3.

In large cores allowance has to be made for the expansion of them in drying; 1-16 in. to the foot is found sufficient if the cores are dried at the usual rate. This point (which is not recognized by some pattern makers and moulders) is often the cause of considerable delay due to the time taken in rubbing the cores down to give the required thickness of metal. After the core has been dried the best test is to try and place it in the box in which it has been made. It is accounted for by the core iron expanding while the core is being dried, and pushing the sand out with it. The core iron contracts in cooling, but the sand on the outside of the iron is baked hard and does not move back with it.

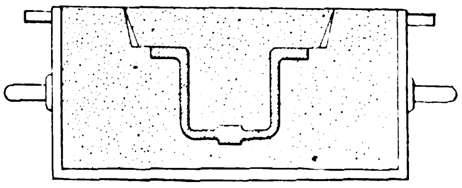

FIG. 4.

Large cores should where possible be made the same way up as they are to be put into the mould, for convenience of getting at the iron to lift them by when fixing.

Where cores have to bore out to exact centers in relation to each other, as in the case of motor cylinders, where two or three boxes are in the same casting, these should be made in one core box tied together by continuous prints at both ends, as shown in Fig. 3. This admits of a good stiff core iron which can readily be broken without any risk of breaking the casting. It is a quick method of coring up, as all the bore cores are put in at one operation, as well as keeping their centers exact, at the same time simplifying the moulding of the pattern.

Where diaphragms, valve facings, etc., on the inside of the casting, have to be put in a particular position in relation to the outside of the casting, a key must be put on the core and its print. This should be put on the joint of the mould where it can be seen when coring up. It is often found useful to make the print on the pattern smaller than the required size of the core, so as to form a shoulder on the core, as shown in Fig. 2. The core can then be put up to the end of the mould; this will give it a definite position lengthways independent of the ends of the print, from which the moulder often finds it convenient to cut the sand away. This shoulder should be made in proportion to the size of the core; it must not be less than ⅜ in., increasing up to 1½ in. in large cores. If it is made too small it will get a thick coat of blacking and do more harm than good. In small cores where great accuracy is required and where the metal is very thin the core should be made about 1-32 in. smaller in size than is required, to allow for blacking, and care must be taken that the cores fit their prints, for when once rubbing is commenced on the core no two castings will be identical. In this class of work the first casting that is made off a pattern should be cut up to see that all parts are of the required thickness.

Core boxes that are made to suit taper prints should be the exact size at the point where the casting commences, but should be slightly less than the top of the print; this will insure them going in easily and tightening themselves when they are down in their right position. Core boards that are to be used for cores of which large quantities are likely to be required should have a thin sheet of iron on the striking edge, filed to the exact shape of the board, on the top side two strips of iron should be screwed on, giving the exact size of the prints into which the core is to fit, otherwise after a few cores have been made the board gets worn and often gives considerable trouble both to the moulder and machinist.

Large work, such as condensers, flywheels, pipes, etc., are usually swept up in loam, very little pattern making being required, as loam boards are used to make both the inside and outside, all projections having to be built in the mould. Work of this type is usually cast upon end. These do not contract the ordinary amount, 1-200 in. to the foot is found to be sufficient to allow in this class of work. Loam work as a rule takes more time in the foundry than when a pattern is used. No doubt it is the correct method to follow when two or three castings only are required, but when this amount is exceeded the cost of a light skeleton pattern, against the extra time each casting will take to make, should be considered. A case of this kind was given in the "American Foundry Journal" some time ago, where an American company had six sets of large engine castings to make, the first one or two of each of the larger pieces were stuck up. Afterwards it was decided to make patterns and moulding boxes to suit. In finishing the remainder it was found to be both cheaper and quicker and the castings better to shape. This question is often settled by the tackle that exists in the foundry, for plates, binders, etc., required for loam work are expensive items. Another way of handling work of which only one or two castings are required is to make the outside in cores. This can often be done very economically, for one or two core-box shells with different internal fittings may be made to do duty for all the cores required. This method cuts the pattern making down to a minimum. In large work of this class especially, the pattern maker and moulder should try to avoid getting into set grooves of working, for the method has yet to be found that is economical and suitable for all work.

Light castings, such as covers, caps, cone pulleys, etc., may be made so that the core takes the place of the top moulding box and is self-centering, as shown in Fig. 4. This core must be at least 1½ in. thick and 1 in. larger all round than the casting, so that it will bear sufficient weight being placed on it to withstand the lift while the mould is being poured. The print should have a large taper; this makes it simpler both for moulding and coring up. It is important in this method of work that the core fits its print, and that no blacking is put on that portion of the core which goes into the print. Patterns of this description, if they are circular, should be built up in segments, or framed up if square.

All circular work on standard patterns larger than about 10 in. diameter should be build up in segments; it has the advantages of being stronger, does not shirk or expand, and retains its shape better than when cut out of the solid wood. The "trimming machines" now used in most pattern shops have cheapened this class of work. Built up work often can be made to leave its own core with advantage, and so save the time and material that would otherwise be spent in making a core box. The writer does not recommend building up flanges, etc., in less than three courses; in fact, two courses are very little better than when cut out of the solid. In pipes, cylinders, etc., "lagging up" is resorted to when the diameter of the work is large, partly to economize material and to secure a form which will be least affected by the distorting influence of shrinkage and expansion. Lags are usually made from 3 in. to 5 in. wide and the number that go to make up a diameter is determined by the size which can be cut most economically out of the width of a plank. In large diameters the rings on which the lags are fixed are built up in segments; this makes a very light but rigid pattern. This method of lagging up is not confined to circular work only, but is used on curves wherever a radial line can be fixed. There is often a difference of opinion as regards the right amount of contraction to allow on special large work, but the writer thinks that most people are fairly well agreed that for general castings 1 in 120 is found to give the most reliable results and most pattern-makers' rules are now made to this allowance. Steel and malleable iron of different makers often vary much in the contraction. In large size castings in these metals the safest way is to ask the founder what contraction should be allowed; on small work the following data can generally be relied upon: General iron $\frac{1}{120}$, loam work cast vertically $\frac{1}{200}$, brass $\frac{1}{64}$, phosphor bronze $\frac{1}{100}$, steel $\frac{1}{48}$, aluminum $\frac{1}{74}$, malleable iron $\frac{1}{64}$ and lead $\frac{1}{48}$.

Painting and Varnishing of Patterns.—Various opinions are held by pattern makers on this subject, but all agree that patterns, except those of the most temporary kind, should be painted or varnished, as it preserves the pattern and fills up the grain of the wood, so that the sand does not cling to it when the pattern is being withdrawn from the mould. One good method that is practiced by some of the larger firms is to paint "black" parts that are not to be machined, "yellow" parts that are machined, and "red" for prints and parts where the core cuts through the metal. In parted patterns the section is painted in the joint. This method enables the moulder to see at once what parts are going to be machined. It also shows him the arrangement of the cores and the thickness of metal, so that he can see where to cut the runner gates to the best advantage, without having to correspond the core boxes with the pattern, thus saving the time which would be taken in doing so. It also assists the pattern storekeeper in getting out the different core boxes belonging to a pattern without having to refer to his book or getting the tracing to see how many core boxes are required.

Upon finishing a pattern all center lines should be cut in deeply with a scriber; this makes it much quicker to check the pattern, and also to make any alterations to it, as most of the principal dimensions are given from the center lines.

Makers of different kinds of machinery have a system of marking their patterns best suited to their own class of work. Standard patterns generally have the marks cast on in raised letters or figures; this mark should also be stamped plainly on the pattern, core boxes, and all loose pieces that are used with it. A method that is now being employed for small patterns is to have the "pattern mark" stamped on a piece of aluminum by an automatic machine; this gives a fairly good mark on the casting if a little extra care is taken by the moulder.

In conclusion, it may be well to add that in making patterns they must not be considered finished articles, but as means which are employed to produce castings. With this aim in view the work should be so distributed between the pattern shop and foundry that upon receipt of an order for castings it will result in their delivery with economical dispatch.

SERIES ALTERNATING ARC LIGHTING.*

BY E. P. WARNER.

(Continued from page 140.)

OUTSIDE CONSTRUCTION DETAILS.

One of the most prolific sources of trouble on outside construction work lies in the lamp suspensions. Where lamps are suspended from span wires crossing the street, it is not uncommon to find a very poor insulator interposed between the lamp and the span wire. This often puts the full strain of the extreme voltage of the system between a lamp and the suspension wire to ground. Heavy leakage and general low line insulation is the result of such construction. In many cases the line loop extending from the pole to the lamp is brought to a small wooden cross-arm equipped with small porcelain knob insulators at each end, and from there extends downward to the terminals of the lamp, which is in turn insulated from the small wooden cross-arm by a single porcelain insulator, the cross-bar itself being practically uninsulated from the span wire when the lamp is hoisted into position. Under these conditions the line insulation is secured only by the small porcelain knobs at the end of the cross-bar and the surface of the cross-bar itself, which in ordinarily stormy weather is entirely insufficient. Under the conditions described the lamp itself is also subjected to severe strain by reason of its insufficient insulation from ground. It is all very well to say that a series alternating arc lamp should be able to withstand a breakdown test to ground without damage to the insulation of 7,000 to 8,000 volts alternating current applied for one minute, but it has been demonstrated in practice that lamps which will stand this breakdown test when new and clean will fall very short of it after but a short period of actual service. The only practical way of securing good line insulation is to place a thoroughly good insulator above the lamp and above the cross-arm, if one is used, so that the line itself, as well as the lamp, will be insulated from the span wire. Under such conditions the necessity for any high voltage test between the live parts of a lamp and the case is done away with and is, in fact, undesirable. No superintendent of a station, who has proper regard for the safety of the lives of his employes, will permit them to handle a live lamp while standing on the ground and no matter what breakdown test a lamp may be said to stand the employe should not place reliance on it, but should as thoroughly insulate himself from ground as though the lamp were alive in all parts.

---

* Paper read at the 13th annual convention of the Northwestern Electrical Association, held at Milwaukee, Wis., Jan. 18-20, 1905.

Again, the argument may be raised that there is liability of the lamp coming in contact with some other wire and thus grounding the case. I think there are very few of you who will fail to realize that this is a very remote contingency indeed, and you will also realize that a break-down test such as that outlined above would fall very short of preventing trouble in such a case, particularly after the lamps have been in service for some time.

ARC LAMPS.

In the early stages of development of the different series alternating systems, certain manufacturers attempted to make use of arc lamps in which the regulation was controlled entirely by shunt winding, claiming that by using such a lamp they were enabled to secure very high efficiency with sufficiently good regulation. As time passed on lamps of this type were gradually eliminated from the field, and as an illustration of the survival of the fittest, we have to-day practically only the differential type of lamp, the shunt controlled being a failure.

Now a few words as to the desirable features in the series alternating arc lamp:

1. It must be one in which the operating parts are few and of such design and construction that stock repair parts can be used in repair with facility and dispatch.

2. The parts should be so assembled and attached as to facilitate removal and replacement, also to give ready access for examination and adjustment.

3. All material used should be of a character to best resist the action of the elements and ordinary wear and tear encountered in actual service. The quality of material used and its application should be a matter of careful scrutiny to the station manager, as therein lies part of the secret of reliable and continuous service. Do not let first cost be the prime factor in your choice of a lamp.

4. Regarding the performance of the lamp and the safeguards provided, I would say that it should be capable of regulating the voltage of the arc to the point adjusted within three volts in either direction, and when operated with a current of 7½ amperes should give a life with each trimming of approximately 90 hours.

It is found in practice that variation in the sizes of the carbons, in the character of the core, in the density of the material used in the carbons, will considerably effect the length of life. This means that care should be taken in selecting carbons, though I think no greater amount is necessary than has been found to be the case with old open arc systems. In all lamp mechanisms there is a certain amount of lost energy; in a well constructed lamp this loss should not greatly exceed 20 watts. The efficiency may vary somewhat with the different makes of carbons and the different stages of the burning, but the figures given above are a fair general average. The power factor of an arc lamp varies with the quality of the carbons, with the position of the arc in the globe and also with the character of the cored material. It has been found possible in experimental practice to maintain an alternating arc using two cored carbons of very rich material at unity power factor, but such results have not as yet been obtained commercially. With the ordinary carbons obtainable to-day, a general average power factor of 90 per cent. in the arc can be obtained reliably. In estimating this power factor we find the ratio of ~~the~~ true watts at the arc to the apparent watts. It has not been customary for purchasers to specify any stated performance in respect to the power factor of the arc; they have contented themselves with the power factor of the lamp as a whole. This, of course, is somewhat lower than the power factor of the arc, varying in different makes of lamps. It is, however, a very important feature which must be considered by the purchaser and he should be careful to exact definite performance in this respect.

(To be continued.)

Lehigh University Register.

The Register of Lehigh University, South Bethlehem, Pa., just issued, copies of which may be had on application, shows the attendance of 630 students from 24 States and 8 foreign countries, the largest in the history of the institution. There are 56 in the teaching staff; 92 students are taking the course in electrical engineering.

Thirteen four-year courses of instruction are offered at the University: the Classical Course, the Latin-Scientific Course, the courses in Civil, Mechanical, Marine, Metallurgical, Mining, Electrical, and Chemical Engineering, Analytical Chemistry, Geology, Physics, and Electrometallurgy.

A list of graduates of the University, with their present occupations, 1,399 in number during the 39 years of its existence, indicates that this institution is exerting a marked influence on the industrial development of the United States and of foreign countries.

Provision is made for worthy and needy students whereby they may postpone payment of tuition until after graduation.

Important Catalogue Just Issued.

The 1905 catalogue of the Waterbury Brass Company, Waterbury, Conn., has just come from the printer's hands. We are informed that the catalogue has the complete tables and weights of seamless, drawn, brass and copper tubes and brazed tubes and brass and copper in rod, wire and sheets, also tables which are short cuts in arriving at certain results in figuring inside and outside diameters of seamless tubes for the weights and also in connection with rod, wire and sheet in brass and copper, and a very valuable table of discounts. In connection with this is given a complete list of the stock carried at the Waterbury warehouse and also at the Providence warehouse.

Claim that Chicago Telephone Company is Disobeying the Law.

On the ground that the Chicago Telephone Company is violating its ordinance the city authorities will attempt to compel it to obey the law or drive it out of business. It is claimed that the company by its failure to make semi-annual reports of its receipts, and its practice of collecting tolls in addition to its regular charges in certain districts within the city limits, has forfeited its franchise. Corporation Counsel Tolman has filed a petition with State Attorney Healy asking permission to institute proceedings to test the company's right to continue to operate its lines in the streets of Chicago.

Lectures Before the Society of Engineers of the University of Minnesota.

Mr. Fred. G. Dustin, city electrical inspector for Minneapolis, gave an interesting lecture on February 24 before the Society of Engineers of the University of Minnesota on "Safety in Electrical Installation." After describing the development of the present insurance rules through the co-operation of the electrical and insurance organization he took up the city ordinance governing electrical installation and operation. To illustrate the necessity for certain rules, he showed interesting samples of defective fittings and construction which he had condemned. Samples of new devices showed how new rules are being met. Among other instances of improper operation, he noted an instance where the only fuse in the circuit had been replaced by a tenpenny nail. In closing, he admonished the young engineers to supplement their theoretical work with practical experience, emphasizing that their ultimate success or failure would depend upon their ability to put into practical use the technical training and knowledge they were acquiring.

On March 24, Mr. Benj. Waller, resident engineer of the Northwestern Telephone Exchange Company, will lecture upon "Some Engineering Features of a Modern Telephone Exchange."

New York Electrical Society.

The 249th meeting of the Society will be held at the lecture room of the American Institute, 19 West 44th street, this (Wednesday) evening, March 15, at 8 o'clock. Dr. E. F. Roeber, editor of "Electrochemical and Metallurgical Industry," will lecture on "Recent Developments in the Electrometallurgy of Iron and Steel." The meeting will also be addressed by the well-known authority Dr. Paul L. T. Heroult, of La Praz, France, on "Making and Refining Steel in the Electric Furnace." This subject has been attracting a great deal of attention in the fields of electricity, metallurgy and mining, and the successful solution of the problems involved may revolutionize the iron and steel arts.

Competition for Furnishing Electrical Supplies.

The annual competition for furnishing the executive departments at Washington with electrical supplies during the fiscal year 1906, will take place May 4 next, on which day bids will be opened in all the departments. Specifications and lists of articles required are now being prepared and the call for bids will be issued in ample time to allow prospective bidders to make their calculations.

Custom House Electrical Equipment.

James Knox Taylor, supervising architect, will receive proposals until May 8 for the interior furnishing of the United States Custom House in New York.

PERSONAL MENTION.

Prof. Lucien I. Blake, one of the earliest inventors in submarine signaling, has become associated with the Submarine Signal Company as consulting engineer.

Mr. W. J. Chalmers, vice-president of the Allis-Chalmers Company, has resigned, and it is likely that the headquarters of the concern will now be moved from Chicago to New York. Mr. W. H. Whiteside, former superintendent of the sales department, succeeds to the vice-presidency.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED MARCH 7, 1905.

Electric Railways and Appliances.

784,019. Electrically-Operated Station-Indicator. Ernest K. Adams, New York City; Edward Dean Adams executor of said Ernest K. Adams, deceased. Filed March 10, 1904.

784,037. Switch for Overhead Trolley-Tracks. Robert N. Cundall, Hopedale. Mass., assignor to the Draper Company, same place. Filed Jan 4, 1905.

784,038. Automatic Self-Dropping Trolley-Pole. John Delane, Terra Haute, Ind. Filed Sept. 5, 1903.

784,139. Electrical Annunciator for Trolley-Cars. Ira J. Bradshaw, Waukegan, Ill., assignor of one-half to Jacob J. Dietmeyer, same place. Filed June 29, 1904.

784,237-238. Electrical-Rail Guard. Lewis B. Stillwell, Lakewood, N. J., and Frederick R. Slater, Yonkers, N. Y. Filed Sept. 16, 1904.

784,303. Third-Rail Electric-Railway System. Thomas J. Casey and Fred H. Pickles, New York City. Filed Aug. 11, 1904.

784,357. Circuit-Controller for Electric Railway Signals. Harry B. Snell, Jackson, Mich. Filed April 15, 1904.

784,448. Trolley. John H. Thompson, Charleston, W Va., assignor of one-half to Daniel Rogan, Birmingham, Ala. Filed Aug. 4, 1904.

784,522. Railway-Switch. Samuel R. Flowers, Richmond, Ky., assignor of part to William S. Hume and George W. Nelson, same place. Filed May 20, 1904.

Electric Lights and Appliances.

784,071. Electric-Lighting Apparatus for Railway-Cars. Willard F. Richards, Buffalo, and William A. Turbayne, Lancaster, N. Y., assignors, by mesne assignments, to the Gould Coupler Company, New York City. Filed April 4, 1904.

Electrical Machinery and Apparatus.

784,022. Electric Switch. Charles B. Askew, Chicago, Ill. Filed May 11, 1904.

784.032-102. Laminated Core and Brush-Holder for Dynamo-Electric Machines. James Burke, New York City, assignor to the Burke Electric Company. Filed March 9 and May 3, 1904.

784.056. Electric Motor. Waldo A. Layman, St. Louis, Mo. Filed Dec, 28, 1903. Renewed Aug. 25, 1904.

784,064. Electrically-Operated Locking Mechanism. John Nordenberg, Canon City, Col., assignor of one-half to Olof J. Rundahl, same place. Filed Sept. 16, 1904.

784,103. Dynamo-Electric Machine. James Burke, New York City, assignor to the Burke Electric Company. Filed July 18, 1904.

784,308. Electric Motor. George Dengler and Ida W. Schmidt, Detroit, Mich. Filed Sept. 12, 1904.

784,352. Power-Transmitting Device. Samuel W. Rushmore. Plainfield, N. J. Filed April 27, 1904.

784,358. Electric Time-Switch. Stanislaus Stemski, Brooklyn, N. Y. Filed April 12, 1904.

784.387. Electric Meter. Frederick Darlington, Great Barrington, Mass. Filed Oct. 13, 1904.

784,393. Commutator. Gustav Grabosch, Berlin, Germany. Filed July 30, 1904.

784,447. Means for Maintaining Synchronism in Electric Motors. Paul Thomas, Charlottenburg, Germany. Filed March 7, 1903.

784,456. Electromagnet and Armature. Joseph Weber, Brooklyn, N. Y. Filed May 1, 1900. Renewed Aug. 31, 1904.

784,471. Device for Forming Standard Elbows in Electric Conduits or Other Pipes. Lewis H. Church. Stamford, Conn. Filed Nov. 14, 1903.

784,521. Commutator for Electric Machines and Process of Making Same. Fritz A. Feldkamp, Newark, N. J. Filed April 16, 1901.

Telephones and Telephone Apparatus.

784,088. Telephone System. William D. Watkins, San Jose, Cal., assignor to the Watkins Manufacturing Company. Filed March 11, 1902.

784,292. Direct-Line Circuit and Switching Mechanism for Telephone Systems. Albert K. Andriano, San Francisco, Cal., and Hermann Herbstritt, New York City, assignors to the Direct Line General Telephone Company. Filed Nov. 21, 1903. Renewed July 11, 1904.

784,498. Automatic-Telephone-Exchange System. John K. Norstrom and Henry M Graif, Chicago, Ill., assignors to the Automatic Telephone Company, Filed May 18, 1903. Renewed July 5, 1904.

Miscellaneous.

784,024. Dynamo-Electric Massage Instrument. Albert Barrett and William Condon, Kansas City, Mo. Filed July 5, 1904.

784,034. Electroplating Device. George W. Clough, Cleveland, O, Filed Jan. 30, 1904.

784,052. Electromagnetic Device. William Kaisling, Chicago, Ill., assignor to the Kellogg Switchboard & Supply Company. Filed Oct. 17, 1901.

784,125. Galvanic-Battery Cell. Albert T. Sanden, New York City. Filed Dec. 15, 1904.

784,186. Thermostat. John E. Shepherd, Chicago, Ill, Filed April 25, 1904.

784,226. Electrical Fuse-Primer. Francis M. Quinn, Silverking, Idaho. Filed Sept. 17, 1903.

784,328. System of Electrical Distribution. Frank Hoffman, Chicago, Ill., assignor of one-half to Elmer E. Hanna, same place. Filed May 21, 1903.

784,454. Electric Heater for Oil or Gas Wells. Fred B. Waring, Lima, O., assignor of one-half to Ira R. Longsworth, same place. Filed April 22, 1904.

784,457. Electrical Attachment for Musical Instruments. Josef Weber, Brooklyn, N. Y. Filed Aug. 19, 1904.

784,464. Means for Protecting Electric Cables Against Excess Pressure. Georg Zapf, Cologne-Nippes, Germany. Filed March 24, 1904.

784,502. Magnetic Ore-Separator. Lewis G. Rowand, Camden, N. J., assignor to the Wetherill Separating Company. Filed Feb. 28, 1898.

784,508. Electrically-Actuated Piano. Joseph Weber, Brooklyn, N. Y. Filed Aug. 19, 1904.

784,523. System of Electrical Distribution. Frank Hoffman, Chicago, Ill., assignor of one-half to Elmer E. Hanna, same place. Original application filed May 21, 1903. Divided and the application filed Aug. 13, 1903.

THE TELEPHONE WORLD.

Syracuse Independent Association Organized.

The Syracuse district of the New York State Independent Telephone Association was organized this month with the following officers: Chairman, F. M. Potter, Jr., Syracuse; vice-chairman, F. S. Stockwell, Oswego, and secretary, H. W. Fluhrer, of Auburn. Twenty-five telephone men were present and considerable enthusiasm in the work was shown. The next meeting will be held at Auburn, May 4.

The purpose of the organization was to bring about a closer relationship among the operating systems. The State is divided into 12 districts. Each district will elect a representative to the New York State Independent Telephone Association, and in turn this association will elect delegates to the National Independent Telephone Association.

The Independent companies are strong in the small towns and in the country districts.

Farmers in all parts of the State are considering the advisability of organizing small companies of their own on the co-operative system. The farmers of the town of Van Buren are said to be talking of the advisability of such a plan. In the town of Lysander also there are no telephone connections in the country, and it is believed that a farmers' company could be formed there without serious difficulty.

The Home Telephone Company, of Kansas City, has paid into the city treasury $1,779.01, which represents 2 per cent. of the gross receipts of the company for the three months ending December 31, 1904. During the 10 months the company has been in operation its total gross receipts have been $236,038.84 and the city's share of this sum has been $4,702.77.

It was lately decided at a business men's meeting in Cadillac, Mich., to use the service of the Citizens' Telephone Company, and discard the Bell. The service at Cadillac is being much improved, and a new toll line from there to Harrietta has just been completed. The Citizens' Company now has 755 telephones at Cadillac, and 75 more orders which are being filled, whereas the number of telephones three years ago, when the Citizens' Company entered the field, was but 209, showing the remarkable growth which has been made by the company there.

The Syracuse, N. Y., Telephone Company is still considering extensive improvements for that city, and it is said that the work will be taken up as soon as it can be financed. A large sum of money will be spent, the company claims, and the service greatly improved.

The annual convention of the Ohio Independent Telephone Association will be held in Columbus on March 30.

The sum of $16,244.49 has been paid in dividends by the Valley Telephone Company, of Saginaw, Mich., during the past year.

The Peninsular Telephone Company, of Detroit, Mich., is planning to spend $25,000 in underground construction work.

A 6 per cent. dividend has been declared by the Chippewa County, O., Telephone Company.

New Independent Line to St. Paul.

The West Wisconsin Telephone Company, with headquarters in Glenwood, has arranged to build a line from there through the town of Erie to connect with the Hammond Independent lines, giving connection with all the Independent lines of St. Croix and Pierce Counties. This plan will give a second long distance connection between Glenwood and St. Paul, Minneapolis and all points north as far as Duluth. Work on construction is expected to begin May 1.

The directors of the Heath, Mass., Telephone Company, at a recent meeting, voted to pay a 6 per cent. annual dividend in April—probably by the 10th. On the 15th the stockholders meet to act on a proposed increase of the capital stock, which is now $30,000. The directors favor an increase of $20,000, bringing it up to $50,000. There is an increased business in sight that will keep the company busy with extensions. There is a surplus of $3,700 in the treasury and all the bills paid.

A largely attended meeting of Tuckahoe Neck farmers and business men from Hillsboro and Denton, gathered in the town hall of Ridgely, Caroline County, Md., a short time ago, to discuss the rural telephone system. The company was capitalized at $2,500; 74 shares at 30 a share have been subscribed for the telephone system, which will be known as the Farmers & Merchants' Telephone Company, and it is now an assured fact, and will run from Hillsboro, Denton and Ridgely and the farming community surrounding the towns. George S. Raleigh was elected president of the company.

Over the trunk lines of the United Telephone & Telegraph Company, running between Pottsville, Danville, Shamokin and other points in Pennsylvania, there speed each day between 9 and 3 o'clock both telegraph and telephone messages over the same wires and at the same time. This plan is now proving serviceable in a rush of business.

The annual banquet of the Frankfort Hill Telephone Company was held recently at the home of the President, George Sass, in Frankfort, N. Y. The company is in excellent financial condition, new and important improvements being made and the line is now one of the best local institutions of the kind in the county.

The Keystone Telephone Company's net earnings are reported to be exceeding $30,000 a month. It is said that the friends of the company will take over the $2,400,000 of floating debt.

A. M. Fogg, of East Hebron, Me., will begin in April to establish a local line of telephones in Hancock County, which will extend from Aurora to Ellsworth.

A dividend of 8 per cent. was recently declared by the Beaver Township Telephone Company, of North Lima, O.

A clean profit of $10,000 was made last year by the Valley Telephone Company, of Lebanon, O.

Kinloch Company Will Have a New Exchange.

The Kinloch Telephone Company, of St. Louis, Mo., is preparing to erect a large fire-proof building on the corner of 10th and Locust streets. The new exchange will contain one of the largest switchboards in the world, and all the instruments to be connected will be up-to-date. The style adopted for the design of the building is modern Renaissance. The interior will be constructed with steel columns and floor beams incased and filled in between with re-inforced concrete. The first and second stories and a portion of the basement are to be used for wholesale purposes, and the remaining portion of the basement, together with the third, fourth, fifth and sixth stories, by the telephone company, the operating room occupying the entire sixth floor. No pains or expense will be spared to make a thorough, complete and convenient exchange. Special attention has been given to the heating and ventilation. The entire building will be ready for occupancy the latter part of the year, plans having been completed and the contract let.

The Kinloch Company is a home institution, owned, controlled and operated entirely by St. Louisans. Six years ago the Kinloch Company began operation with 4,000 subscribers. It now has 15,000 telephones in service.

Recently toll connections have been completed by the Kinloch system throughout Missouri, Kansas, Illinois, Kentucky, Ohio, Pennsylvania, West Virginia and nearly all the cities and towns throughout the Central States.

In addition there is through service to such cities as Kansas City, Indianapolis, Louisville, Columbus, Cleveland, Pittsburg, Baltimore and intermediate points, reaching, it is claimed, over 350,000 Independent telephones.

The Missaukee Telephone Company of Lake City, Mich., voted at its annual meeting to declare a dividend of 6 per cent. in addition to the regular 8 per cent. already paid during the year.

The York County, Neb., Independent Telephone Company recently paid its 5 per cent. semi-annual dividend, making a total of 10 per cent. net dividend for the year.

The Citizens' Telephone Company, of Racine, Wis., will shortly offer for sale bonds to the amount of $200,000.

The Citizens' Telephone Company, of Delaware, O., has increased its capital stock from $100,000 to $125,000.

The Citizen's Telephone Company of Montevideo, Minn., has declared a semi-annual dividend of 3 per cent.

Telephone Incorporations.

The New Knoxville Telephone Company, of Auglaize County, Ohio. Capital stock, $8,750. Incorporators: A. H. Steinecker, George W. Hall, F. H. Fledderjohann, George Wellman, E. H. Medstroth and others.

The Greentown Telephone Company, Greentown, Ind. Capital stock, $30,000. Directors: J. M. Glenn, W. L. Bott and Art A. Sargeant.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Alachua, Fla.—An ice plant, electric light and water plant will be built here by T. B. Springfellow, of Jacksonville, and Robert Legueston, of Gainesville.

Bailey, Col.—W. E. Hurd, C. E., is planning to build an electric plant to furnish electric lights for all the resorts from Shawnee to Pine and Buffalo.

Ballard, Wash.—Fred S. Simpson, manager of the Ballard Electric Company, will petition the city council for an electric light franchise.

Bay City, Mich.—The council has granted a franchise to West Bay City for commercial electric lighting here.

Benton, Tenn.—It is announced that L. A. Wyatt will install an electric light and power plant, and has secured the contract for furnishing the city with lights.

Brownsville, Tenn.—This city contemplates installing an electric light and waterworks plant.

Clayville, N. Y.—The Clayville Paper Company will install a plant for furnishing electric lights to this village. The principal office of the company is at Syracuse.

Concord, N. C.—It is reported that this city contemplates issuing $13,000 of bonds for improving the electric light plant. Address Quint E. Smith, city engineer.

Dickinson, N. D.—The electric plant of this city is being enlarged.

Foley, Minn.—Daniel Stimler, of Minneapolis, has applied to this village council for a 20-year franchise for an electric light plant.

Freeport, N. Y.—The Freeport Gas & Electric Company has been incorporated. The capital stock is $1,000, and the directors are Lee W. Wertheimer, of New York City; H. C. Miller, of Tarrytown; Louis A. Klipp, of Brooklyn

Ft. Valley, Ga.—An election to issue bonds to the amount of $12,000 for the erection of an electric light plant here has been carried.

Greenville, Ala.—The C. C. Henderson Electric Light Company has secured a franchise for the establishment of an electric light plant.

Gretna, La.—It is reported that the Algiers, La., Waterworks & Electric Light Company will extend its system so as to furnish this place with electric lights.

Henderson, Tenn.—The Henderson electric light plant has been purchased by Mr. Gullett, of Bells, and will be started soon.

Highland, Wis.—A special election is to be called to vote on bonding the village to raise funds to build an electric lighting plant for this village.

Howell, Mich.—A new 60 hp. engine is to be installed at the waterworks and electric light plant.

Jefferson City, Tenn.—The Jefferson City Electric Light Company will erect a new electric light plant.

Marietta, I. T.—This town has granted to J. B. Hutchins a franchise to erect an electric light plant.

McKinney, Tex.—A Dallas broker has purchased $8,000 worth of this city's electric light bonds.

Mexico, Mo.—The Mexico Electric Light Company has been granted a 20-year franchise.

Niagara Falls, N. Y.—The city council has granted a franchise to the Niagara Falls Hydraulic Power & Manufacturing Company to build conduits for the distribution of electricity for light, heat and power purposes.

Noblesville, Ind.—A 10-year contract for lighting this city has been let to B. W. Hultzmann & Co. The new company is a consolidation of the old electric light company and the Noblesville Hydraulic Company. About $150,000 will be expended in improvements, which include the construction of a new plant.

Prairie Grove, Ark.—C. L. Cummings has proposed to install an electric light plant here.

Rome, Ga.—It is reported that this city will petition the Legislature for authority to construct an electric light plant.

Shelbyville, Tenn.—This city contemplates installing an electric light plant. Address H. L. Wooley.

St. Augustine, Fla.—It is reported that Dr. Littleton, representing others, has applied for a franchise to install an electric lighting plant.

Terre Haute, Ind.—The McCulloch Company of St, Louis, Mo., has been engaged to prepare plans and estimates for the erection of a municipal electric light plant here.

Tulsa, I. T.—The People's Gas Company has been granted a franchise to wire the city for electricity.

Valdosta, Ga.—This city contemplates installing an electric light plant with a capacity of 60 to 100 arc lights. D. G. Griffin, or W. D. Peoples, chairmen of the electric light committee, may be addressed.

Valley Junction, Ia.—The Valley Junction electric light and water plant, has been sold to a private company, composed mostly of local parties.

Waynesfield, O.—W. H. Bailey contemplates establishing an electric light plant here.

STREET RAILWAYS.

Albany, N. Y.—The Interborough Rapid Transit Company of New York has obtained a decision from the Court of Appeals requiring the State Board of Railroad Commissioners to issue to it a certificate authorizing it to construct six new lines in Bronx Borough.

Austin, Tex.—The Houston-Galveston Electric Railway Company, capitalized at $350,000, purposes to build an electric railroad between Galveston and Houston. Incorporated by Frank P. Read, William Johnson and others.

Boone, Pa.—An electric line is to be constructed from this city to Ft. Dodge.

Corry, Pa.—The Corry-Findley, Lake & North East Railway Company was lately incorporated at Albany, N. Y., to operate an electric road 13 miles long in Chautauqua County, on the border line between New York and Pennsylvania. Its capital stock is $130,000. Charles P. Northrup, of Warren, and M. Raymond, of this place, are the incorporators.

Gulfport, Miss.—It has been decided to build an electric road to connect this city with Biloxi. J. T. Jones and W. T. Jones are interested.

Lansing, Mich.—The Lansing & Suburban Traction Company proposes the construction of an electric line from this city to Jackson, if the necessary right of way and franchise can be secured.

Mountain Home, Idaho.—An electric railway is proposed for this city.

New Castle, O.—The city council has been asked by the New Castle Electric Railway Company for a 50-year frenchise.

Pottsville, Pa.—The Tamaqua & Pottsville Electric Railroad Company has been granted a franchise for building two branches through the town of St. Clair.

Watertown, N. Y.—Loomis Allen, of the Utica & Mohawk, has made an inspection of the Rome road from Carthage to Sacketts' Harbor, with a view to equipping that road with electricity between the places named. It is more than probable that the 30-mile stretch will be equipped before the end of summer.

POWER PLANTS.

Blacksburg, Va.—It is reported that plans will be prepared by L. S. Randolph, C. E., of this city, for the proposed power plant to be built at the Western State Hospital, to consist of a duplicate generating plant, and a power and distribution system of motors.

Chicago, Ill.—Sears, Roebuck & Co., of this city, will erect a new power plant at Pullman. The plant will be of 12,000 hp, and will be capable of running 30,000 electric lights.

Spokane, Wash.—The Spokane Traction Company will soon erect a $700,000 power plant at Coeur d' Alene, Idaho. Jap P. Graves is president of the company.

Turtle Creek, Pa.—The Rose Hill Electric Light Company, of this place, has purchased a site for the construction of a new power plant.

Wichita, Kan.—The Citizens' Light, Heat & Power Company, of this city, will soon commence the erection of a new power plant. H. G. Landis is interested.

BIDS WANTED.

Camden, N. J.—Sealed proposals will be received at the city clerk's office until March 20 for lighting the city hall with electric lights. A certified check for $25 is required. C. H. Turner, chairman property committee, city hall.

Chicago, Ill.—Bids will be received until April 12, by S. D. Griffin, clerk of the sanitary district of Chicago, for building the power house of the Lockport Power Development Company, near Lockport.

Little Rock, Ark.—Sealed bids will be received by L. W. Cherry, until March 20, for the installing of steam boilers, engine, pump, etc., in the new Little Rock High School, in accordance with plans prepared by Architect Frank W. Gibb, 2-4 Reider Building, this city, A certified check for $200 is required. L. W. Cherry, chairman building committee.

Mannington, Ky.—The Mannington Coal & Coke Company wants prices on electrical equipment. J. B. Williams, president, Frostburg, Md.

Selma, Ala.—Peacock's Iron Works of this place is in the market for a 50-light dynamo.

Thomasville, Ga.—The Thomasville Chair Company wants prices on engines and boilers.

Wilmington, N. C.—The Southern Electric Company, Old Courthouse Building in this city, is in the market for a marine generating set, consisting of six kilowatt 110 to 125 volt generator, direct-connected to a 10 hp. vertical engine.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 15⅛@15¼c.; Lake 15¼@15⅜c.; casting, 14⅞@15c.

The United Traction & Electric Company of New Jersey has declared a dividend of 1¼ per cent., payable April 1.

The Delaware Interurban Railway Company, capital $500,000, has been incorporated to build an electric road in and about Wilmington.

A Philadelphia dispatch says that two parties, well known in financial circles, are seeking to obtain control of Electric Company of America.

The value of the $105,000,000 outstanding traction stocks and bonds issued by Chicago companies is dependent on the result of the municipal election in that city.

The Metropolitan Street Railway Company of New York will pay the regular guaranteed rental of 1¾ per cent. on April 16. Books close March 24 and reopen April 16.

The regular quarterly dividend of 1¾ per cent. on the stock of the Manhattan Railway Company of New York will be paid on April 1. Books close March 17 and reopen March 30.

A special meeting will be held March 16 to increase the capitalization of the North American Company to $30,000,000. The North American Company now has practical control of the lighting and street railway interests of St. Louis.

A big financial transaction has just been completed in Montreal, Canada, whereby certain large holders of stock in the Montreal Light, Heat & Power Company transfer to London capitalists 20,000 shares in that company at the par value of $2,000,000.

The shares of the Interborough Rapid Transit Company of New York on Saturday rose 6½ points to 220½. This is an advance from 203¼, the low price touched on Tuesday of last week, the first day of the Subway-elevated strike. The high record for the stock is 226.

The Philadelphia Rapid Transit Company contemplates beginning a ten-mile subway in Broad street, Philadelphia, about the time the Market street subway and elevated line westward from the Delaware River is finished. The cost is estimated at $1,000,000 a mile.

A cable dispatch from Paris says that Frank Tilford, of the firm of Park & Tilford of New York, has purchased a controlling interest in the Paris Electric Lighting plant for $3,000,000. A later dispatch, however, says the managers of three of the big Paris electrical companies claim there is no truth in the report.

The offer of the New York, New Haven & Hartford Railroad Company to purchase the Hartford Street Railway has been accepted, the compromise figure being $285 cash a share for this stock, and $285 for the East Hartford & Glastonbury Horse Railway Company's debenture bonds. The offer was made to all holders of stock and debentures, and has been accepted by a majority of both.

The report of the Western Union Telegraph Company for the March 31 quarter is very much better than might have been expected, in view of the severe storms which the company was obliged to encounter early in the quarter. The estimated figures just issued for the quarter show a decrease of $137,000 in comparison with the actual figures for the same quarter of last year. As the company is always conservative in its estimates, it is certain that the actual figures will reflect a loss, probably, of not more than $100,000.

EDITORIAL NOTES.

The Resources of Alaska

The recent discussion about the present and future status of Alaska as regards its relationship to the United States has been the means of drawing attention to the present and future prospects of that vast region, its limitations and its resources. The most urgent need of Alaska at the present time is adequate railroad facilities. Given these, and there will soon be a rapid development of trade, highly reciprocal in its nature.

While Alaska is a territorial possession of the United States, it has not yet been accorded a territorial form of government. It has now about 26 large cities and towns, not to mention the scattered mining camps throughout the length and breadth of the land. Its natural resources are such that there must be a constantly increasing population, much of it of a permanent character. The area of that country is 329,529,000 acres, of which 272,000,000 acres are in the temperate zone. Thousands of miles of its coast line are warmed by the Japanese currents; all known minerals are found there, some in great quantities.

This being indisputable, it might be interesting to go a little further into its resources, development and commercial possibilities.

The Alaskan telegraph was opened for business over the entire system on August 23, 1903, since which time it has been operated with a reasonable amount of success up to the present time.

During the past fiscal year the line was interrupted 206 times due to snowstorms, blizzards, sleet and ice, high winds, forest fires, etc. The longest interruption occurred during the month of August, 1903, between Tolavena and Chena, covering a period of 18 days, and was due to forest fires.

The lines from Fort Egbert to Valdez, and from Fort Gibbon to Fort St. Michael are in good condition, while the Tanana section is only in fair condition.

The cable offices at Juneau and Skagway were in operation before July 1, 1903, and the cable to Haines Mission was completed and that office opened on July 21, 1903. The cable to Sitka was completed October 2, 1903, and the office opened the same date.

The impossibility of maintaining a cable across Norton Sound, between Fort St. Michael and Safety Harbor, due to a destructive action of the ice in the spring, led to an attempt to communication by wireless telegraph, and this was put into effective operation about August 1, 1904.

Cable communication has also been established between Sitka and Seattle, and work is now being carried on between Valdez and Sitka.

A great degree of satisfaction is expressed by those in authority over the work of the Signal Corps in extending telegraphic communication with Puget Sound. When the part between Sitka and Valdez shall have been completed we shall have an all-American route for communication and feel in a great measure independent. The immense value of this to the Government in governing the territory can hardly be overestimated, and it is felt that Congress has been fully justified in going to the necessary expense entailed by its construction.

Another element of importance in connection with our Alaskan possession, is its immense possibilities of supplying our demands for copper. The mine at Ellamar, Prince William Sound, has produced 20,000 tons of ore, which were shipped to the smelter at Tacoma, Wash. Shipments of this ore from La Touche Island in the same sound have begun. A number of other properties in this locality are under process of development. Among these may be mentioned the Boulder Day group of the Reynolds-Alaska Development Company. Development work was carried on upon the great ore bodies along the Chityna and its branches, especially upon the Elliott, Hubbard and the Bonanza group. These mines cannot be profitably utilized until there is a railroad built to them. The copper ore deposits upon Prince of Wales Island have recently been undergoing development. Ore from one claim is being shipped to a smelter in British Columbia. A smelter of large capacity is under construction at Hadley, and another at Copper Mountain. There can be no doubt as to what Alaska will do in the near future in the way of copper production. Cheap water transportation favors the mines along the coast, and the riches of the ore there and in the interior, favors its being worked at a profit.

The returns for the past fiscal year show that the shipments of equipment for electric railways from the United States to Alaska reached a value of $1,661; 7,473 pounds of copper in bars, ingots, etc., at a value of $2,134; and of all other manufactures of copper to a value of $3,934; while of electrical appliances, including telegraph and telephone instruments, the total value of the shipments reached the sum of $50,702. That of electrical machinery is reported as being $22,351. Our receipts of copper ore during the year, amounted to 5,745 tons at a value of $137,703; while of manufactured copper the value was $4,897. Recent surveys that have been made show that there is practically an unlimited field of copper in Alaska to be developed.

* * *

Why the Coal Consumption is so Heavy.

Statisticians provide estimates which sometimes defy criticism. They indicate with almost barometric precision the drift of industrial development and clearly show the tendencies of the times with regard to the greater causes of human effort. That which we call the products of manufacture are classified and rated with the result that we know how much machinery is being made. We are made familiar with the extent to which all articles of general use are produced and are thus able to know where the wheels are turning fastest and longest. The records of the nations' demand for foodstuffs are kept as shown by the statistical sales of cereals, and the degree of consumption in other directions, covering a vast list of utilities and domestic articles, supplies as it were the true scheme of national progress. This at least is the outward appearance of things; the reasons for increased consumption here or there are at times lost to sight. But behind all this activity, perhaps lying at the very foundation of it, is quite another reason. The statistician has silently pointed it out and it speaks with dramatic force to those whose education, sensibilities and training are responsive to it. It is the record of our coal consumption, which has risen from 33 million tons in 1870 to the enormous figures of 319 million tons in 1903. It might be said by some that we export a great deal of this fuel, but this is not so; the exportation does not exceed 3 per cent of the total. In other words, we burn nearly 40 per cent. of the coal of the entire world. The people of Great Britain, Germany, France, Austria and Hungary, including ourselves, last year mined and practically consumed 864 millions of tons.

What relation 319 millions bears to 864 millions it is easy to perceive. If we are burning so much coal, what is it being used for? In what department of the arts and industries or domestic life do we find a necessity arise for so great a consumption? It is evident that in general the greatest coal consumption is required for the home and hearth of a myriad of American domiciles; then come the steel and iron foundries, the busy factories, the great steam roads and finally the electric light and power plants. In this last respect the United States knows no second place. What part of the 40 per cent. of the 864 million tons can be regarded as productive of electricity for light, power and traction? It has been estimated that one billion dollars represent the earnings from electrical enterprises of all characters in the United States. If this is so, then as a large part of these earnings are derived from street railways and electric light and power plants, it can be safely concluded that at least 10 per cent. of the world's coal consumption is through these causes. The increasing use of electricity for purposes whose name is legion, means the increasing use of coal. Electricity, then, threatens to become the form of power whose increasing consumption of coal will affect the statistician's record. If the question were asked to-day "Why is the coal consumption so heavy?" some doubt would be expressed as to the correct answer. When a decade has passed, however, and the great changes have occurred which mean the use of electricity as a national commodity, a more definite answer can be given to this question and it will be framed in those letters which spell the word electricity.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

At the International Railway Congress, to be held at Washington, D. C., from May 3 to 13, several interesting papers on electrical subjects will be read.

◆

Marconi says that he has perfected a receiver which will permit the transmission of 100 words a minute.

◆

Prof. F. A. C. Perrine has gone to Mexico on an important hydro-electric project.

◆

We are informed that a hurried canvass of the different cities which will be represented at the coming convention of the National Electric Light Association shows that the attendance will be greater than had been expected. Several special trains from Eastern cities have been engaged by delegates, and a number of large parties are being organized to make the trip.

◆

The Armours of Chicago are becoming the greatest owners of municipal utility plants in the West. They control the railroad and lighting business in Kansas City, the City Railway of St. Joseph and are reputed to be the largest owners in the Omaha-Council Bluffs City Railway. The deal they are now reported working on in Des Moines is said to represent nearly $12,000,000.

◆

Prof. L. C. Herdt, assistant professor of electrical engineering at McGill University, Montreal, has been awarded the honorary title of officer d'academie, by the French Government, for services rendered in the field of art, science and literature.

◆

The Roman Tramways Omnibus Company of Rome, Italy, is shortly to adopt electricity on its roads. The first section to be constructed will be the line between the Piazza del Popolo and Ponte Milvio. The Leghorn Tramways Company will also construct a system of electric railways in Leghorn.

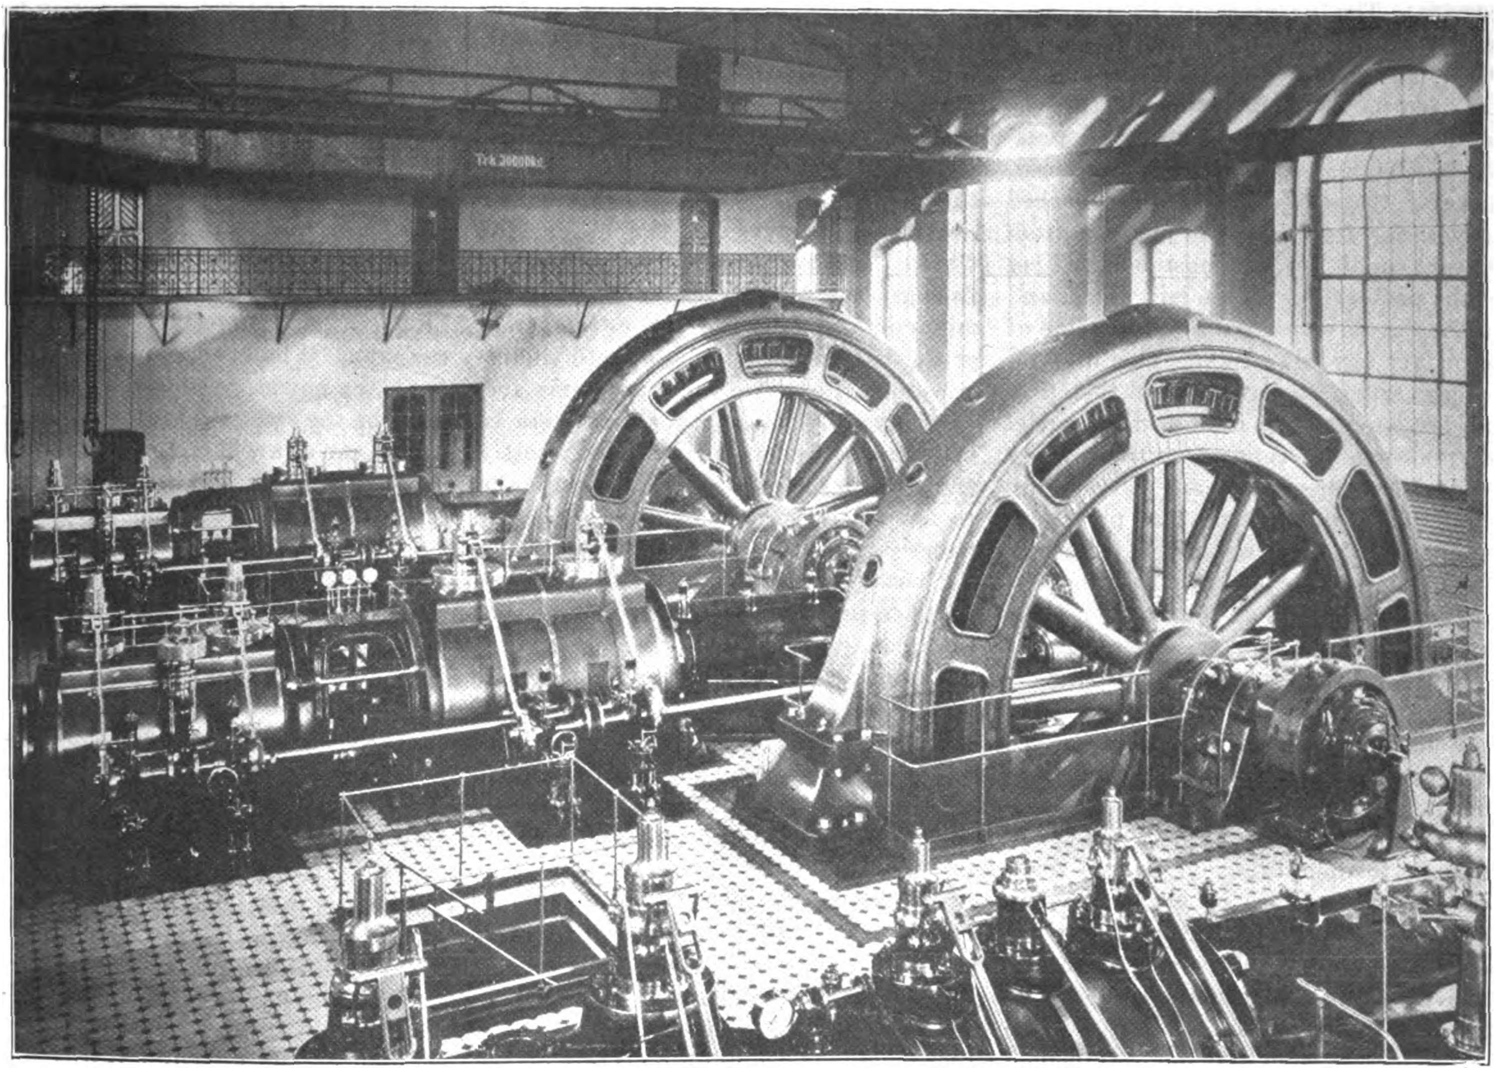
◆

The University of South Dakota, located at Vermilion, is anxious to secure the services of an assistant professor of engineering; salary $1,200 for the first year.

DRESDEN ELECTRIC LIGHT AND POWER PLANTS.

BY FRANK C. PERKINS.

The city of Dresden, Germany, has a population of nearly half a million, and is well provided with electric stations supplying current for railway, lighting and general power purposes. The Dresden Electricity Works, shown in the illustration, contains two alternators of 1,000 kilowatts, each direct connected to horizontal tandem compound engines, operating at 85 revolutions per minute, and two revolving field alternating current generators, each having a capacity of 850 kilowatts, and directly coupled in the same manner to the same type of engines at the same speed. These alternators are of the Lahmeyer type constructed at Frankfort-on-the-Main, Germany, by the Elektricitats-Actien-Gesellschaft, W. Lahmeyer & Co. The station is served by an electrically-operated crane of 30,000 kg. capacity, as noted in the background of the illustration. The normal capacity of this station at the present time is 5,080 kilowatts, and it supplies current for 92,952 incandescent lamps of 50 watts and 1,572 ten ampere arc lamps. The primary current is 2,000 volts, the secondary distribution being made at 72 and 110 volts. The motor service includes a large number of small motors having a total capacity of 1,169 hp. The station is connected with 2,390 meters, this being the usual method of charging for the electric service.



Dresden Central Station.

A combined lighting and heating plant was installed at Dresden, supplying heat and light to the King's palace and various public buildings in the vicinity. This power house was electrically equipped by the Allgemeine Elektricitats Gesellschaft of Berlin, with the exception of two steam engines and generators, the storage battery installation and the main switchboard in the power house, which was supplied by the Elektricitats Werken, formerly O. L. Kummer & Co., of Dresden. The boilers and steam piping of the combined lighting and heating power house were installed by Messrs. Rietschal and Henneberg of Dresden. There are ten boilers, including the reserve, each having a heating capacity of 2,151 square feet. These boilers also supply steam to the three direct current steam dynamos. The electrical generators each have a maximum capacity of 360 kw., the pressure being 220 volts at the terminals, and a balancer has been provided, as the three-wire system of distribution was adopted. The storage battery consists of two sets, each having two groups of 132 cells, coupled in parallel, the capacity of each part being 1,080 ampere hours. The battery has a normal charging and discharging rate of 360 amperes with the above capacity.

There are four electric railways in Dresden, including the Kgl. Sachs. Statsbahn, having a total length of track of 14.25 kilometers; the Dresdner Vorotsbahn, with a total length of track of 3.6 kilometers; the Dresdener Strassenbahn, with 61.96 kilometers of track, and the Deutsche Strassebahn Gesellschaft, with 58.85 kilometers of track. These electric railways are supplied with current from the city electric power plant, also from the Elektricitats Werk Deuben, and from a power house at the Bahncentrale Tolkewitz, the total current utilized from these various plants being from 1,500 to 2,000 kw. The cars are equipped with motors of from 16 to 25 hp. each; several hundred cars are used, about half of which are trailers, together with about 40 storage battery cars.

For a city of its size Dresden is as well provided with electric railway, light and power service as any of the larger cities in Germany.

◆

ELECTRICITY LEAFLETS.

BY NEWTON HARRISON, E. E.

Electric Railways.

Application of the Motor to Railway Service.—The inventors of electric railway appliances may be counted in multitudes, and their work in the aggregate has been the means of developing the possibilities of electric roads to their present high state. It must not be believed, however, that perfection has been reached as yet; far from it. Yet judging from present conditions, the most definite lines of the problem have been laid down, and further work will be mainly in the line of secondary improvements. The first recorded American inventor in this field was Davenport, who built a small model of an electric car running on tracks, very crude, yet operative, and thoroughly crystallizing the fundamental principles of electric railroading. It is perfectly reasonable to believe that among the first natural applications of the electric motor that would be made by experimenters would be that of applying it to some purposes of traction. As Jacobi applied an electric motor run by batteries to the running of a small boat on the river Neva and the same idea was followed by Trouve in France on the Seine, so it was found possible to operate tricycles and small four-wheeled vehicles by electricity, and naturally a small electric car. The effort has always been made to apply sources of motive power, particularly when they are new, to all known forms of propulsion. The step is an easy one—to include an embryonic vehicle to run on tracks or off—and thus to show the point of divergence of the two great inventions of this era: the automobile and the electric car. It is easy to realize that any experiments carried on in the initial stages of electric traction were destined to expand because of the new social conditions through which the density of population, by its rapid increase in large cities, called for some efficient and safe as well as rapid means of locomotion. The laboratory experiments and scientific tests soon became matters of public interest, and the question of whether the application of an electric motor to a railway truck would prove a success was soon answered in the affirmative. Such efforts as these, in this field of original work, beginning with the toy model of Davenport, have reached a point to-day represented by giant electric locomotives developing twice the power and pull of those employed on the heaviest grades of any steam road in the United States. Attention must now be turned to some of the important principles involved in a study of railroad work.

Some Mechanical and Electrical Principles Involved.—It is, of course, well known that a certain heavy mass mounted on wheels must be drawn along a pair of rails, the mass being a car, and the rails the tracks which act as guides for the car. Simple as the proposition seems at first glance, an immense amount of labor was involved in the original development of this idea.

The manufacture of the rails, the wheels, the car trucks, the system of springs, the air brakes and a host of minor details called for the development of special and ultimately gigantic industries to grapple with these problems successfully. Certain proportions were to be learned only by experiences of a costly and arduous nature and it is in a sense the review of these relationships and their underlying principles which constitute the basis of electric railroading. The simple mechanical problem of estimating the amount of power required to move a given mass a given number of feet in a given time is fundamentally the beginning of this study. Take a car weighing one ton and move it at the rate of 10 miles an hour. The question to be asked is this "What power is required to produce this velocity under ideal conditions?" A weight of one ton or 2,000 pounds moving at the rate of 10 miles an hour, or 52,800 feet, would be equal to a weight of 2,000 pounds moving at a speed of 880 feet a minute. One horse-power = 33,000 foot pounds per minute; therefore 880 × 2,000 = 1,760,000 foot pounds per minute or in horse power 1,760,000 ÷ 33,000 = 53⅓. The horse power obtained in this manner by calculation does not take into consideration the losses through friction, air resistance, slippage, etc., which must be added. In starting a car, the effort of overcoming its inertia is greater to instantly attain full speed than that developed at any other point in the process. It is of necessity a comparatively slow one in practice because of the inability of the driving wheels to grip the track firmly enough to move the suspended weight as rapidly as they rotate. Thus another principle is involved in connection with the amount of power required and this is the amount of friction between the wheels and the track. The greater this adhesion or friction, as far as the initial effort is concerned, the more rapidly acceleration will develop. The weight of the car will increase this, in conjunction with the width of the wheels and rails. The greater the number of points of contact between the car truck and the tracks the greater the effect in starting of the tractive effort. The relationship of these items is an interesting phase of general railroading and is therefore of the utmost importance in electric roads where the motive power is found under each car, practically directly over these very points of contact with the rails.

The motor employed to produce the driving force must develop sufficient pull to give the speed required. The motor may be high speed and geared by means of a pinion to the car wheels through the medium of the axle; or it may be slower in speed and directly connected to the car axle. Whatever course may be pursued, the power developed by the motor must be the equivalent of that required by the car as a whole, to reach its anticipated speed. In the last case cited the car weighed but 2,000 pounds; if its weight is greater, 5 tons for instance, the power required would be over 260 hp.

On the other hand, if the speed is increased to double, or 20 miles an hour, more than 520 hp. is necessary because of the increase in air resistance. It is evident, however, that if the air resistance is neglected, and the power required to reach a speed of 60 miles an hour is to be estimated, calculations of this character would show the necessity for developing 6 × 53⅓ × 5 = 1,600 hp. for a 5 ton car. The mechanical power, resulting from the transformation of the electrical energy in the case of an electric car, is transformed into an effort along a horizontal plane. The electrical energy sent in to produce this effect, measured in volts and amperes or watts, is transformed within the motor into a rapidly recurring series of magnetic pushes and pulls between the armature and field. The proportioning of this effort to that demanded by the weight and speed of the car is self-evident.

If a motor of 250 hp. is employed for traction purposes and it is desirable to know its carrying power at a certain speed, the following process is necessary: Reduce the electrical horse power to foot pounds per minute, divide the speed of the car in feet per minute into the foot pounds, and the value of the weight that is obtained is equal to that of *the car and the motor*. For instance, if the speed is to be 10 miles an hour with a motor weighing one ton, and the weight of the car and its appurtenances is to be known, reducing 250 hp. to foot pounds gives 250 × 33,000 = 8,250,000 foot pounds; 10 miles an hour = 880 feet a minute as the rate of speed at which entire weight can be moved. Dividing 8,250,000 by 880 gives 8,250,000 ÷ 880 = 9,375 pounds, or nearly 5 tons. If the motor weighs one ton, as stated, then the car and its appliances or load is limited on this theoretical basis to the difference between 9,375 and 2,000 pounds or 7,375 pounds. If the car carries 20 passengers of an average weight of 150 pounds apiece, included in this total of 9,375 pounds, then the subtraction made of 3,000 pounds for passengers and 2,000 pounds for the motor leaves a balance of only 4,375 pounds for the car body and trucks. The same general reasoning would apply to vehicles that do not run on trucks, such as automobiles, and in such cases a better response is obtained between the wheels and the ground than between the wheels of a car and the rails. The necessity for using heavy broad rails with corresponding wheel rims is obvious. To utilize the power of a motor economically, the wheels must not slip on the rails, particularly when starting. In street railway service these conditions are unusually severe because of the frequency of the stops and starts involved in the nature of such local service. The wear on the rails and wheels is relatively enormous, and the only means of satisfactorily withstanding the strain is to install an exceedingly solid roadbed, good steel rails and car wheels of the finest quality.

Watts and Foot Pounds.—The watts to be consumed by the motor are either estimated from the value of the load to be pulled and its rate of movement per minute, or from the motor direct, the weight and speed to be estimated from it. A 250 hp. motor equipment is not necessarily one motor; it is generally two and may be more, depending upon the length of the car body and the nature of the service. The pressure of a railway system is about 500 volts, thus reducing the current to a comparatively low value. The watts of a 250 hp. motor = 250 × 746 = 186,500, which at a pressure of 500 volts = 186,500 ÷ 500 = 373 amperes at full load. Although foot pounds are calculated in connection with horse power by the minute interval, and watts in a similar manner by the second interval, still the general rating of speed in miles per hour or feet per minute and of weight in pounds per car adjusts these differences. A 250 horse motor is producing power per second which entitles it to the rating it possesses. The power it produces per minute is only 250 hp.; the watts consumed are based upon the consumption per second, but the foot pounds ultimately given out per minute are no different from those given out by a steam or gas engine of the same rated horse power. Therefore foot pounds and watts can be transposed into each other by remembering that 33,000 foot pounds per minute is a rate of power measurement exactly equal to that of 746 watts per second.

Systems of Electric Roads.—A number of systems of electric cars have been designed whose ultimate object was the solution of the street car problem. Some of them have been tried with every sign of success at the start and have failed, others have been failures in the beginning, but are now established successes. The systems to which general reference is made are:

First—The well known overhead trolley system.

Second—The so-called third-rail system.

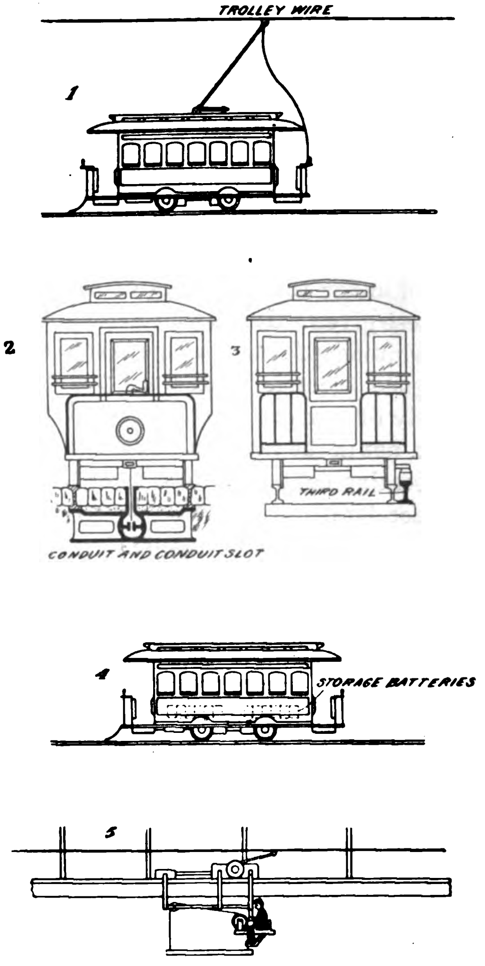
Third—The open conduit or slot system.

Fourth—The storage battery car system.

Fifth.—The automatic or electric block system.

Sixth—Telpherage and miscellaneous systems.

It is not difficult for the reader to realize that a selection of the correct system, from among this collection, suited to the special needs of cities and to suburban use, was a matter calling for the greatest sense of discrimination. It has been pretty well settled in New York that the open conduit is best suited to the peculiar requirements of the people. These requirements have been in part the result of special legislation, through which it became imperative to place all wire underground, thus excluding the overhead trolley entirely. The storage battery system was in operation for a few years under the title of the Julian system, but it did not succeed on account of the wear and tear of batteries, the difficulty of handling the same, and the possibility of breakdowns in the midst of busy thoroughfares. Other evils added their weight to the problem, with the result that a continuation of the experiment would have led to great financial sacrifices. The storage battery belongs to other fields, and experience has shown that its utility can only be profitably exhibited in them. The open conduit system was a failure for many years because of the imagined difficulty of keeping the conduit clean, and in other respects because of the inefficacy of such new improvements as were introduced to make it a success. Insulation, drainage and a system of manholes for inspection were the elementary considerations. Along with them came the correct development of a solid and effective method of construction, with the result that the system now in operation in New York City is the greatest in the world. One of the influences which led to its general adoption, was the fact that the cable system employed practically the same conduit, which with a series of secondary changes was able to perform its functions in a purely electrical sense. Thus the system of wire rope transmission for street railway service paved the way for the introduction of the electric conduit in electric car service. Sewage connections were made adequate to drain the conduit, and a substantial form of insulator was introduced to support the two rails within the conduit acting as conductors. Ducts were laid along the tracks with feeders installed, and thus the various and at one time insurmountable obstacles were overcome. The peculiarities of street car service are such that a car must start rapidly, yet without too sudden an access of speed. In fact the very expression



1—The overhead trolley system. 2—The slotted open conduit system. 3—The third rail system. 4—The storage battery car system. 5—The telpherage or monorail system.

acceleration is employed to denote this idea in actual practice. To accelerate rapidly means a great gain of time in making trips of a given length, the net result of which is the use of more cars on the track going each way. To accomplish this successfully, powerful motors are installed in the cars, and it is this possibility more than anything else that has given to electric street railways their proven superiority over other systems.

Facts to be Considered.—Street railway service, from an electrical standpoint, which might now be considered as the only one of importance, calls for a consideration of the following items:

First—Acceleration of the car.
Second—Draw-bar pull of the car.
Third—Efficiency of the car.
Fourth—Station equipment.
Fifth—Rails.
Sixth—Cost per car mile for service and power.

There are more elements than these in connection with each part of the car and station, but the greater problems are included under the headings of such titles as these given. It is a well-known fact to superintendent and managers that a well designed electric road does not consist merely of perfect machinery and equipment, but in the rating and design of cars of a seating capacity, horse power, weight and acceleration suited to the conditions of service in a given locality,

◆

PROVIDING FOR INCREASE OF POWER IN ISOLATED STATIONS.

ARTICLE I.

BY W. H. WAKEMAN.

As there are many towns and villages where a limited number of electric lights and a few small motors would be used, provided they were available at reasonable cost, and as there are many capitalists who are willing to invest their money in such enterprises, if they are sure of receiving a fair rate of interest on their investment, suggestions concerning the best power plant equipment for present use, also plans for increase of power when wanted, are of interest to all concerned.

In every place of this kind the men who are interested in conducting the business on a profitable basis look forward with pleasure to the time when more machinery will be necessary to supply the requirements due to increase of population, and the popular demand for better lighting and power service.

An important point, which is not always given the attention it deserves, is that when a plant is designed and installed provision should then be made for the enlargement which in the natural course of events is to follow.

In these articles the power plant only is to be considered, and to those who are not familiar with problems presented in connection with economical steam engineering it may seem to be a simple proposition. So far as providing enough power is concerned it is simple, but when we remember that in order to secure best results the boilers and engines composing a plant must be proportioned to the load they are to carry, and as this load is not to remain constant it makes the problem more complicated and adds interest to its study.

Due consideration of these facts show that it is not the best practice to install one or more large boilers and give them a very light load at first, because the rate of combustion will be too low. I am not in favor of a very high rate of combustion, because it rapidly destroys brick furnaces and wears out boilers. It is not economical so far as the evaporation of water is concerned. Slow rate of combustion results in small repair bills, but is not economical, therefore a medium rate is recommended if the load is not to be changed very much.

If there is load enough to work one or more boilers nearly to their rated capacity it is well to install them, taking care to provide room for more in the same battery. It is always a good idea to have at least one more boiler than is required to carry the load, so that the engineer can take all the time he deems proper to clean or repair one of them whenever necessary, rather than to cool it off quickly, do the job in a hurry under unfavorable conditions, resulting in unsatisfactory work, then fill it with cold water while it is still hot and fire it up as rapidly as possible.

The rate of combustion mentioned refers to the number of pounds of coal burned per hour on each square foot of grate surface, therefore if there is one large boiler with a grate that is large accordingly the rate may be too low. In such a case it may be raised, without burning any more coal, by covering a part of this grate with fire-brick. When the load is increased these brick can be removed, thus making it possible to run the boiler to its full capacity.

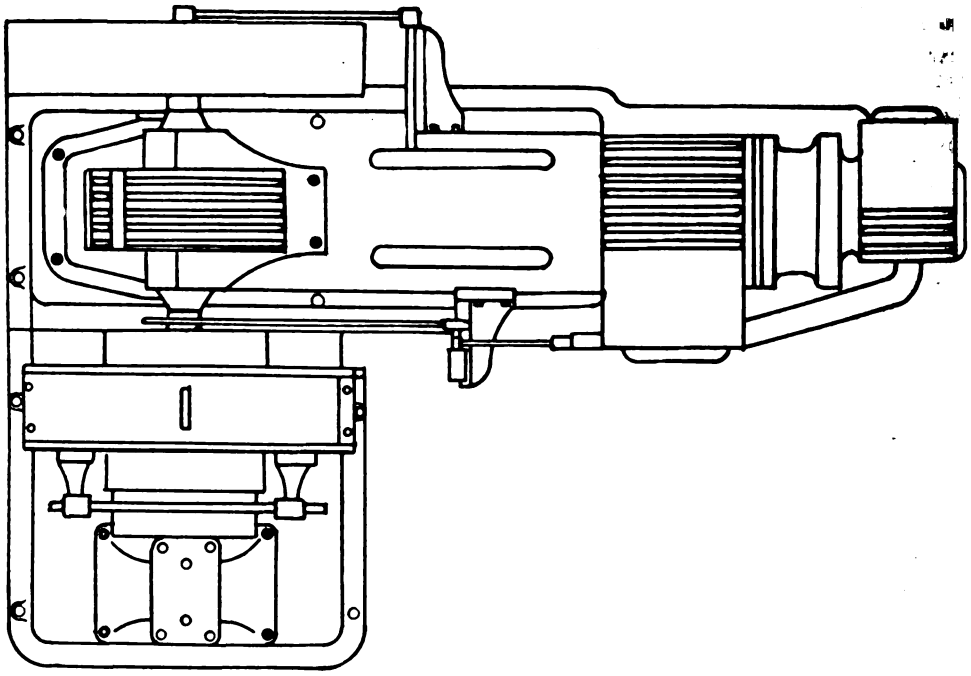


Fig. 1.

Boilers for this service should be designed and built so as to be safe when carrying at least 125 pounds pressure. While the load is light it may be a good idea to carry about 75 pounds, then when it is increased the working pressure may be raised accordingly. As boilers grow old it is necessary to reduce the limit of pressure allowed, according to the condition of plates and tubes, therefore they should be strong enough for a high pressure when new.

Coming now to the engine required, we find that there are several ways of providing for more load in the future. Fig. 1 is the plan of a short direct connected high speed engine of the tandem compound type. These engines are usually calculated for high boiler pressure in order to secure the best economy, which means that the steam cylinders are small for the required service. If a comparatively low boiler pressure (say 75 pounds) is to be used during the first year, and the first machine is to be worked to the full capacity of the generator on the crank shaft, it becomes necessary to secure a larger steam cylinder.

There is a high speed direct connected engine near my desk which is singing softly as I write. On this size the makers usually put a 10-inch steam cylinder for 120 pounds boiler pressure, but as I carry only 70 a 12-inch steam cylinder was used and it gives satisfaction.

Perhaps one of these units will be enough for the first year, and when more power is wanted another can be installed, followed by others of the same kind when wanted. The objections to this plan are that a station filled with small, high speed units requires more care and attention than where a less number of larger units are used. Furthermore these engines are not as economical in the use of steam as some other kinds.

Fig. 1 illustrates a tandem, as before mentioned, which is more economical than a simple engine when the load is just right, but otherwise it may give no better results than the less expensive simple engine. This refers more especially to non-condensing engines.

THE OSMIUM LAMP.*

The total energy radiated by a heated body is proportional to the fourth power of the absolute temperature of the body. As the temperature increases, the percentage of the short waves emitted, as compared with those of long length radiated, increases also very rapidly; but the absolute value of this percentage varies for different bodies, being smallest in so-called "black" bodies, but comparatively high in bodies with a metallic luster and smooth surface. Only these short waves, it need hardly be said, are observed as light. An efficient light-giving body must, therefore, withstand very high temperatures; its radiating surface, at a given efficiency, should be as large as possible; the substance of the filament should be transparent or white to minimize the effects of blackening; the surface of the filament should not become blacker or rough with use, and its resistance should increase with increasing temperature.

Osmium, generally in the form of osmium-iridium, is found in platinum ores and also in gold sand with gold and silver. It is at present usually obtained by alloying the residue which remains when platinum is dissolved in aqua regia, with metals, such as zinc, lead or tin. The osmium-iridium passes thereby into a finely-divided state and if it is now heated in a current of oxygen it will split up into osmium tetroxide and iridium. Osmium may then be obtained by treating the osmium tetroxide with any reducing agent.

When Herr Auer von Welsbach invented the osmium lamp some six years ago, he found it impossible to draw osmium in form of wire, and he first tried the expedient of coating platinum wire with osmium and evaporating subsequently the greater part of the platinum. It was observed, however, that a platinum-osmium alloy was formed which—when containing more than 4 per cent. of platinum—began to melt when the platinum was being evaporated. In order to keep the percentage of platinum below this figure, the finished filament had to be made about five times thicker than its platinum core. As uniform platinum wire was not obtainable in thicknesses less than 0.02 mm., it will readily be seen that the osmium filaments could not advantageously be made in diameters below 0.1 mm. Such filaments, however, are not suitable for lamps consuming less than 1 ampere.

The next and final step was to mix most finely divided osmium with certain organic binding substances to a thick tenacious paste. This paste is forced under high pressure through a diamond or sapphire die on to a card which is moved about in such a manner that the filament is deposited in loops. After drying, the organic binding substance is carbonized by heating the filament in vacuo. This porous filament, rich in carbon, is then gradually heated to an intense incandescence by an electric current in an atmosphere containing much steam and a certain quantity of reducing gases. The carbon of the raw filament changes into carbon oxide and carbon dioxide, and after a relatively short time the filament consists of pure, or very nearly pure, osmium only, the percentage of carbon being insignificant. Although the density of the filament has greatly increased during this process, the filament is still porous and its surface is far from smooth. After trying unsuccessfully several means of connecting the filament to the platinum leads, it was found that a very satisfactory method was to fuse them together by the electric arc. Osmium is brittle when cold, but soft when heated, and for this reason the lamps as made at present are required to burn in a definite position.

When the manufacture of this lamp was taken up by the Deutsche Gasgluhlicht Actiengesellschaft, the highest voltage that the lamp could stand was 27 volts. After the lamps had been perfected to burn at 37 volts, they were put on the open market. The lamp voltage was soon after brought up to 44 volts, and during the last few months a considerable number of 55 and 73-volt lamps have been sold. Quite recently 110-volt lamps have appeared.

The filament of an osmium lamp for 37 volts, 25 cp. (Hefner units), consuming 1½ watts per candle power, has a diameter of 0.087 mm. and a length of 280 mm. The radiating surface is from 3 sq. mm. to 3.2 sq. mm. per candle power. If an ordinary glow lamp be run at 1½ watts per candle power, its radiating surface per candle power is only 1.6 sq. mm. The carbon filament, therefore, must be both hotter and "blacker" than the osmium filament. With an increase of voltage of 10 per cent. the current increases 6.5 per cent. in the case of the osmium lamp, and 12 per cent. in the case of the carbon filament lamp. The corresponding increase in illuminating power is 40 per cent. and 80 per cent. respectively.

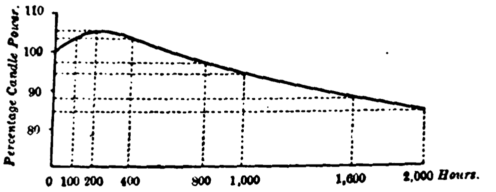

FIG. 1.
Percentage and variation in candle-power of 37-44 volt and 25-32 (Hefner) cp. Osmium Lamp.

It is not possible to state definitely the life of an osmium lamp, but 5,000 hours have been repeatedly exceeded. Figs. 1 and 2 represent the relationship of illuminating power to time—for a 37-volt lamp and 110-volt lamp, respectively. Blackening of the bulb is very rare (observed in 10 per cent. only of the lamps investigated so far).

The surface of the lamp filament is at first somewhat rough, but it gradually becomes smoother and this is the reason why the candle power increases during the first 250 hours or so. Before the lamp is ready for sale, it is burned in the factory for several hours in order to bring the lamp up to an approximately steady state.

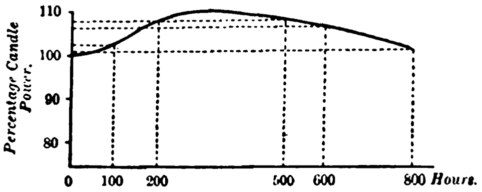

FIG. 2.
Percentage of variation in candle-power of 110 volt 32 (Hefner) cp. Osmium Lamp.

If the lamp is run at less than 1½ watts per candle power, the structural changes in the filament occur too rapidly for practical purposes. Nevertheless, lamps consuming 1 watt per candle power only, have been observed to burn for several hundreds of hours without decrease in light. When exposed to hard shocks, the osmium lamp filament is more liable to break than the carbon filament, but if properly packed the loss through breakages in transit is small, being only about 1½ per cent. These lamps stand the shocks of railway carriages and omnibuses very well. The osmium lamp is efficient also for very low voltages and a large number of 2-volt lamps for mines are in use in connection with portable accumulators. For a long time it was not possible to make thin filaments, but recently it has become feasible to reduce the diameter down to 0.03 mm.

---

*Abridged translation of a paper read by Herr Fritz Blau before the Elektrotechnischer Verein of Berlin, Jan. 24, 1905. From the "Electrician," London.

After the paper had been read, Prof. Wedding mentioned some tests which pointed to the fact that the blackening of the bulb in ordinary carbon filament lamps had no marked effect in diminishing their candle power. Amongst a large batch of ordinary 16 cp. incandescent lamps he was testing there were four which burned 14,000 hours. During this time the illuminating power fell to 5 cp. and 6 cp. The original glass bulbs, which, of course, were much blackened, were then replaced by fresh ones without damaging the filament. The illuminating power, however, had not benefited to any extent by the substitution, and Prof. Wedding concludes from this that the black deposit inside an incandescent lamp of the carbon type screens very little light.

SERIES ALTERNATING ARC LIGHTING.*

BY E. P. WARNER.

(*Concluded from page 154.*)

The durability of a lamp and the adaptability for long continuous service depend to some extent on the parts of the regulating mechanism remaining at a reasonably low temperature. In order to obtain such low temperature parts must be made of sufficient size and superficial area to readily dissipate the heat generated by losses in the mechanism and heat which may be conducted from the arc. The rise in temperature by such mechanism after a run of 12 hours should not exceed 50 degs. C. above the temperature of the surrounding air.

In the choice of inclosing globes it has been found that ordinary clear glass gives the greater general satisfaction, the distribution or diffusion of the light from the arc effected by the globe being practically as good as from any form of tinted or opalescent globe after one or two hours' operation. Practically the only reflector which can be used in combination with the alternating arc lamp is one placed above the arc and outside of the outer globe. I would say in this connection that certain users are making use of the reflector without employing an outer globe, making use of special tempered glass inner globes, which will stand the action of the elements very well. This is even accomplished in tower lighting, where the force of the wind is very great and rain and snow have full sweep. Reflectors which are very small cannot be applied practically to the alternating arc, for the reason that the upper lobe of light is so disposed that it cannot reach a reflecting surface which is very close to the central line of the lamp. This is true of the conditions in all positions of the arc in the inclosing globe. Effective reflectors can be and are applied which are so nearly flat disks that they do not offer much surface to the wind and hence do not cause the lamps to swing badly. The point has been raised that owing to the deposit of semi-opaque material up on the inner surface of the globe, the lighting efficiency is very materially reduced after a run of 40 or 50 hours and that the deposit of this material is determined to some extent by the character of the gas cap or plate which closes the upper end of the globe. We have found this to be true to a very limited extent and that the lamp which had the metal gas cap conducted away the heat from the inner globe more readily and caused the lamp to run with a lower temperature in the inner globe, and thus to deposit less of the objectionable material upon the surface of the globe.

Another result of this lower temperature was the fact that some of the material so deposited was burned into the surface of the glass, as is often the case in lamps where a high temperature is maintained. It follows, therefore, that the general lighting efficiency of a lamp with a metal gas cap is considerably higher than without.

It has come to my attention in a number of cases that the central station men engaged in making preliminary tests of arc lamps, have endeavored to compare the different lamps offered on the basis of number of hours' service with one trimming. In this they have apparently lost sight of the fact that the number of hours' service with a trimming is controlled solely by the carbons, and the amount of light given, the lamps having in fact nothing whatever to do with the result. In order to give a good steady light of sufficient power, it is necesssary to admit a certain amount of air to the inclosure, restricting this amount only to the point where high lighting efficiency and reasonable length of life are obtained. We reach a point in this line of research where one line crosses the other; there we must stop, knowing that a displacement in either direction will give unsatisfactory results.

In this connection I would say that nearly all the reputable manufacturers of arc lamps of the present day are practically unanimous as to the most desirable conditions in respect to the above features, and it is only the unprincipled dealer who tries to influence the customers by claims for greater life that can be given with satisfactory lighting power.

In conclusion I would say the results which have been achieved in series alternating arc lighting, during the past three years, are of a character to give confidence to the central station engineer, that the system has come to stay, and is one which may be safely adopted with all the probable contingencies which may arise in the near future well in view.

THE ELECTRIFICATION OF ENGLISH CANALS.

(From our London Correspondent.)

The canal system, which before the railway period served English manufacturing industries so well, is to-day to a very large extent under the thumb of the great railway companies. The canals were absorbed from 1821 onwards by their rival, the railway, for the purpose of stifling competition. During the last few years there has been a great outcry against this stifling process and the high railway rates which it has encouraged, and this outcry is becoming louder every year. The matter is very much to the fore at this moment, both as the result of attention which has been given to it by the great Chambers of Commerce, and as the result of proposals for Government confiscation of neglected or inefficient canals. The question of electrification quite naturally fits in with the proposals to revivify them. In the course of a valuable contribution read by Mr. B. H. Thwaite, before the London Society of Engineers on March 6, the author gave some interesting facts relating to recent work, and an estimate of the cost of nationalizing and electrifying the entire

---

* Paper read at the 13th annual convention of the Northwestern Electrical Association, held at Milwaukee, Wis., Jan. 18-20, 1905.

English system. He said that the narrow width of the average towpaths and their constructional character, makes any system that relies on the tractive effect of a locomotive running on the towpaths more or less impracticable; and it is obviously irrational to suggest a method of haulage that requires considerable energy on overcoming the haulage instrument *per se*. These two difficulties were considered to put out of court all systems of electrification that involve the employment of screw propellers with aerial methods of electrification or otherwise, and electrically-propelled locomotives traveling on the towpath, that rely on their own weight for the necessary adhesion qualifications. The Thwaite-Cawley electric horse system, the motor of which travels on light superposed steel rails carried by vertical standards erected at intervals along the extreme boundary of the canal towpath, is considered by English experts to be a solution to the peculiar conditions of English canals, and to permit of high practical efficiency being obtained. Some elaborate tests have been made in a German canal with an electric system, which is apparently a modification by Ganz of the Thwaite-Cawley system, and this gave a 68 per cent. efficiency of haulage effort. The locomotive has a hauling capacity of 37.5 hp., and is capable of hauling barges of 600 tons burden. The average working cost per kilo mile is stated to be equal to 0.05 pence with current at 1.4 pence per kw. The cost of a kw. would in Fngland be less than this.

The electrical energy would, for trunk canals, be transmitted at high pressure and transformed to lower pressures for distribution. Gas power generating stations would be located every 20 miles in the length of the canal. The tow paths would provide the way leaves for laying the high pressure conductors which would serve for a general supply at cheap rates to all areas through which the canal traverses. The locks, gates and sluices could be electrically actuated and electric capstans would provide the necessary elasticity to the haulage system. Then, further, the warehousing, hoisting, and conveying machinery could also be electrically actuated.

In his estimate of the cost of nationalizing and electrifying the 3,500 miles of Great Britain, Mr. Thwaite assumed that they would be purchasable at two-thirds of their original cost of construction, say £2,850 per mile of length. Allowing £500 per mile for the cost of standardizing the locks, and £2,000 per mile for electrification, a total of £16,975,000 was arrived at. The round figure of 20 millions was mentioned as leaving something in hand for working capital. It was pointed out that the electrification would provide a cheap supply of electric power for export service, as well as for pumping, irrigation, plowing, churning, milling and vegetable and flower growth, and go far toward securing a revival of agricultural prosperity.

Many efforts are being made to induce the British Government to take the matter seriously in hand, but it is doubtful, with so many pressing calls, whether 20 millions can be spared under current conditions.

MARCONI ON WIRELESS TELEGRAPHY.

On Friday, March 3, at the Royal Institution, London, Mr. Marconi gave a lecture on "Recent Advances in Wireless Telegraphy." The audience included many men of distinction, among whom were Lord Kelvin, Lord Rayleigh, Sir James Dewar, Sir William Crookes and Prof. J. A. Fleming.

The recent improvements in wireless telegraphy, to which especial reference was made by Mr. Marconi, included the means to prevent interference and secure independence of communication; also the research and experiment which aimed at increasing the distance over which communication was possible, and the means of more accurate and efficient working. The "Times" (London) gives the following abstract of the lecture:

The difficulty that messages sent by wireless telegraphy were liable to interference appeared more serious to the public than to the expert telegraphist, who knew that the same thing was possible with ordinary telegraphy, but that it was prevented by rules and regulations devised to that end. In some cases—as of a shipwrecked vessel calling for assistance—it was a positive advantage that the messages should be received by a number of other ships or stations. But the liability to interference must in some cases be recognized as a drawback; and, accordingly, he had endeavored to discover means by which it could be prevented, the principle of which he briefly described. By having several stations tuned or syntonized to different periods it was now possible to send to each one of them without the others being affected, and even five years ago it was possible to send and receive several messages simultaneously without one interfering with another.

Passing to detectors, or receivers, Mr. Marconi referred to the older coherers and decoherers, and then to the magnetic detector, which he had devised more recently, and which, after two years' experience, he was convinced was a much superior appliance. It was now used in those ships of the British Navy which were fitted with Marconi long-distance apparatus. At first it had the disadvantage that it could not be made to actuate a recording or writing instrument, the current impulse with which it worked, though suitable for producing a click in a telephone, being too rapid and sharp to have any appreciable effect on the tongue of a relay. But now, by altering the circuits and the character of the iron employed in the magnets, the impulse had been slowed down, so that it was possible to work a relay, and, therefore, a recording instrument. With the new arrangement high speed was attainable, and also automatic sending, and it had been worked satisfactorily for a distance of 152 miles overland. As to the speed of his apparatus generally, Mr. Marconi claimed that in 1898 he was able to send an average of 12 words a minute, and between Amsterdam and Chelmsford he had more recently maintained an average of 24.

The lecturer next made reference to the progress which had been made in the direction of long distance working. After touching upon the big stations in Cornwall and America, he said that his preliminary experiments of 1901 convinced him of the possibility of trans-atlantic wireless telegraphy. In the spring of 1903 the transmission of American messages to the "Times" was attempted, but owing to breakdown of the apparatus it had to be discontinued, and it was decided not to attempt the transmission of public messages again until certainty was insured. New stations were now in course of erection and he had no doubt that in a short time it would be demonstrated that transmission across the Atlantic was practicable and trustworthy. Comparing wireless with cable telegraphy, he remarked that the cable companies had many cables, so that the public did not hear of the breakdowns that occurred, though they did in cases where there was only one cable, as to the Scilly Isles. Having referred to the long-distance news service maintained between the shore and several Cunard liners, Mr. Marconi said that the differences in transmission by day and by night were noticeable only when long distances were concerned, the range by day being much less than by night. Clear sunlight and blue skies, indeed, seemed to act as a fog to the Hertzian waves, but such things were not general in England, where, accordingly, the conditions were usually very favorable to wireless telegraphy.

He then spoke of some criticisms directed against his efforts at transatlantic telegraphy by critics who thought wireless telegraphy would find its proper sphere in providing communication between ship and ship and ship and shore, and went on to describe an apparatus invented by Prof. Fleming for measuring the length of electric waves. Finally, he gave some details showing the extent to which his system was used. He had, he said, every confidence that wireless telegraphy would be able to provide communication between England and her Colonies and England and America more economically than the submarine cable, and meantime it was gratifying that it had already done something towards increasing the comfort and decreasing the perils of those that went down to the sea in ships.

METAL ANALYSIS BY ELECTROLYSIS.

Before a recent meeting of the London Faraday Society, Mr. J. G. A. Rhodin read a paper on "Mass Analysis of Muntz's Metal by Electrolysis, and Some Notes on the Electrolytic Properties of this Alloy." He described—his paper being illustrated by experiments—an apparatus which was specially designed by him for the purpose of the accurate and rapid determination of the copper content (which should lie between 60.5 and 61.5 per cent.) of Muntz's metal.

As about 40 to 60 "heats" of metal are cast every day, and it being necessary to obtain the results within 12 hours of the time of casting, the apparatus had to be such as to enable 100 analyses to be made in 24 hours—with a mean probable error of not more than + or − 0.1 per cent. The author decided that an electrolytic method would best fit in with these stringent requirements.

The electrodes employed consist of concentric cylinders of very fine platinum gauze, supported by stout frameworks in order to insure even current distribution. The anode rests on a ring at the bottom of the containing vessel so that the cathode can easily be slipped away and removed, and both electrodes are held in modified Classen stands. The present installation consists of 30 such unit cells, and current is supplied to them from six pairs of accumulators, each of which supplies current to five pairs of electrodes through suitable nickeline resistances.

One gramme of the alloy, dissolved in nitric acid, is used for an analysis, and a current either of 0.5 ampere or else of 2.0 amperes is employed for the deposition. In the former case deposition is complete in 12 to 15 hours, in the latter in three hours. Electrolysis proceeds in three phases: (1) Copper deposition and ammoniacal reduction of nitric acid. (2) Ammoniacal reduction only. (3) Deposition of zinc. A perfect separation takes place if phase (2) occupies a long time and is unaccompanied by metal deposition. If certain impurities, such as arsenic or nickel, be present they must be removed chemically. The paper described in detail the actual procedure at the works laboratory, and also included a table showing the kind of accuracy obtained in cases where re-analyses have been made. Since these analyses in bulk have been made it has been found that they act as an infallible guide to the casters, so that remelting has now become very rarely necessary.

In conclusion, the author discussed the electrochemical properties of Muntz's metal. The metal is largely used as a sheathing to protect ships' bottoms from certain mollusca and algæ, and to be successful it should dissolve in sea-water just to a sufficient extent as to render the surface poisonous, the best conditions being the equal dissolution of the copper and zinc. The author shows how these may be calculated approximately by supposing that the electrolytic dissolution rate is proportional to the heat of formation of the ultimate compounds (zinc and cuprous chlorides) and to the conductivities of the metals which dissolve. Assuming that both the chlorides of copper are formed, and taking the mean of the results in the two cases, the best values are found to be 60.811 per cent. of copper, and 39.189 per cent. of zinc, numbers which agree very closely with the results of practical experience. The author is now engaged in exhaustively investigating the absolute dissolution-velocity of pure Muntz's metal at a definite temperature, and he adds here a preliminary description of these experiments, describing in an appendix his most recent experiments on the subject. He finds that a binary alloy like Muntz's metal dissolves slowly at first, the velocity then quickly arrives at a maximum, then it falls suddenly—remaining almost constant for some time—and finally a more or less rapid fall again occurs. During the period of constant velocity the surface must alter as the resistance capacity, if the action is galvanic. The seat of the EMF. must be in the electrolyte, as the constancy of action indicates a steady EMF. of considerable magnitude. It is probable that the result is influenced by the actual mass of metal present, relative to that of the solvent. The external pressure certainly exercises a very considerable effect on the reaction-velocity, by influencing the speed with which hydrogen can leave the surface of the metal. The author promises further communications on the subject.

ELECTRIC LIGHTING TROUBLES WHICH MIGHT BE AVOIDED.

BY ALFRED H. MAYES.

Those who have had considerable experience of electric lighting installations can scarcely fail to have observed that the causes of breakdown or other trouble are comparatively few in number, and, consequently, the same class of fault presents itself again and again. Short-circuiting in lamp-holders is a prolific source of destruction to lamps, and frequently of far more serious damage. The cause is generally a stray strand from the end of the duplex conductor, which finds itself free from the remaining strands and manages to make contact with the opposite pole. The remedy for this trouble is simply to exercise more care in fixing the bunches of fine strands in their respective terminals. By far the most satisfactory plan is to burn off the insulation, which can be done without injuring the wires in the slightest degree, and then to tightly twist the strands into the semblance of a solid conductor, using the finger and thumb only for the operation. Should the pliers be brought into requisition for this purpose, the fine wires will certainly be bruised or broken, and the difficulty we are seeking to guard against will result.

The difficulty of obtaining a sufficiently high insulation resistance between the poles of the whole installation is not an unusual trouble, and is sometimes due to a little-suspected cause—that is to say, the employment of a cheap class of poorly-insulated duplex cord in some of the fittings. When one realizes that the positive and negative poles of the system are closely twisted together, the necessity of high class flexible cord is at once apparent, especially so in damp or exposed positions.

Serious loss and annoyance to users of the electric light is frequently caused by the "blowing" of sub or main fuses. Whilst fully recognizing the importance of not providing too much carrying capacity in fuses, it must also be borne in mind that if the capacity is cut too fine, that the premises may be plunged into darkness owing to a momentary and trifling increase in the supply voltage, and this frequently happens, causing much difficulty to the unfortunate consumer, who frequently has trouble in obtaining the services of an electrician to put matters right, especially should it occur late at night.

As anything tending to bring electric lighting into disrepute is strongly to the disadvantage of wiring contractors, attention to the foregoing hints will be amply repaid by increased satisfaction to uses.—"Electrical Engineer," London.

Marconi Married.

Mr. William Marconi was married on Thursday last at the Catholic Church of St. George, in London, to Lady Beatrice O'Brien. Lady O'Brien brings to her husband a dowry of $30,000 a year.

American Institute of Electrical Engineers.

The 195th meeting of the American Institute of Electrical Engineers will be held at the chapter room, Carnegie Hall, 154 West 57th street, New York, on Friday, March 24, at 8:15 P. M. The following papers will be presented and discussed:

"Line Construction for High-Pressure Electric Railroads," by George A. Damon.

"High-Pressure Line Construction for Alternating Current Railways," by Theodore Varney.

"Application of High Pressure to Electric Railroads," by Ernest Gonzenbach.

March Reunion of Society of Mechanical Engineers.

The March reunion of the members of the Society of Mechanical Engineers in New York will take place on the evening of Tuesday, March 28, at 8:15 o'clock. The paper of the evening will be entitled "Formation of Anchor Ice and Precise Temperature Measurements," by Dr. Howard T. Barnes, assistant professor physics, McGill University, Montreal.

Pushing Business on the Coast.

The Standard Underground Cable Company announces that, on account of the general growth of its business on the Coast, it has decided to discontinue all agency arrangements for the sale of its products, and on April 1 will open its new offices in the Rialto Building, San Francisco, with Mr. A. B. Saurman as manager for the Pacific Coast territory, which includes Washington, Oregon, Idaho, California, Nevada, Arizona, British Columbia, Alaska and the Hawaiian Islands. Mr. Saurman has in turn been connected with the Standard Underground Cable Company in both construction and sales departments at Philadelphia and New York, and was later for several years manager of the Boston office, while for the past two years his position has been that of manager of the Pacific Coast sales department.

The Standard Underground Cable Company expects to make early announcements of location and personel of sub-sales offices at Los Angeles and Portland. It also reports that its factory at Oakland, Cal. (the only factory west of the Mississippi equipped with lead presses for cable work), has been unusually busy during the past six months, and that the future on the Coast points to its continued activity.

"Diamond H" Automatic Flush Receptacle and Plug.

Flush Recptacles and Plugs are a convenient means of obtaining current for various purposes, such as portable lights, fan-motors, etc., in different parts of the room.

At the time of building and wiring a house, the exact location of pieces of furniture requiring a good light, as tables, desks, pianos, etc., is uncertain. Therefore, the installation of several receptacles in the base board of a room will be very advantageous in that it permits the placing of a piece of furniture anywhere in a room—so far as obtaining light for same is concerned.

After the location of the receptacles is determined, there remains the selection of that receptacle which can be used with the least trouble to the operator; and which, when not in use, will be automatically closed, with no chance of accidental opening, and into which metal things of all sorts cannot be inserted by the inquisitive small boy—with unpleasant and oftentimes painful consequences.

Two features of almost equal importance with the automatic closing of the holes in the face-plate, are the automatic opening of same by the simple insertion of the plug in making the connection, and a construction which renders the accidental grounding of the circuit on the face-plate, when making the connection, impossible.

The use of one hand, only, in making the connection, is another desirable feature.

The "Diamond H" Flush Receptacle and Plug, manufactured by the Hart Mfg. Co., of Hartford, Conn., seems to embody all of the features necessary for a perfect device, and its specification by architects and engineers will result in the same eminent satisfaction to the user that "Diamond H" switches have always afforded.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED MARCH 14, 1905.

Electric Railways and Appliances.

784,639. Electrical Trolley. Seneca R. Stoddard, Glens Falls, N. Y. Filed March 21, 1903. Renewed Aug. 12, 1904.

784,678. Trolley Catcher and Retriever. William W. Hoffman and Francis W. Powers, West Lafayette, Ind., assignors to the Electric & Steam Railway Supply Company, same place. Filed Sept. 23 1904.

784,681. Trolley-Guide. John F. Jameson, Plimpton, O, Filed Dec, 21, 1904.

784,741. Insulated Rail-Joint. George L. Hall, New York City. Filed Jan. 9, 1904.

784,814. Railway-Motor Control. Charles P. Steinmetz, Schenectady, N. Y., assignor to the General Electric Company. Filed Aug. 20, 1904.

784,843. Trolley. Michael O. Day, Newcastle, Pa. Filed Dec. 20, 1904.

784,865. Electric Train Signaling Equipment. W. Britton Lane, Evanston, Ill. Filed Dec. 21, 1904.

Electrical Machinery and Apparatus.

784,547. Brush-Holder for Dynamo-Electric Machines or Motors. John F. Card, Three Rivers, Mich., assignor to the Sheffield Car Company, same place. Filed Oct. 1, 1903.

784,555. Junction-Box for Electrical Conductors. John Fountain, Jr., Elizabeth, N. J. Filed Nov. 13, 1902.

784,626. Electric Sparking Igniter for Explosive-Engines. George McCadden, St. Cloud, Minn., assignor to Frank Zins, same place. Filed June 22, 1903.

784,680. Sewing-Machine Motor Attachment. Francis P. Huyck, Swanton, O. Filed June 4, 1903.

784,712. Electric Central-Station Recording Mechanism for Meters. Chester H. Thordarson, Chicago, Ill. Filed Oct. 28, 1903.

784,718. Electric Solenoid. Ludwig S. Walle, Brooklyn, N. Y., assignor to Fridtjof Jebsen, Bergen, Norway. Filed Dec. 29, 1903.

784,807. Dynamo-Electric Machine. Henry G. Reist, Schenectady, N. Y., assignor to the General Electric Company. Filed Aug. 1, 1904.

784,869. Electric-Elevator Control. Niles O. Lindstrom, Jersey City, N. J., assignor to Alonzo B. See and Walter L. Tyler, New York City. Filed Nov. 17, 1904.

Telephones and Telephone Apparatus

784,546. Coin-Operated Telephone-Locking Device. William Calhoun, New York City, assignor, by mesne assignments, to the National Telephone Lock Company. Filed Sept. 18, 1903.

784,557. Telephone-Call. Peter T. Geyerman, Brewster, Minn. Filed April 29, 1904.

784,588. Party-Line Selective System. Frank P. O'Conor and Frederic McNeill, Lasalle, Ill. Filed Feb. 13, 1904.

784,605. Telephone-Operator's Key. Louis W. Wanemaker, Genoa, Ill. Filed May 11, 1904.

784,635. Relay. Micheal Setter, Chicago, Ill., assignor to the American Electric Telephone Company. Filed April 5, 1902.

784,720. Telephone Signaling Means. Klas Weman, New York City. Filed June 4, 1904.

Miscellaneous.

784,529. Telegraphic Transmitter. Martin Armstrong, St. Louis, Mo. Filed Dec. 29, 1902.

784,592. Apparatus for Effecting Electrolysis. Herbert Philipp, Wyandotte, Mich. Filed Aug. 10, 1903.

784,617. Electroplating Apparatus. Herman Fleischer and Charles H. Fleischer, New Britain, Conn., assignors to the Stanley Works, same place. Filed May 23, 1904.

784,732. System of Electrical Distribution. Rufus N. Chamberlain, Depew, N. Y., assignor to the Gould Storage Battery Company, New York City. Filed June 12, 1903.

784,766. Electric-Conductor Union. Frederick W. Sorg, Englewood, N. J. Filed Aug. 17, 1903.

784,790. Guide for Battery-Stems. Charles F. Hawley, Heppner, Ore. Filed April 23, 1904.

784,858. Combined Typewriter and Telegraph-Transmitter. Cyrus H. Hepinstall, St. Thomas, Canada. Filed Feb. 1, 1904.

784,860. Traingraph. William A. Inwood, Colorado Springs, Col. Filed Aug. 16, 1904.

784,885. Method of Extracting Metals from Ore by Electricity. Edward L. Priest, Oakland, Cal. Filed April 5, 1904.

Reissue.

12,324. Trolley-Wheel Guard for Electric Wires. John L. Sullivan, Warren, R. I., assignor of one-half to Joseph Harris, same place. Filed Jan. 26, 1905. Original No. 777,049, dated Dec. 6, 1904.

THE TELEPHONE WORLD.

Independent Men Meet in Binghamton.

A recent meeting of Independent telephone men of the Binghamton district of the New York State Independent Telephone Association was held in that city. George B. Wright, of Binghamton, was made temporary chairman, in pursuance to a call of the New York State Association, and for the purpose of organizing the Binghamton district association.

This district comprises the various Independent telephone companies operating and doing business in Cortland, Chenango, Broome and Delaware Counties.

The organization is made up of practical telephone men and flattering reports were received, covering the growth financially and physically of the various interests represented,

The following companies were represented: Nanticoke Valley Telephone Company, Gurney Smith; Killawog Telephone Company, C. K. Tarble; Lisle Rural Telephone Company, M. L. Sternberg; Marquis Telephone Company, J. B. Marquis; Whitney Point & Glen Aubrey Telephone Company, C. E. Slacker; Delaware Valley Telephone Company, C. B. Teed; Riverside Telephone Company, George Hyatt; Chenango Valley Telephone Company, Fred M. Harding; Lester Telephone Company, H. A. Williams; York State Telephone Company, George B. Wright.

It was reported that nearly 6,000 Independent telephones are in operation in the Binghamton district and that extensive building of new lines, in addition to those already under construction, is planned everywhere.

Officers were elected for the ensuing year consisting of J. B. Marquis, Jr., Norwich, chairman; F. M. Harding, Chenango Bridge, vice-chairman; M. L. Sternberg, Lisle, secretary and treasurer.

The next regular meeting of the Binghamton district will be held April 18.

The Grand Prairie Telephone Company was lately organized at Carlisle, Ark., the officers being as follows: E. C. Holt, of Lonoke, president; H. I. Buechley, of Carlisle, secretary and treasurer; J. E. Tunis, of Carlisle, general manager. The new company will incorporate at once, and build a line from Hazen to Carlisle, for both local and long-distance service, and will control a solid metallic circuit of two wires between Carlisle and Lonoke, for toll service only, which will connect at Carlisle with the Jacksonville Telephone Company, thus affording service with all the subscribers of the 'phones of this company, and giving a long distance line to Little Rock. The company expects to unite with another Independent company at Hazen, which will give connection with DeVall's Bluff and Stuttgart in the near future. All the poles are up between Lonoke and Hazen, and the wire will be in place shortly. Other wires will be strung on the poles for the use of Carlisle subscribers.

The Northwestern Telephone Company will spend some $25,000 in improvements in Owatonna, Minn., during the coming summer. A complete new battery system will be installed.

The Farmersville O., Telephone Company has amended its charter enlarging its purpose.

Nebraska Has Another Independent Company.

The organization of the Kearney Telephone Company has been completed and the officers of the company are: T. E. Parmelee, president; Warren Pratt, vice-president; W. S. Clapp, secretary and treasurer; W. J. Stadelman, general manager. These with F. H. Gilcrest constitute the board of directors. The new corporation has acquired the plant and business of the Home Telephone Company, the Kearney and Northwestern Telephone Company, and the Overton Telephone Company, all three of which systems will be operated in conjunction and under one management; the toll lines east and west are to be equipped with copper wire and other improvements are to be made, which will make the system one of the best and most profitable in the State.

It has been announced that after April 1 the telephone rate to all boroughs in New York City on calls from public telephone, will be 10 cents. There will also be a reduction in charges to subscribers. The Merchants' Association is informed that there will be no legislative investigation of telephone charges in the city.

The telephone monopoly in Connecticut, represented by the Southern New England Telephone Company, was drawn and quartered by the Glastonbury Business Men's Association at a recent meeting. In addition to speaking freely about that concern, steps were taken to assist the rival company, which has been trying to get into that State to accomplish its purpose. The Glastonbury representatives will go before the Legislature with their grievances.

At an adjourned special meeting of the stockholders of the Mexican Telephone Company, it was voted to sell the company's plant to the Mexican Telephone & Telegraph Company. The latter concern was recently organized under the laws of the State of Maine.

It is said that the Markles, of Hazleton, Pa., will have a large interest in the reorganization of the Keystone Telephone Company. It is proposed to put out a new bond issue that will take up all floating debt.

A dispatch from Toronto, Ont., says that 35 telegraph operators of the Middle and Eastern Divisions of the Grand Trunk Railway have received notice of dismissal. The company, it is said, will adopt the composite telephony system.

At a meeting of the citizens of Trimble County, in Milton, Ky., it was decided to form an Independent telephone company to connect Bedford and Milton and other points in the State. The capital of the concern will be $15,000.

The New England Telephone & Telegraph Company will ask the Lowell, Mass., city government for permission to place the remainder of its wires in that city underground.

The Farr Telephone & Construction Supply Company, of Chicago, Ill., has increased its capital from $10,000 to $25,000.

United States Telephone Company.

The directors of the United States Telephone Company, of Cleveland, O., have declared the regular annual dividend of 6 per cent. on the preferred stock, payable quarterly. The following officers were chosen: F. S. Dickson, president; H. A. Everett, vice-president; James B. Hoge secretary, and R. W. Judd, treasurer. Mr. Everett succeeds E. W. Moore as vice-president.

Directors of 15 rural telephone lines covering the western half of Steuben County, N. Y., have entered into an agreement with the Century Telephone Company, whereby the rural lines will be centered in the Bath Century office, establishing connections with the toll and village lines, as well as affording communication from one rural line to another.

The Robinson Telephone Company has been incorporated with the New York Secretary of State to operate in St. Lawrence and Franklin Counties. The capital is $10,000, and directors: T. J. Robinson, of Potsdam; W. F. Robinson, of Addison, Vt., and Lindley Robinson, of Crary Mills.

The Iowa Telephone Company is planning the erection of a new exchange building in Sioux City during the coming summer. E. A. Clark, manager of the company has made the positive statement that the company, would be housed in its own exchange building by next November.

The controversy in which the Sioux City, Ia., Telephone Company, Bills Bros. and the General Engineering Company have been mixed, has been settled, and announcement is made that within 90 days the people of Sioux City will be talking over the new automatic telephones.

A new telephone system has been installed at Haskell, I. T., a new town on the Midland Valley Railroad. A toll line will be connected with Muskogee.

The Providence, R. I., Telephone Company is planning for a new telephone exchange building in East Providence.

The Glen Telephone Company is preparing to install an addition to its switchboard in Canajoharie, N. Y.

The Rural Telephone Company has obtained the right-of-way through Glassboro and Clayton, N. J.

Telephone Incorporations.

The Unity Township Telephone Association, East Palestine, O. Capital stock, $8,000. Incorporators: J. F. Johnston, M. W. Beyer, Everett L. Lyon, J. S. Kirball and J. J. Rukenbrod.

The Franklin Farmers' Co-operative Telephone Company, Farmington, Me.—to construct a telephone line, etc. Capital stock, $10,000. Officers: President, H. H. Devoe, Farmington; treasurer and clerk, F. E. Voter, Farmington.

The East-Wood Telephone Company, Elmore, O. Capital stock, $50,000. Incorporators: J. G. Steinkamp, Homer Metzgar, Taylor Fuller, Fred Windisch and George W. Luckey.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Arcanum, O.—At a recent election the people voted to issue bonds to the amount of $38,000, for building waterworks and electric light plants.

Benton Harbor, Mich.—The Michigan Cold Storage & Transfer Company will build an electric light plant with sufficient capacity to provide light for this city.

Bristol, Tenn.—This city has granted a franchise to Edward Durham, of Philadelphia, Pa., and William B. Cutler, of Buffalo, N. Y., to construct and operate an electric light plant.

Cassville, Wis.—A special election will be held March 30 to vote on the electric light question.

Centerville, Ia.—A mutual electric light company is projected and will seek a franchise at the election March 27.

Centerville, Md.—This city is to have an electric light and gas plant in the near future. D. S. Pindell, of Michigan, representing the Buner Electric Light Company, has conferred with the board of town commissioners and a contract has been signed.

Cheshire, Conn.—This town contemplates erecting an electric plant of its own. A committee, consisting of R. H. Morgan, J. M. Speake and Ira D. Woodley has been appointed to ascertain just what such a plant would cost.

Covington, Ga.—The city council contemplates re-establishing the city electric light plant, which was destroyed by an explosion.

Elkhart, Ind.—Ex-Congressman C. G. Conn's new electric light plant and hydraulic properties were damaged to the extent of several thousand dollars by a serious washout of a race bank.

Ephraim, Utah.—The city council will be requested to call a special election to vote on the issuance of bonds to the amount of $20,000 for the erection of a power and electric light plant.

Gainesville, Ark.—The Gainesville Gas & Electric Company, with a capital of $100.000, has been incorporated by Charles W. Moore. Jeremiah Cushman and others, to operate a gas and electric light plant.

Gravette, Ark.—This city contemplates constructing waterworks to cost from $8,000 to $10,000; also the establishment of an electric light plant is being considered. A. C. Veach may be addressed.

Lone Oak, Tex.—It is reported that W. L. Harrison is arranging for the installation of an electric light plant.

Lyndon, Ill.—A franchise has been granted to H. F. Breen and others to construct a dam here. An electric plant is to be built in connection at a cost of $150,000.

Marietta, O.—The county commissioners are considering the matter of installing an electric light plant at the court house.

New Franklin, Mo.—A special election has been called for March 27 to vote on a proposition to grant a franchise for an electric light plant to be erected and operated by a local company.

Onalaska, Wis.—Mr. Stinson, of West Salem, has applied to the council of this city for a franchise to furnish electric lights here.

Oolitic, Ind.—The town board has decided to build a combined waterworks and electric light plant to cost about $23,000.

Petros, Tenn.—The Big Brushy Mountain Coal & Coke Company, which recently installed an electric light plant at its mines, is arranging to furnish this town with lights. A. H. Wood, of Harriman, is president.

Red Oak, Ia.—The Electric Light Company will increase the capacity of its plant.

Rosedale, Miss.—The city council at a recent meeting appointed a committee to get prices on an electric light plant, same to be run in connection with the waterworks and owned and operated by the city.

Sodus, N. Y.—The Sodus Gas & Electric Light Company contemplates establishing an electric light plant. George L. Colgate is the engineer in charge.

Sonora, Tex.—Hurst Brothers are arranging for the establishment of an electric light plant.

Vallejo, Cal.—The California Gas & Electric Company, of this city, has succeeded the Vallejo Gas Light Company, and will expend $25,000 in improving the system here, which will be extended to every portion of the city.

Virden, Ill.—The city council has granted a 20-year franchise to C. W. Carr for the erection of an electric light plant.

West Burlington, Ia.—The citizens will vote on the question of establishing a municipal electric lighting plant.

West End, Ala.—The city council has granted an electric light franchise to the Birmingham Railway, Light & Power Company.

STREET RAILWAYS.

Auburn, N. Y.—The common council has granted to the Auburn & Northern Railroad Company, in which C. H. Beebe, of Syracuse, is interested, permission to lay tracks in Dill and other streets. This 9-mile double-track line to Port Byron will connect the Rochester, Syracuse & Eastern and the Auburn & Syracuse railroads.

Colfax, Wash.—The Whitman Electric Railway & Power Company, which is planning an electric railroad from here to Palouse, has begun grading the roadbed.

Columbia City, Ind.—The proposed electric road from here to Goshen is being surveyed.

Edwardsville, Ill.—An ordinance granting a franchise to the Edwardsville, Alton & St. Louis Railway Company has been passed by the city council of Edwardsville. The grant provides that an electric line may be built through the western part of the city, and eight miles to Mitchell.

Frankfort, Ky.—The Central Kentucky Traction Company, with $200,000 stock, a Fayette County corporation, lately filed articles with the Secretary of State.

Greenville, Tex.—J. M. Waits, representing a company of Dallas is contemplating the erection of an electric interurban trolley line from this city to Bonham.

Indianapolis, Ind.—This city will grant a franchise to the Indianapolis, Newcastle & Toledo Traction Company.

Kankakee, Ill.—The Kankakee & Western Electric Company, of this city, capitalized at $15,000, has been formed to construct electric railroads.

Little Rock, Ark.—L. Garrett has been looking over the field here with a view to building an interurban electric line between this city and Hot Springs. He has begun preparations for the organization of a company to carry the project through.

Manitowoc, Wis.—The Fox River Valley Railway Company proposes to construct an electric interurban line from Sheboygan to this city and then to Kaukauna.

Mt. Sterling, Ky.—It is reported here that the recently incorporated Olympian Springs Company, of Lexington, will build an electric car line from the Chesapeake & Ohio road to the springs and extend it into the mountains to West Liberty.

North Baltimore, O.—S. O. Douglass, of Toledo, has lately been in this section in the interest of a new trolley line from Fostoria to Deshler.

Paw Paw, Mich.—Dunkley & Williams are preparing to erect a trolley line from South Haven to Kalamazoo, to be operated in conjunction with the Dunkley-Williams steamboat line between South Haven and Chicago.

Schenectady, N.Y.—It is said that the Schenectady Railway Company expects to build a complete trolley system in Saratoga Springs.

Winona Lake, Ind.—The Winona Interurban Railway Company of this place will erect a new power house at a cost of $600,000.

POWER PLANTS.

Columbus, O.—Prof. B. F. Thomas, of the Ohio State University, has prepared plans for a new power plant to be erected at the Dayton State Hospital.

Ft. Gibson, I. T.—It is reported that a $1,000,000 plant will be built on the Grand River for the transmission of power by electricity. Surveys are being made under the supervision of D. W. Bolich, engineer.

Montgomery, Ala.—The Tallapoosa Water Power & Electric Company has been incorporated by Ausfeld & Chapman, of this city, and others The company will shortly commence the erection of its proposed plant to cost $500,000.

Mountain Home, Idaho,—J. E. Jerome, W. J. Turner and J. H. Garrett, of this place, are organizing a company with a capital of $500,000, and will build a power plant at Crane Falls for the purpose of furnishing this town and Bruneau with electric power and light.

Salt Lake City, Utah.—It is reported that the Utah Light & Railway Company contemplates constructing a power plant. R. S. Campbell is general manager of the company.

BIDS WANTED.

Baltimore, Md.—The Eastern Flint & Spar Company, 616 North Calvert street, this city, wants prices on a 100 hp. engine.

Des Moines, Ia.—Sealed bids will be received by N. B. Vertrees, city clerk, until March 31, for electrical supplies, etc.

Lincoln, Neb.—The water commissioner has been instructed to secure bids on a 75 hp. vertical alternating electric motor for use at the pumping station.

Springfield, Tenn.—Dulin, Glenn & Co., of this place, want prices on electrical equipment.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 15⅛@15¼c.; Lake 15¼@15⅜c.; casting, 14⅞@15c.

The Toledo (O.) Railway & Light Company reports for February a surplus increase of $10,858.

Orders on the books of the Electric Storage Battery Company are said to be double those at this time last year.

The belief is quite general that the Massachusetts Electric Companies will resume 4 per cent. dividends upon its preferred stock this summer.

The New York franchise tax cases will be called for April 3, for argument in the Supreme Court at Washington. The sum involved is about $21,000,000.

President Winter of the Brooklyn Rapid Transit Company says that the company has decided that an elevated loop is the only solution for the congestion of the Brooklyn bridges.

The Haverhill (Mass.) Electric Company has been authorized to issue 1,071 additional shares of stock at $160 a share for the purpose of funding the debt incurred in extensions of the plant.

An official of the Allis-Chalmers Company says the outlook for business this year is very gratifying, but no one connected with the company will attempt to discuss dividends on the stock.

For the purpose of paying the regular quarterly dividend of 1 per cent. on May 1, the tranfer books of the Detroit United Railway Company will close at noon April 15 and reopen May 2.

On June 1 there will be delivered to the Brooklyn Rapid Transit system $2,500,000 of new equipment. The delivery of this equipment will be in time for the company's heavy summer business and it should have considerable bearing upon earnings.

The Interborough Rapid Transit Company of New York has declared a quarterly dividend of 1¾ per cent. on its capital stock, payable April 4. The declaration puts the stock on a 7 per cent. basis, although it had been thought an 8 or 10 per cent. basis would be established.

The Boston & Worcester Electric Railway Company is preparing for the installation of a freight and express service upon its line. It is estimated that this will require an equipment of five cars that will cost $4,000 each. With this equipment express experts claim that the company can do a gross business of about $125,000 per annum and that it will cost about 40 per cent. of gross to get it.

The Baltimore pool which is in charge of Alexander Brown and George C. Jenkins, as trustees of the common stock of the United Railways & Electric Company of Baltimore, has closed and it is said that considerable over a majority of the stock was deposited. The agreement is for three years, and one of the provisions is that the trustees may sell the stock on terms approved by 75 per cent. of the shares deposited.

Kidder, Peabody & Co., of Boston, and Baring Bros. & Co., Limited, of London, are offering for public subscription, at 96½ and accrued interest, the balance remaining unsold of an issue of $25,000,000 American Telephone & Telegraph Company collateral 4 per cent. gold bonds, dated July 1, 1889, and maturing July 1, 1929. Subscription lists will be opened on Tuesday, March 21, at 10 A.M., and closed at or before 3 P.M. on the same date.

EDITORIAL NOTES.

Electric Railways Across the Continent.

Reviewing present accomplishments from a general standpoint, it is evident that a distinct evolutionary process has taken place, which has been the means, although for the most part unconscious to ourselves, through which the work of the past, the success of the present, and the experiments of the future form parts of one vast chain of events in the field of electric railroading. For at least one generation, Van Depoele, Daft and Sprague struggled with the chaotic conditions confronting them. What had been accomplished was done with a certain arbitrariness, in which the success of the motor, the transmission and distribution of power, and in total, the success of the electric car as a whole were but parts of one confusing problem. Time has helped to sift these matters, aided by the genius and self-sacrifice of many workers, and it seems, as we have stated, that the subdivisions of this great task slowly came to light. The motor, the track, the trolley, the gearing and the power house with its varied equipment separated themselves into single departments of one general proposition, and thus called into being the attention of the subordinate workers with their improvements in incidentals and details. The facts settled upon related to the general equipment of the car, the horse power, trucks, speed, etc.; the installation of the tracks and overhead trolley or of the third-rail, its electrical equivalent; and, finally of the design of the station, with its engines, boilers and 500-volt generators. This, in the aggregate, represents the first chapter of this interesting history.

The next step was the introduction of alternating currents to facilitate the delivery of power with an economy which invited further extensions and greater developments. Niagara now turns the wheels of all cars in Buffalo, and wherever power is available in sufficient quantity it can be transmitted and distributed economically for electric railway, power and lighting service. This, it seems, is the second stage of the problem or the second great chapter of the new volume of electric railroading.

The third development in this field is unique. It is the crystallization of old ideas in a new enterprise, and presents some startling possibilities in the light of recent experiments. The series-wound motor has long been known to operate well with a single-phase alternating current. By laminating the iron of such a motor, it is capable of developing power with great efficiency. The application of this motor, which is practically the type of motor now employed, but supplying it with an alternating instead of a direct current for electric car service, may lead to the use of transcontinental electric lines in this country. Pressures of nearly 20,000 volts, or about 40 times that now in use, can be employed to run electric cars.

The simple equipment of the car itself, and the great saving in the station, makes it one of the most alluring propositions ever brought before a board of financiers. The sub-station, the rotary converter and a great variety of adjuncts can be entirely dispensed with. The radius of action of a street railway system alone may be enormously increased, and the first cost of installation proportionately greatly reduced.

Electric railways for trans-continental purposes can come into existence as soon as the practical pressure at which they can be worked is settled. This uncertainty is being rapidly dispelled by a systematic line of experiments by one of our largest engineering concerns. Another decade will not pass before New

York, Buffalo and Chicago are stopping places for our great electric train service, reaching far into the western slopes.

* * *

A Reduction in Telephone Rates. After years of struggle against the exorbitant rates of the New York Telephone Company relief is in sight.

The Telephone Trust in this city has seen fit to hearken to the demands of the people and announces that, beginning May 1, a new and more equitable schedule of telephone rates will go into effect. An officer of the company states that all direct line business subscribers will be charged the new schedule of rates, regardless of the rates named in the contract now existing between the subscribers and the company. These rates, which are given in detail on the telephone page of this issue of ELECTRICITY, range from 10 to 20 per cent. less than those now in force.

The reductions are supposedly made on the basis that the New York Telephone Company is willing to reduce its net earnings, so that the latter will be 10 per cent. on the capital actually invested, instead of the 14 per cent. it earned last year.

There will also be a reduction of tolls between the boroughs, those from Manhattan and the Bronx being given on page 184 of this issue.

The citizens of Greater New York should feel elated that the New York Telephone Company has at last been driven from the position it has maintained for ten years—that of a monopolistic dictator, which would not feel the force of public sentiment, and give those dependent upon it fair and equitable treatment.

* * *

The Search for Platinum. Owing to the increased demand for platinum, especially in the electrical industry, the United States Geological Survey is about to make an examination of the platinum resources of the United States. It is proposed to collect the heavy sands from all placer mines in the United States where evidences of platinum have been observed. The samples thus obtained will be used in determining the best methods of extracting the various minerals which have economic value. It is hoped that the separation and sale of these useful minerals, such as magnetite, chromite, garnet, monazite, rutile, zircon, gold, platinum, etc., will, in many places, become a permanent and profitable industry.

As a preliminary step to this investigation, the Survey invites the owners of placer deposits to contribute for examination samples of material likely to contain platinum. These samples, which should be sent by mail, must weigh not more than four pounds each. It is suggested that the gravel be concentrated before it is mailed. Careful note should be made on the package, or in a letter accompanying it, of the total quantity of original gravel which the concentrate represents, in order that an accurate idea may be obtained of the value of the gravel for the purposes under investigation. The sand should be dry when mailed and great care should be exercised to pack it securely, preferably in canvas bags, for transmission through the mails. Each package of sand should be accompanied by exact information as to the name and postoffice address of the sender, the name of the mine or claim from which it came, and the State, county, city, village or district in which the deposit is located.

After the Survey has made an examination of these samples, experts will be sent to all localities where preliminary tests give evidence of platinum. The expert will report on the size of the deposit and superintend the collection of representative samples for concentration. Experiments in the concentration of platinum sands will probably be carried on in connection with the exhibits of mining machinery at the Lewis and Clarke Centennial at Portland, Oregon, between June 1 and October 15 of this year.

Native platinum has been found most frequently in gold-bearing sands. On account of its weight it remains in the sluices with gold and other heavy material. It is most readily distinguished by the following characteristics:

(1) Its great weight. In panning it remains behind even gold in the pan.

(2) Its white color. It is whiter than lead and is distinguished from amalgam by its smooth surface, whereas the surface of amalgam as seen under a good glass is rough.

Platinum seems to be more generally distributed through California than through any other State. It has been found in Butte, Del Norte, Humboldt, Mendocino, Placer, Plumas, San Luis Obispo, Santa Barbara, Santa Cruz, Shasta, Siskiyou, Tehama, Trinity and Yuba counties. Curry, Coos, Lincoln and Josephine counties in Oregon have produced platinum. It has been discovered in Nez Perces County, Idaho.

◆

The annual convention of the American Institute of Electrical Engineers will be held at Asheville, N. C., June 19 to 23.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

Mr. William Marconi sailed on Saturday from Liverpool for New York.

◆

In this issue of ELECTRICITY will be found an advertisement from the New York Civil Service Commissioners regarding the appointment of an electrician. Applications for the position will not be received after April 4.

◆

Secretary Farrand informs us that a large number of inquiries have already been received regarding hotel accommodations for delegates attending the 28th convention of the National Electric Light Association, to be held at Denver-Colorado Springs June 6-11 next. He requests that all such inquiries should be addressed to the committee on hotel arrangements, 405 17th street, Denver. The personnel of the committee includes Mr. W. J. Barker, chairman; Messrs. J. Hernan, J. J. Cooper, J. F. Vail, S. W. Cantril, H. L. Woolfenden, Philip Cross, and J. C. Andrews, secretary.

◆

Sir Oliver Lodge, principal of the University of Birmingham, according to a cable dispatch from London, lectured Friday evening on what he described as a pertinacious electrical current. Stripped of technicalities, he said it could be described as a persistent current which would overcome great obstacles and go in any direction regardless of what stood in the way. He had been looking for such a current since 1884 and had only recently encountered it. He had applied it successfully in his prolonged experiments for dispersing fogs.

◆

In a paper read before the Tramways & Light Railways Association at Birmingham, the cost of building electric railways in England was stated to be from $20,000 to $30,000 per mile.

◆

A dispatch from Worcester, Mass., says that the New Haven Railroad Company is seeking to add the Worcester Consolidated Street Railway Company to its electric traction properties. The apparent purpose of this acquisition is the building of a through trolley line from New York to Boston running parallel with the Boston & Albany out from Boston as far as Springfield, following the New Haven the rest of the way to New York. To obtain possession of the Worcester Consolidated, control of the Worcester Railways & Investment Company, which is a voluntary association formed in 1901, and which owns 35,490 shares of the Consolidated Company, must first be obtained.

AN INTERNATIONAL EXHIBITION IN ITALY.

An exhibition is to be held next year—1906—at Milan in a sense to celebrate the opening of the Simplon Tunnel to passenger traffic, and it has already been postponed for two successive years. The locality of the exhibition is one which will add much to its success as a show. It will induce the visitor to travel by a new international route, which in Italy skirts the Lake Maggiore and in Switzerland the Lake of Geneva, while a circular tour can be made in going or returning by the Gotthard Tunnel.

The "transport" section of the exhibition comprehends every form of transit by land, by water and by air. It is divided into ten principal divisions. Division No. 1 relates to roads and highways, roadmaking, paving and maintenance. Division No. 2 treats of road vehicles for horse traction, conveying passengers and goods; also miscellaneous urban transports of every kind. Division No. 3, cycles and cycling. Division No. 5, railways, is a most important section, but from which electrical transport is excluded. Like all the other divisions, it is divided into groups, subdivided into classes Division No. 6 is devoted to electrical transports. In Division No. 7 all kinds of aeronautical apparatus will be exhibited. Division 8 is devoted to different forms of telegraphy and telephony. Division 9 is given up entirely to the Simplon Tunnel and is divided into three groups. Group 1, details—scientific, historical and commercial. Group 2, plans, models, projects for the line and approach lines; publications relating thereto. Group 3, alignments, geological sections, preliminary work, preparation of the plant at either side, water power canalization, the rock borers at work, examples of timbering and of steel frames, drainage, ventilation, refrigeration, types of masonry lining. Division 10 will be retrospective and historical. It will deal by illustrations, models and antiquities with the principal roads of the world, their bridges, viaducts and tunnels; with books, prints, saddlery, etc.; with the history of cars and carriages through the ages; with railways, cycling and automobilism, and aeronautics; with telegraph, demography and so on.

The exhibition will be open from April to November, 1906. Demands for space have to be received by the Exhibition Committee before May 31, 1905.—"Engineer," London.

THE GROMO-NEMBRO POWER TRANSMISSION LINE.

BY C. SMITH.

In the northern part of Italy, in the province of Lombardy, there has recently been installed and put in operation an extremely interesting power transmission line between the cities of Gromo and Nembro. The river Serio, a mountain stream rising in the Alps, furnishes 2,000 hp. at Gromo, and can furnish 2,000 hp. more at a point farther up the stream; of this amount only the 2,000 hp. at Gromo has been developed as yet.

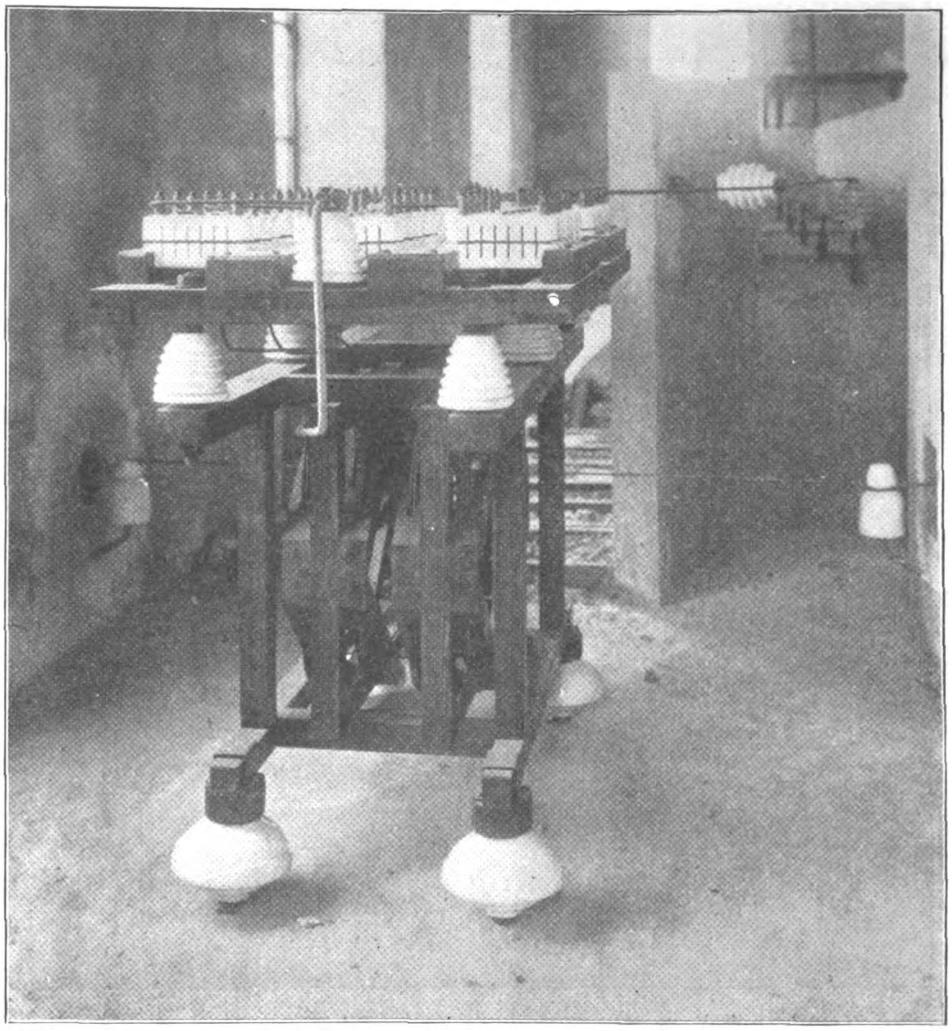

Fig. 1.—A Wurtz Lightning Arrester.

It was necessary to transmit this power to Nembro, a distance of 35 kilometers, where it would be used to drive the machinery at the cotton mills of Crespi & Co. of Milan. It was also essential that provision be made to transmit the remaining available power over a line on the same poles as the first line, which is the only one installed at present; this second line would be used to transmit the power to a greater distance. The loss in the line was to be very low, and the cost of installation was also to be reduced as much as possible.

At first it was decided to transmit the power by three-phase current at a pressure of 30,000 volts over three bare copper wires, each with a diameter of 6.5 mm., the drop on the line being approximately 4 per cent. But this plan presented, in this particular case, difficulties in the way of erecting the second line without interrupting the service of the first, and as the financial expenditure for two sets of poles would have been too great, it was imperative that the line should be designed from the start for a 4,000 hp. transmission. As the drop in the line was not to be more than 4 to 5 per cent., two plans were available, either to increase the diameter of the conductors, or to raise the tension on the line.

The second plan, however, was adopted as the additional cost was considerably less than in the case of the first plan, and it was decided to use a three-phase current at a tension of 40,000 volts for the transmission.

The power station at Gromo consists of three turbo alternator sets of 1,000 hp.

each, the third generating set being held in reserve in case of a breakdown. The alternators generate a three-phase current at a tension of 4,000 volts with a frequency of 50 periods per second. They are 12-pole machines and operate at a speed of 500 revolutions per minute, being connected to Escher-Wyss turbines.

Two exciters of 25 kilowatts each, direct coupled to turbines, are also installed and furnish a current of 217 amperes, with a pressure of 115 volts, the speed being 800 revolutions per minute. The alternators deliver the current at 4,000 volts to 850 kilowatt transformers, which raise the tension to 40,000 volts with a frequency of 50 periods per second and transmit it to the bus-bars. These oil-cooled transformers with water-cooling pipes use 18 liters of water per minute. The insulation between the primary and secondary windings has been tested at 67,000 volts.

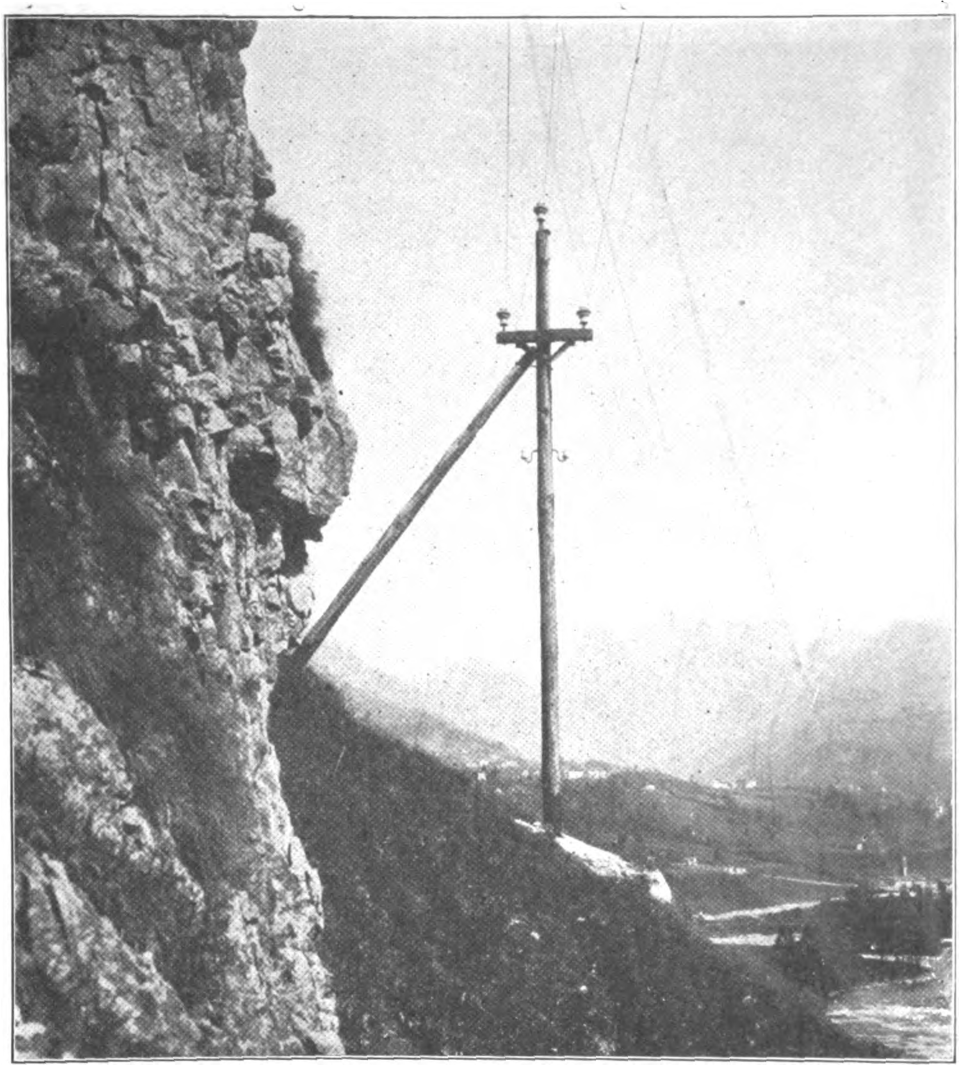

Fig. 2.—View of Power Transmission Line, Showing Use of Single Pole.

The switches as well as the transformers are located in a separate building which has three stories and a basement, the floor space being 10 by 7 meters. The basement is divided into two compartments; the first, which is 1.2 meters below the engine room floor, contains the regulating rheostats, and the second 2.7 below the level of the first floor, contains the transformers. The first floor also has two compartments, one for the switchboard and measuring instruments, the other for the high pressure automatic switches and the three transformers for the transmission line. The second floor contains the collecting bars and pressure transformers while the lightning arresters are on the third floor where the line leaves the building. These lightning arresters are of the Wurtz type, and insulated from the ground floor by porclain insulators. The care with which this is done can be seen from the illustration, Fig. 1.

The conductors, leaving the third floor through the window, are in thick glass tubes, and each wire is at least 250 mm. from all uninsulated bodies. The transmission line, which is about 32 kilometers in length, consists of three copper wires, 6.5 mm. in diameter, mounted on a new form of delta insulator designed especially for this installation. These insulators have stood a flash test of 80,000 volts.

The poles on which the insulators are mounted are 8 to 9 meters above the ground, and, as a rule, the lines are mounted on a single pole as seen in Fig. 2. Where there are sharp bends or long spans, two poles are used and the three insulators are fixed at the same height, the distance between them being 1,000 mm. while in the case of one pole, the insulators are 850 mm. apart. The poles are ordinarily 40 meters apart. The longest span is 120 meters and the largest angle is 145 degs. One and a half meters below the high tension line there are two wires, each of 3 mm. diameter, mounted on ordinary insulators, and forming the telephone line between the power house at Gromo and the sub-station at Nembro. The transmission line crosses a monophase 2,000 volt line at San Carlo, and at Albino it crosses another line and a canal.

The Nembro sub-station is a three-story building, the first and second floors being each divided into two compartments. The first floor contains the transformers, the disconnecting gear, and the secondary bus-bars as well as the current transformers. The high tension oil-switches and distributing panels are on the second floor, while the 38,000 volt bus-bars and lightning arresters are on the upper floor.

The current enters this sub-station at a tension of 38,000 volts. There is room for three 500 kilowatt three-phase transformers, but at the present time only two have been installed. They are of the same type as those at Gromo, only smaller, and reduce the tension from 38,000 volts to 500 volts. The insulation between their primary and secondary windings has been tested at 57,000 volts. The transformers have a length of 1,600 mm., a width of 1,155 mm., and a height of 2,005 mm. They require 13 liters of water per minute.

A three-pole switch mounted on poles outside the station, as seen in Fig. 3, allows the Nembro sub-station to be completely disconnected from the high tension transmission line. By means of three contacts fixed to the switch, the lines entering the station are short circuited and connected with the earth when the switch is open.

The current enters through the lightning arresters and passes to the high pressure bus-bars. It then passes through single-pole disconnectors and single-pole high tension automatic oil-switches to the transformers. The current from the secondary of the transformers passes through three-pole disconnectors and two current transformers. The transformers lead to the 500 volt distributing bus-bars.

This Gromo-Nembro power transmission line uses the highest voltage in

Europe up to the present time, and by its efficient operation during the past seven months, has shown without the possibility of a doubt the reliability and economy of high tension plants. The care with which the plant has been equipped by Brown, Boveri & Co., of Baden, Switzerland, who had this in charge, as well as the many protecting devices utilized, all combine to reduce the danger to life to a minimum.

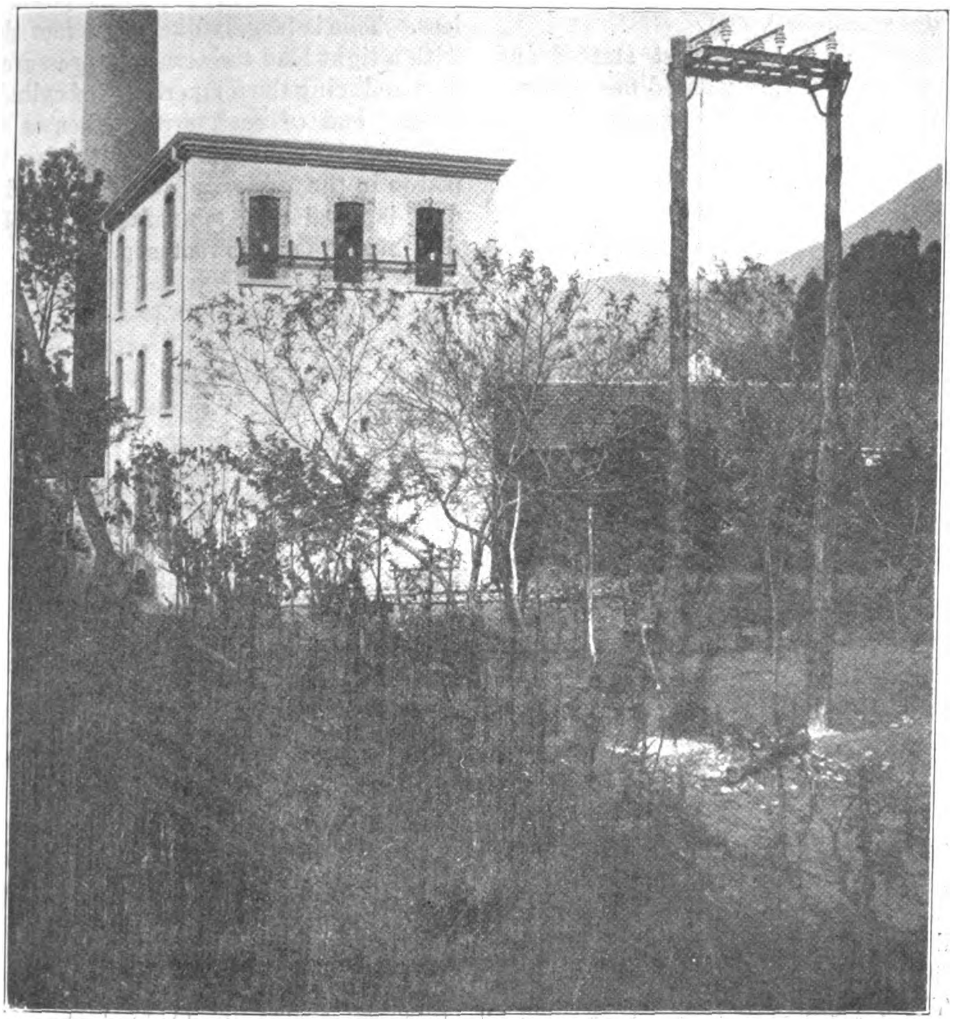

Fig. 3.—Power Transmission Line Entering the Nembro Sub-station.

* * *

PARALLEL RUNNING OF ALTERNATORS DRIVEN BY LARGE GAS ENGINES.*

BY E. KILBURN SCOTT.

It is surprising that there should be so much misunderstanding on this matter. The writer some time ago paid a visit to Germany and Belgium, where he had an opportunity of seeing the power stations connected with the Iron and Steel Works of the Phœnix Hutte (Nurnberg engines), Oberhausen Iron and Steel Works, near Dusseldorf (Korting engines), the Ilseder Iron Works, near Peine (Oechelhaeuser engines), and the Seraing Iron and Steel Works (Cockerill engines), besides several engine makers' works.

In these stations the engines varied from 500 to 1,500 hp., and, except in the case of the last, they were all driving three-phase alternators. They were supplied by blast furnace gas in all cases, and were of the single-crank type (except the Oechelhaeuser) working with two impulses per revolution.

The Oechelhaeuser engines at the Ilseder Works were twin engines, and, owing to the peculiar double-ended construction, had three cranks to each, or six in all, to drive one alternator, an unnecessary complication.

The writer can say absolutely that there is no difficulty whatever in running three-phase generators in parallel when driven by any of the engines named. At the Oberhausen Works, for example, there were two 1,200 hp. Korting engines driving Siemens' alternators and two 600 hp. Korting engines driving A.E.G. alternators. The machines ran absolutely in parallel; and further, they were so situated that it was impossible for the man on the switchboard to see all four engines when synchronizing.

In the case of the two largest units, by looking through the poles of the alternators one got the pretty effect of seeing them apparently standing still, or slightly swinging back and forwards, as one engine gained a little on the other; this movement, however, was very slight.

It may be stated as a fact that any single-crank large gas engine by a maker of repute, in which there are two impulses on the crank per revolution, and where sufficient fly-wheel weight is allowed either in the generator wheel, or better, in the generator wheel plus a fly-wheel, parallel running is quite easy.

Of course, there are points to be remembered; one is, that the "hit-and-miss" method of governing is absolutely no use for such work; it is entirely discredited on the Continent, and Cockerill's have superseded it even for blast furnace blowing engines, where good regulation is not important.

Another point is, that the higher the speed the better is the paralleling; and yet, on the other hand, there appears to be a consensus of opinion that it is well for the engine not to run above 100 revolutions per minute on account of wear and tear.

In the actual running of these blast furnace gas engines, the only thing that seems to cause trouble is the result of using water for cleaning the gas; in some cases a certain quantity of it is carried over into the cylinder and gets deposited on the sparking plugs which have to be then taken out and dried. This is, however, a matter which can be easily rectified.

Two of the A.E.G. alternators, coupled to Nurnberg engines, were of the very neat outer pole type which enables a very heavy fly-wheel rim to be provided on the alternator wheel so that no separate fly-wheel is necessary.

All the piston rods and pistons are cooled by water, also all the exhaust valves. A spray of water playing into the exhaust pipe effectually prevents any noise or chance of firing there.

The lubrication of the cylinders is usually effected by a thick block of unrefined petroleum oil called "Mazout." All the bearings and other working parts are, of course, lubricated with ordinary mineral oil.

The engines are always started by compressed air, at about 6 atmospheres for the small engines and 9 atmospheres for engines of 1,000 hp. and upwards. They start with absolute certainty, and, usually, the gas is turned on after a few revolutions only. The writer saw a 1,000 hp. engine get up to speed from rest in two minutes.

Regarding the number of men to run the engines taking all the stations together, this appeared to run out at about a man and a quarter per engine, including the foreman. There are no young electricians or pointer dodgers in these stations, just engine runners and a switchboard attendant; the foreman appears to look after the three-phase generators in his odd moments.

---

*From the "Electrical Review," London.

The work is practically identical with that of running a slow-running steam engine; indeed, some of the engines, the "Nurnberg" in particular, are surprisingly like steam engines, both in outline and detail. The spares carried are about the same as for steam engines.

The rapidity with which these engines are being adopted by the various iron and steel and other works on the Continent is very significant. Altogether the writer saw two dozen engines of over 500 hp. either running or nearing completion.

Fancy a power station, such as the one at the Ilseder Works, 240 feet long and 150 feet wide, in two spans, generating three-phase current at 10,000 volts, and transmitting it 10 miles by overhead wires to the rolling mills at Peine. I wonder what iron works in England would have the pluck to take on a job like that.

Why, the men who run these Continental works must be themselves electrical experts, for when they lay down a power station it is no half job but is undertaken with boldness and originality; no nibbling with direct current and petty little machines in a tin shed, but a tiptop first-class station worthy of a large concern.

Fifty years ago, the fathers of the men who run these works used to come to England to see engines and machinery; now the writer and many others are sent over there to report on what they are doing. And there is no mistake about it, the Germans, as a nation, are in training (in the deliberate way an athlete trains) for commercial supremacy. They have had their financial crisis and learned the lesson well.

Those amiable old folks whom one sees at Iron and Steel Institute meetings, etc., who are understood to control a fair part of what there is left of our iron and steel trade, will have to look out if they wish to retain the remainder.

Lord Kelvin's Latest Invention.

Lord Kelvin has perfected an invention which has already helped the London police considerably in their war upon the scorching motorist. It is an electrical machine for registering the time taken by a car in covering a certain distance.

PROVIDING FOR INCREASE OF POWER IN ISOLATED STATIONS.

ARTICLE II.

BY W. H. WAKEMAN.

Another plan for this purpose is shown in Fig. 2, where a high-speed engine is fitted with two flywheels and belted to two dynamos.

When the station is first started and only a few lights are wanted one dynamo can be used, then as the demand increases a second one can be put in service. When business still further improves another engine will be installed with one dynamo, and later on another dynamo will be added. This plan can be extended indefinitely.

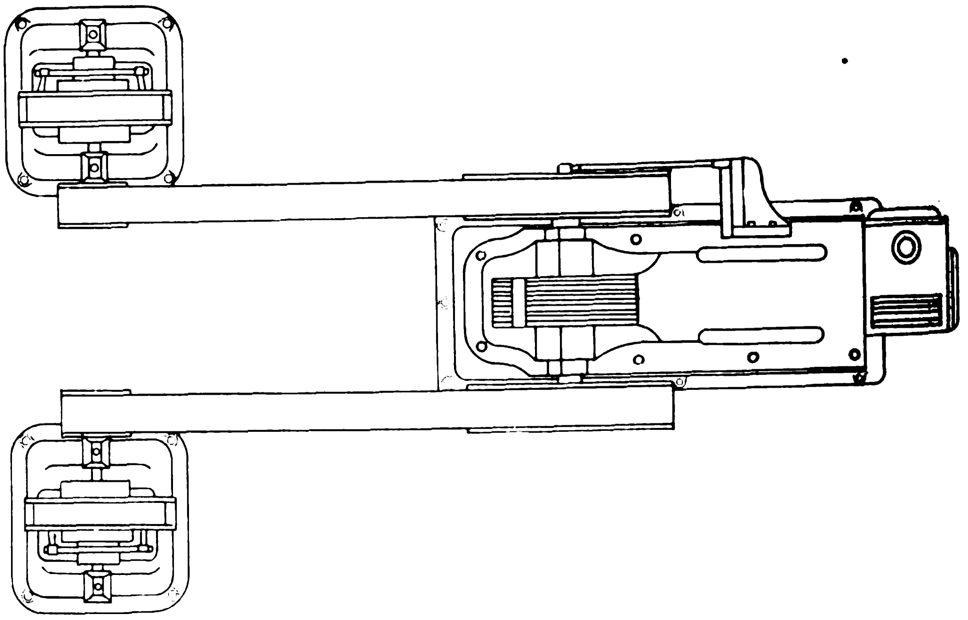

FIG. 2.

The objections to it are that when an engine that is calculated for two dynamos is driving only one it is running at a disadvantage, because it is underloaded. When I first heard or read the above statement it seemed as if it could not be true, for an engine runs so much better with a medium load, so far as "wear and tear" are concerned, that it appeared to be the best conditions for active service, but when we calculate the amount of coal required to produce one horse power for an hour, in a mill or shop, or per kilowatt hour in an electric station, under these conditions we find it more than good practice calls for.

Of course this condition of affairs cannot always be charged to one thing, as several unfavorable conditions may combine to produce the undesirable result, but where two engines are made alike, supplied with steam from the same boiler, and run the same in every way except that one of them is loaded so that its terminal pressure is about five pounds above atmospheric pressure, while in the other the expansion line crosses the atmospheric line at about one-half stroke, the former is far more economical than the latter.

More steam is required for a heavier load, but more power is developed than the direct increase of steam used calls for, therefore the amount per horse power is less. This is largely due to the fact that with a light load the terminal pressure is low, reducing the temperature of cylinder at the end of each stroke, then as the next charge of steam enters to drive the piston in the opposite direction its first duty is to raise the temperature of cylinder; but this means that some of the incoming steam is condensed in the process and is therefore a dead loss. As this is repeated twice for every revolution it seriously affects the consumption of steam.

With the direct connected generator, discussed in the previous article, the disadvantages of a high speed engine are found, but a low speed generator partially offsets these bad points. Where the belted generator, shown in Fig. 2, is used, a high speed engine is combined with a high speed generator, thus giving the bad points of both, so far as excessive friction resulting in rapid wear is concerned.

It is only fair to say, however, that these objections are almost eliminated in modern up-to-date machines, for ring and chain oilers have done much to reduce friction by providing copious and continuous lubrication, while engine builders have profited by past experience and given us engines that can be run continuously, or at least for several days, without shutting down. However, these high speed engines have not proved as economical as those of medium speed, especially after they have been used a few years.

One objection to the purchase and use of second-hand machinery is that although it may be in a fair state of preservation it does not always contain modern improvements, and lack of these features may have been one of the principal reasons for discarding it originally, therefore a practical man should decide on its merits before it is purchased.

One advantage of an outfit of this kind, composed of several small units, is that if a dynamo or an engine needs repairs, it does not disable the whole station as the other units can be run until repairs are completed.

On the other hand, it can be laid down as a general principle that the danger of accident increases directly with the number of parts in use. While this is true the objection as a whole is not so great as it was a few years ago for the same capacity of station, because improvements have made this class of machinery practically safe from sudden failure, provided it is well cared for.

It requires more men to operate a station containing high speed engines and belted generators than any other kind and when more engines are added, and the chief engineer calls for more help on this account, he should be supplied at once, for although one assistant engineer and one fireman can attend to the details of several engines and boilers it is not a good plan to overload the men any more than it is wise to overload the machinery.

CHIMNEYS.*

BY F. H. DAVIES.

As the efficient working of a natural-draught steam-raising plant is dependent greatly upon the manner in which its chimney has been designed, it follows that too much attention cannot be paid to the various minutiæ of the subject. Undoubtedly many steam installations are severely handicapped by unsuitable chimneys that, either through a false idea of economy or ignorance of the fundamental laws governing the generation of a draught, have been made too small, or are in some other way incapable of performing the necessary amount of duty. As the function of a chimney is two-fold, namely, the creation of a draught and the carrying off of the gaseous products of combustion, it must be considered under both heads, the first of which requires height and the second area. Several formulæ have been given for determining these two fundamental measurements, but as the problem is beset by many difficulties that vary considerably with local conditions, they are all of a somewhat empirical nature, being based upon observations of successful work.

The intensity of draught is dependent upon the difference in weight of the internal column of air and an imaginary external one of the same height and equal in diameter to the former at its smallest cross-section. The higher the chimney, therefore, the greater will be the force of its draught. This is measured in inches of water by the aid of a U tube, one end of which is left open to the atmosphere and the other connected to the interior of the chimney at its base. The difference in level of the water in these two legs shows the strength of the draught, which is found in practice to vary between ¼ inch, indicating a rather poor draught, up to 1 inch or over, equivalent to a very strong one. A usual formula for finding the theoretical draught in inches of water when the height is given is the following:

$$7.6\,H \times \frac{T_2 - T_1}{T_2 \times T_1};$$ H being the height in feet, T_1 the absolute temperature of the atmosphere, and T_2 the absolute temperature of the chimney gases. The result will be the required figure in inches of water. In designing a chimney it is usual to fix the height more or less arbitrarily, basing it upon previous practice, and with this quantity known it becomes easy to calculate the area from one of the usual formulæ. That due to Kent is very commonly used and is as follows:

$$A = \frac{.06\,F}{\sqrt{H}};$$ where A = actual area in square feet, H = height in feet, F = pounds of coal per hour that will be consumed. From this it is obvious that the quality of coal is a factor to be taken into consideration, as the value of F will vary with it for any given load; hence, for safety, a chimney should be designed to deal with the worst coal that is ever likely to be burnt in the furnaces. There must be, of course, a certain amount of friction between the escaping gases and the lining of the chimney, and this has been estimated to result in a layer of gas approximately 2 inches thick adhering to the sides, and therefore appreciably reducing the effective area to a value below that of the actual area. The formula $E\,A = A - 0.6\sqrt{A}$ is used for determining the effective area, A, the actual area in square feet having been found as above. Another formula is that due to Christie. It is handy for determining the maximum horse power of plant that any given chimney is capable of providing draught for, and is based upon the assumption that 4 pounds of coal are consumed per horse power hour. Using the same notation as previously it is as follows: $H.P = 3.24\,A\sqrt{H}$.

It is common knowledge that a draught that will suffice for the proper combustion of one kind of coal may be quite inadequate for another; hence it follows that the sort of coal most likely to be used enters into the question of height as well as that of area. Good bituminous coal requires the least draught, and therefore the lowest chimney, and small anthracite may be taken as the other extreme. Nothing under 70 feet in height is of much value with natural draught, even for a small plant burning the best bituminous coal, and it is better by far to err upon the side of unnecessary height as this allows more scope for forcing and in the variety of coal that may be used.

In the actual shape and building details of the chimney there is much to be considered. The nature of the materials of which it is to be composed, either brickwork or steel, its foundations, shape, stability as regards wind pressure, and other details, all of great interest and importance, enter into the question. In this country the brick chimney is by far the commonest, but in America both the stayed and self-supporting steel type are very much in vogue. They are each cheaper than a brick chimney in capital cost but having to be repainted once a year to save deterioration through corrosion add an amount to maintenance that in small plants is somewhat heavy and disproportionate. A well built brick chimney requires no repairs for years, and then only such as are of a trifling nature; consequently, it is preferred by many despite its capital cost and the fact that the steel shaft is slightly more efficient, owing to the entire absence of the leakage that is always going on through the pores of bricks and mortar. If, however, considerations of capital cost must outweigh those of revenue, the firebrick-lined steel chimney is the thing; the unlined variety need not be considered, as owing to radiation it is inefficient in the extreme.

There are two kinds of these stacks, self-supporting and stayed; the former is preferable from the point of view of appearance, and is, indeed, the only type that can be used for large work owing to staying difficulties, but it costs rather more than the latter variety, having to be much more substantial in every way. The stayed form is generally used in small power plants, being very cheap as compared with a brick shaft, and giving equally as good results if brick lined. It is built of iron or steel in cylindrical sections, which are usually lapped and riveted, although sometimes butted with a covering piece riveted on. The foot of the chimney is bolted to a heavy ring placed upon a substantial brick base, generally as high as the building, and this forms the first stage of the shaft. Wire guy ropes, usually four in number, are taken off some three-quarters of the way up by means of a ring provided with hooks or suitable attachments and fastened through turnbuckles to bolts sunk well into the building structure.

---

*From the "Electrical Engineer," London.

The design of a brick chimney is a much more complicated matter than that of its steel prototype, for here various external and internal shapes are possible, whereas the cylindrical is the only form that the latter can be adapted to. Although, perhaps, the hexagonal chimney presents the most pleasing appearance, for a given area it has a smaller capacity than a circular one, and in addition exposes more surface to the overturning power of the wind. It is not, however, so bad in either of these respects as the square chimney, the internal corners of which introduce considerable resistance to the outflowing gases, and the flat external faces a comparatively large area to be acted on by the wind. This overturning force is naturally one that has to be taken into full consideration, and with a given wind pressure it will, of course, vary with the shape of the shaft, whether round, hexagonal or square. For this reason a certain relation must exist between the height, width, shape and weight of a chimney; and given these three former the latter may be found by the following formula: Where C = a constant for the various shapes—28 in the case of round, 35 octagonal, and 56 for a square chimney—H = height in feet, D = average diameter, B = breadth of base and W = weight in pounds,

$$W = C\frac{D\,H^2}{B}.$$

The proper proportioning of the foundations of a shaft is of the greatest importance, as its future welfare largely depends upon this. All proceedings must be based upon a thorough knowledge of the bearing power of the soil, which varies much with its nature. Usual practice defines the safe weight per square foot at one ton for soft clay and two tons for stiff clay or lightly packed sand; but if the soil is at all marshy efficient piling must be resorted to.

The external diameter at the base of a brick chimney should not be less than one-tenth of its height and the batter or taper usually allowed is from $\frac{1}{16}$ inch to ¼ inch on each side. The internal diameter should not vary appreciably from base to top, and the firebrick lining that is always provided is built up straight with no batter, thus leaving an air space between it and the outside wall. This lining generally extends from two-thirds to three-quarters of the total height, although in cases it is carried to the top. In the event of two flues entering a chimney at different sides, it is always desirable to build a feather or mid-wall between them to about a quarter of the height so that the gases from each have a separate path to start with. If this is not done, they are liable to baffle each other as they emerge from the flues and this may cause a considerable diminution in the efficiency of the chimney.

The usual thicknesses for the outer shell of a brick shaft are as follows: Shaft up to 3 feet internal diameter at top—4 inches for first 10 feet downwards, after this an increase of 4 inches at every 25 feet; shaft over 3 feet and not more than 5 feet internal diameter at top—8 inches to start with, increasing by 4 inches for every 25 feet downwards; shaft over 5 feet internal diameter at top—12 inches to start with, and same increase. The inner firebrick lining may be 4 inches thick for the first 20 feet or so, increasing by 4 inches at every 10 feet downwards.

ELECTRICITY LEAFLETS.

BY NEWTON HARRISON, E. E.

ELECTRIC RAILWAYS.

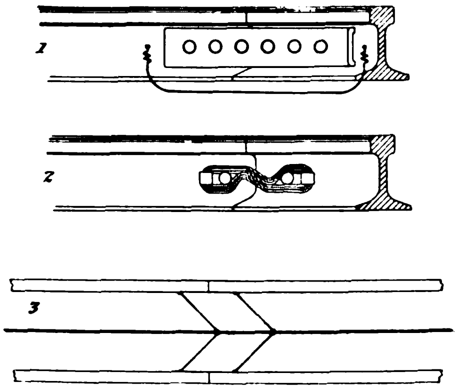
The Overhead Trolley.—The cars in this system are fed with current from the trolley wire and tracks. The trolley or pole ends in a trolley wheel which presses against the trolley wire and completes the circuit. The trolley wire of No. 0 size Brown & Sharp gauge, is supported above the track by means of wires and poles which hold it over the middle of the track. The rails are electrically continuous by means of copper bonds which join adjacent ends. Both trolley wire and tracks are reinforced at intervals by means of additional supply wires called feeders. The current enters at the trolley wheel, passes down the trolley and enters the motors via the controller. The name controller is obviously the best that could be chosen, because by means of this device the current supply is controlled and the speed and power of the motors properly regulated. The pressure employed for trolley car service is 500 volts. It is not supposed to be of sufficient strength to destroy human life, although many instances have been recorded of such unfortunate circumstances.

The Trolley Wire.—The trolley wire is made of hard drawn copper and the wires stretched across the track from pole to pole are called *span* wires. The trolley wire is also supported from brackets attached to or forming part of the posts, which are partly or wholly of metal. The construction in this respect must be such that the trolley wire, though firmly held is still elastic, otherwise the pressure of innumerable trolley poles would eventually bend it out of shape. At various points along the trolley line, where the traffic is heaviest, the wire is connected to feeders. It is also connected to feeders at those portions of the system furthest removed from the power house. These more or less distant points do not suffer so much from heavy traffic as from the effects of heavy drop. As each car takes from 50 to 150 amperes, depending upon its load and speed, and the resistance of a few miles of wire, however large in size, is quite an item, it becomes evident that the degree of drop, the product of this resistance and the current of whatever cars may be taking energy at this comparatively distant point, will be quite a percentage of the total pressure. This would cause the cars to run slow for two reasons—first, the pressure is low, and, second, the current is less because the pressure is low. The series motor is controlled, as regards its pull and speed, by just such conditions as those described, which can be incorporated into the general statement that where series motors are concerned the following is true:

Rules for Series Motors.—1. In a series motor the pull increases if the current increases and the pull decreases if the current decreases. 2. In a series motor the speed increases if the volts at its armature terminals increase, and its speed decreases if the volts at its armature terminals decrease.

Continuing the argument with respect to drop in the trolley wire, suppose six miles of this wire are considered of an average resistance of ½ an ohm to the mile, this would give a total resistance of 3 ohms. If one or two cars are consuming about 150 amperes at this point, the drop in the line before the energy is consumed equals 3 × 150 = 450 volts. It is easy to realize how completely a trolley system would fail under these conditions. In fact, a dozen cars would be the means of causing so complete a drop that practically no available energy would reach this distant point. It would be no exaggeration of the truth to state that in a large cosmopolis a trolley system represents an impossibility unless hundreds of tons of copper in the capacity of feeders are employed to carry current all along its circuit. The trolley wire, therefore, is not actually carrying the electrical energy, but its feeders. The problem is one of reducing drop to a certain practical minimum, which involves one of the heaviest investments on the part of the company. If, for instance, it takes 1,000 pounds of copper feeders to reduce the drop 1 per cent., it follows as a mathematical certainty that it will take 2,000, 3,000, 4,000 or 5,000 pounds of feeders to reduce the drop 2, 3, 4 or 5 per cent.

Bonding.—The reasoning which applies to the trolley wire of a street railway system also applies to a large extent to the tracks or rails as well. The difficulties here were originally found in the bonding of the rails. All that is required in ordinary railroad practice is to firmly secure the rails together mechanically by means of fish plates. A method of joining track lengths together such as this is mechanically good but electrically bad. Rust soon prevents a good contact from existing and the result is a high resistance joint. A series of such defects would rapidly use up the pressure when a heavy current is required, consequently an electrical contact is secured by means of bonding. To bond the rails means to establish connection between them by means of a heavy flexible copper wire or cable. The ends of this wire or stranded cable are riveted into the rail, the rivet and joint being proportioned with respect to the current which passes. It is here that the weak spot in trolley systems manifests itself, as subsequent facts will show. The rails when bonded represent two long lines of electrical conductors upon which the wheels turn and also establish the circuit through the motors from the overhead trolley wire.



1—Fishplate and bond wire. 2—Bond wire. 3—Bonding to a middle wire.

Another method of bonding is to run a wire or cable along the middle of the track and attach wires to it from the rails. In other instances the wire laid between the tracks zigzags from rail length to rail length and establishes connection. Whatever the method may be the most ideal is that employed by welding the tracks into one continuous track. Track or rail welding is the most satisfactory in the end for all the reasons which appeal to the electrical expert. The other methods though good are subject to conditions which eventually destroy their integrity. If the resistance at any one bonding averages up $\frac{1}{100}$ of an ohm, then 1,000 bonds give a resistance of 10 ohms. As this is duplicated on the other track as well, and as this track is in multiple, the net resistance would be 5 ohms. Reducing the average resistance of any one bond will still give for the aggregate resistance a very high figure. The difficulty lies in the fact that bonding steadily depreciates in quality, due to the saline matter in the streets and the by-products of the earth itself. Iron and copper form a voltaic couple, which helps to increase the bad effects of general corrosion due to ordinary causes. A current of 1,000 amperes given up by the line at any particular spot, due to a block of cars causing the almost simultaneous starting of a group of them, would cause a very heavy line drop unless the resistance is exceedingly low. It is readily seen that a resistance of $\frac{1}{10}$ of an ohm means a drop of $\frac{1}{10} \times 1{,}000 = 100$ volts. On a 500 volt circuit this means a waste of 20 per cent. of the total energy.

Electrolysis and Bad Bonding.—The energy which is not conducted through the tracks will pass through all the available gas and water pipes in the neighborhood. The statement found in Ohm's law, that the current is directly proportional to the E.M.F. and inversely proportional to the resistance, explains why the current will leak away from the tracks whenever the bonding is bad and take into its circuit water and gas mains. In passing from one to the other of these the moist earth acts as the electrolyte and the pipes as the electrodes of an electrolytic cell. The metal is carried from point to point from the outer walls of the pipes as shown by the deep pitting which results. Thus the effects of poor bonding are manifested in two ways:

First—Loss of power.

Second—Electrolysis.

In very wet weather these results are exaggerated and the general leakage throughout the systems rises to very high figures. But the two most readily controlled losses are those found in a poorly fed trolley wire and a badly bonded track.

The Controller.—The controller has been simplified in the last 10 years until it has reached a point which approximates perfection. The car motors are designed with reference to the speed of the car, its weight and acceleration; the controller is designed with reference to the starting and stopping of the car, the current consumption and the control of the circuits. If two series motors are considered, it is readily realized that the sudden throwing on of the power would result in probable accidents to those on board the car. The suddenness with which the car will start is largely dependent upon the current passing through the motors. If they are at rest and it is fully turned on, aside from the action of automatic circuit breakers, it is evident that with no back electromotive force, an enormous current would tend to flow. This would start the car with a jerk and, of course, would not be tolerated in any case. The current governs the pull of the motor, therefore to avoid too rapid a development of torque the current must be introduced to the motors through the medium of resistance. A variety of connections must be made and unmade, so as to rapidly bring the motors from a condition of rest to one of rapid motion. If in the first process a resistance is interposed, at the last process of all both motors are in multiple across the circuit. Between these two extremes of a small starting current and direct and uncontrolled consumption from the circuit exists a series of important combinations as follows:

MOTORS IN SERIES.

1—Motors in series with a resistance and with each other.

2—Motors in series with less resistance and with each other.

3—Motors in series with still less resistance and with each other.

4—Motors in series with each other (no resistance in).

5—Motors in series with each other and fields shunted.

MOTORS IN PARALLEL.

6—Motors in parallel with each other and resistance in.

7—Motors in parallel with each other and less resistance in.

8—Motors in parallel with each other and still less resistance in.

9—Motors in parallel with each other and no resistance in and fields shunted.

These combinations are the ones affected by the General Electric K2 street car controller. As can be seen from the description given in conjunction with the combinations it is of the series parallel type. There are really a series of combinations produced between 5 and 6 which are called intermediate connections These are the connections which throw the motors from series into parallel. The equivalent of these combinations are given in diagrammatic form in the sketch and represent the foundation on which is built the controller largely employed in Manhattan Borough, Greater New York, for street car, elevated and subway service. In looking over the series of diagrams given it will be noted that combinations 1, 2, 3, 6 and 7 call for the use of the rheostat, while combinations 4, 5, 8 and 9 do not; therefore the former must never be used for any great length of time to run the car, while the latter are allowable. It is obviously wasteful to run a car with resistance in series, and this rule applies also to the intermediate positions lying between 5 and 6, which are cases where the rheostat is in circuit. The diagram showing the general motor connections, including the controller contacts, shows the position of the various switches and cut-outs. The development of the reversing switch is also shown, the movement of which to the right or left reverses the direction of rotation of the motors and hence of the car itself. The general principle underlying these connections is that of gradually increasing the volume of current passing through the motors. From position No. 1 to No. 9 this idea is systematically carried out from having fields, armatures and resistances in series in the first case to having fields and armatures in parallel with no resistance in the last case. Thus, the engineering requirements, which are nothing more than the scientific requirements, are satisfied. The conditions in general being these, that

First—The pressure along the system both in the tracks and trolley wire is sustained by means of feeders.

Second—The current is introduced in ever-increasing value by means of the controller.

With a uniform pressure along the line the speed will not drop, with a uniform type of motor and with a scientifically constructed controller the ultimate motor torque will always be at a high figure, these two securing the valued features of electric street railways, good speed all along the line and comfortable and economical acceleration.

Lecture to Engineering Students.

On Friday afternoon, March 17, Mr. Chas. E. Downton of Pittsburg gave a very interesting lecture before the engineering students of the University of Minnesota, describing the works of the Westinghouse Electric & Manufacturing Company. With the aid of a moving picture machine, he took his audience from the union depot in Pittsburg along the Pennsylvania Railway past the various factories of the Westinghouse companies, thence through several shops of the electric factory, showing the numerous steps in the construction and testing of electrical machinery. Of particular interest were several series of views showing heavy work in progress in the forge shop and foundry. The audience was much impressed by the magnitude of the works and by the long lines of employes leaving the factory and taking the trains, some 12,000 employes being engaged.

HIGH PRESSURE LINE CONSTRUCTION FOR ALTERNATING CURRENT RAILWAYS.

BY THEODORE VARNEY.

Abstract.

A paper was read at the 195th meeting of the American Institute of Electrical Engineers, March 24, treating of the above subject with particular reference to the details of construction involved. The writer, Mr. Varney, shows how advantageous the alternating current becomes in street railway service by the possibilities of high pressure, provided a good alternating current motor is at hand. The overhead trolley is the only means of using pressures of 3,000, 6,000 or 10,000 volts in contrast with the third rail for the obvious reasons of insulation and safety. The author advocates a system of substantial construction in which the use of thousands of volts will not militate against the longevity or durability of the installation. The present steam roads, if electrified, would call for the most solid and substantial class of work to insure their permanent operation. The lighter interurban roads, however, are not bound down to such emphasized substantiality. The cost of equipment in this case would not be very heavy as compared with the former. The author then enters into a description of the bracket arm, cross span and bridge construction for the high-tension purposes in view.

The important feature of the bracket arm construction is the insulator of corrugated porcelain, cemented to a malleable iron sleeve which in turn is slipped over the bracket arm and held by clamps and set screws. This insulator has a groove at its center fitted with an iron collar. The iron collar has an eye to which the messenger wire or steel supporting cable is attached by means of a hook. From the messenger wire the trolley wire is permanently supported by means of clips or hangers. The author states that unless the trolley wire as a whole is so supported that vibration to any considerable extent is checked waves or ripples will pass through it, the effect of which is to lift the wire from the trolley as it passes and thus cause arcing. This is particularly true in the case of a too rigidly supported line. The trolley line is supported at intervals of 10 feet, thus preventing the broken ends of the wire, if it should break, from touching the ground.

The hanger employed, according to the author, consisted of a galvanized malleable iron casting made in ten lengths. It was fitted with a bolted clamp to take the messenger cable and was secured to the trolley with screws. The effect of temperature upon the spans was recorded for a series of cases where the spans were 96 feet and 120 feet and the data obtained showed a change in height of about ½ and 2 inches respectively, at about 37 degs. F.

The care and thought betrayed by the author in his consideration of the requirements of substantial support and insulation to the trolley wire, are evidences of the highest appreciation of the serious nature of the problem involved.

For instance, he states that with a (0000) grooved trolley wire and hangers spaced 10 feet, the average load per foot on each cable is 1.43 lbs., and with a vertical sag of 2.7 feet, the tension is 6,000 pounds. In rough weather climatic conditions, such as wind and sleet, will raise this tension to double this figure. The breaking strain of the cables employed was above 40,000 pounds, thus preserving a large enough safety factor as far as strength is concerned, to meet all ordinary emergencies. The author states as follows: Regarding the efficiency of the insulation employed, it may be stated that under the snow-clad conditions (as described), the 2,500 feet of iron bridge work and five miles of single catenary construction showed under test a leakage of one ampere at 6,000 volts.

In conclusion the author states how the attempt has been made, which seems so far to be successful, to develop a system of overhead conductors for moderate and heavy traction service, which would approach the reliability and permanency of steam railroad equipments. In Indiana 40 miles of road have been in successful running order since the beginning of the year at a working pressure of 3,300 volts. About 60 more miles of road will be completed in the near future. The author speaks of the air-operated sliding bow trolley, a type of which he shows insulated, to stand a pressure of 6,000 volts.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED MARCH 21, 1905.

Electric Railways and Appliances.

785,183. Overhead Trolley. Frank J. Prue, Woonsocket, R. I. Filed Nov. 7, 1904.

785,293. Electric Tramway. Alfredo Diatto, Turin, Italy. Filed Sept. 30, 1902.

785,294. Railway-Signal. Philip S. Dorion, Troy, N. Y., assignor of one-half to Charles B. McMurray, same place. Filed April 23, 1904.

785,315. Electric Railway. Timothy Mahoney, San Francisco, Cal. Filed Dec. 1, 1903.

785,372. Trolley-Head. Eugene J. Parker and Louis N. Colwell, Providence, R. I. Filed April 27, 1904.

785,482. Fender. Raffaela D'Oronzio, New York City. Filed Dec. 7, 1904.

785,490. Trolley Mail-Box. Wallie Hills, Kansas City, Kan. Filed Nov. 29, 1904.

785,598. Trolley. Clemens Dillhoff and Joseph Hastreiter, Morgantown, W. Va. Filed Dec. 13, 1904.

785,657. Insulated Step-Joint. Bancroft G. Braine, New York City, assignor to the Continuous Rail Joint Company of America. Filed Feb. 10, 1904.

Electric Lights and Appliances.

785,481. Portable Electric Lamp. Henry D'Olier, Jr., Philadelphia, Pa. Filed Sept. 30, 1904.

785,483. Incandescent-Lamp Holder. Jonas Feighner, Shelby, O. Filed Sept. 23, 1904.

785,516. Electric-Arc Lamp. Charles Oliver, Woolwich, Eng. Filed Feb. 29, 1904.

785,626. Socket for Electric Lamps. James A. Mebane, South Boston, Va. Filed April 30, 1904.

Electrical Machinery and Apparatus

785,306. Electrical Fuse-Box. Gilbert W. Goodridge, Bridgeport, Conn., assignor to the Bryant Electric Company, same place. Filed June 16, 1904.

785,379. Electric Welding Machine. Adolph F. Rietzel, Lynn, Mass., assignor to the Thomson Electric Welding Company, same place. Filed Nov. 16, 1903.

785,405. Electrical Switch. Robert G. Clark, Brooklyn, N. Y., assignor of one-half to U. L. Laughlin, Schenectady, N. Y. Filed April 16 1904.

785,419. Electric Switch. David E. Gray, New York City. Filed June 6, 1904.

785,487. Regulator for Alternating Currents. Edward L. Haney, Nashville, Tenn. Filed Sept. 3, 1904.

785,499. Electric Generator. William Kaisling, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Manufacturing Company. Filed July 20, 1903.

785,532-533. Synchronous Motor and Two-Speed Winding for Three-phase Motors. Ernst F. W. Alexanderson, Schenectady, N. Y., assignor to the General Electric Company. Filed Aug. 12 and 13, 1904.

Telephones and Telephone Apparatus.

785,103. Telephone Selecting Mechanism. John P. Jackson, Orleans, Ind. Filed June 30 1903.

785,673-674. Telephone System. Isidor Kitsee, Philadelphia, Pa. Original application filed Feb. 24, 1902. Divided and last application filed Aug. 4, 1902.

Miscellaneous.

785,076. Printing-Telegraph. John C. Barclay, New York City. Filed March 1, 1904.

785,276. System of Wireless Telegraphy with Tuned Microphone-Receivers. Adolf Slaby, Charlottenburg, and Georg G. Arco, Berlin, Germany. Filed Sept. 27, 1901.

785,297. Gas-Separator for Storage Batteries. Thomas A. Edison, Orange, N. J., assignor to the Edison Storage Battery Company, same place. Filed Aug. 16, 1904.

785,316-317. Production of Sound-Records and Sound-Record. George A. Manwaring, Bayonne, and Victor H. Emerson, Newark, N. J., Eugene E. Norton, Nichols, Conn., and Frank L. Capps, London Eng., assignors to the American Graphophone Company, Bridgeport, Conn. Original application filed April 14, 1904. Divided and last application filed Oct. 4, 1904.

785,338. Means for Progressively Establishing and Dissolving Spheres of Magnetic Influence. Guion Thompson ond Huntington W. Merchant, New York City, assignors to the Thompson Safety Appliance Company, Jersey City, N. J. Filed Aug. 17, 1903.

785,366. Vacuum-Electrode. Robert Machlett, New York City. Filed Dec. 1, 1904.

785,403. System for the Rectification of Alternating Currents. Charles F. Burgess, Madison, Wis. Filed Aug. 15, 1903.

785,445. Bridging Circuits for Electric Circuits. Guion Thompson, Duluth, Minn., assignor to the Thompson Safety Appliance Company. Filed Aug. 2, 1902.

785,446. Electromagnetic Block System. Guion Thompson, Duluth, Minn., assignor to the Thompson Safety Appliance Company. Filed May 16, 1901.

THE TELEPHONE WORLD.

Cut in Telephone Rates.

U. N. Bethel, first vice-president and general manager. of the New York Telephone Company, has informed the Merchants' Association that after May 1 telephone rates to subscribers are to be reduced.

All direct line business subscribers will be charged at the new rate, regardless of the rate named in existing contracts. The new rate will be $60 for 600 messages instead of $75; $87 for 1,200 messages instead of $111; $111 for 1,800 messages instead of $141. The rates on 2,400 and more messages will be correspondingly reduced until the rate on 4,500 messages will be cut from $228 to $204 a year.

After June 1 this new schedule of rates from Manhattan and the Bronx will be adopted:

	From Manhattan.		From the Bronx.	
	Subscribers.	Pay Station.	Subscribers.	Pay Station.
Astoria	10	15	15	20
Barren Island	20	25	20	25
Bath Beach	15	20	20	25
The Bronx	10	15	—	—
Brooklyn	10	15	15	20
Coney Is'nd, Sheepshead Bay	15	20	20	25
Far Rockaway, Lawrence, Hammels	20	25	20	25
Flushing	15	20	15	20
Jamaica	15	20	15	20
Manhattan	—	—	10	15
New Dorp	15	20	20	25
Newtown	10	15	15	20
Queens	15	20	15	20
Richmond Hill	15	20	15	20
Tompkinsville, West New Brighton	15	20	20	25
Tottenville	20	25	20	25

A new schedule of rates for Brooklyn, places the toll for subscribers at $54 for a direct line, 600 calls, where it was formerly $66 for 700 calls, in the business districts, and $60 a year for a direct residence line instead of $75 as heretofore. In the Bath Beach and Coney Island districts there will be a reduction to $24 a year for party lines in private residences.

As a result of a meeting of a number of business men of Garretson, S. D., and farmers residing in that vicinity, the Palisade Telephone Company was organized. The following officers were elected: President, Adolf Koch; vice-president. A. O. Lerdahl; secretary, John Engebretson; treasurer, F. E. Locke. The line of the company will extend to a large number of farms in that part of the State, and will be connected with the local telephone systems of both Garretson and Sherman.

Capitalists and others whose business interests will be promoted, are endeavoring to form a company to construct a telephone line from Magnolia to Tylertown, Miss. The distance is 21 miles, and telephone interests would greatly facilitate the business interests of both places.

Moult Mount, manager of the Farmers' Telephone Company at Hopedale, Ill., will soon commence setting poles and stretching cables in the streets of Mackinaw, Ill.

Independents Preparing for Important Conference.

The coming convention of the Ohio Independent Telephone Association, to be held at the Hartman Hotel, Columbus, March 30, promises to be one of the best attended and most important conferences of Independent telephone men that has been held since the organization was formed.

Frank L. Beam, president of the association, has received assurances that each of the nine sub-district organizations will send its full quota of delegates, or one for each 1,000 telephones or less. He is led to believe that there will be at least 250 representatives of the Independent companies in attendance.

The officers of the association are: Frank L. Beam, president, Columbus; E. E. Knox, secretary, Portsmouth; Ralph Reamer, treasurer and assistant secretary, Columbus; executive committee: Ed. L. Barber, Toledo; Cyrus Huling, Columbus; J. B. Hoge, Cleveland, and Dwight E. Sapp, Mt. Vernon.

Bill to Tax Telephones.

The Francisco bill introduced in the New York Assembly proposes a tax of $5 per year to be paid by the telephone companies for each telephone operated, half the sum to go to the State and half to the town or city where such instruments are in operation.

News from Faribault, Minn., states that the Rice County Rural Telephone Company has filed articles of incorporation. Its capital stock is $100,000, divided into 10,000 shares, 5,000 preferred, and 5,000 common. The officers are: A. G. Chase, president. Isabella G. Chase, vice-president; W. T. Mollison, secretary and treasurer. The company will begin at once to install the plant.

The work of organizing a company for the construction of a telephone system between Toronto, Brandt and Astoria, S. D., is progressing. At a recent meeting a committee was appointed to prepare the articles of incorporation. Stock to the amount of several thousand dollars has been subscribed for.

Telephone facilities are being extended in the farming section surrounding Bennington, Vt. It is expected a line of several miles in length will shortly be constructed. The number of telephones in use in Bennington has now reached about 300.

D. E. & J. O. Kelley, merchants of Jeff, Ala., are completing a long-distance telephone system from Huntsville to that place. The new line will serve from 30 to 50 patrons.

The Fosterburg and Upper Alton Main Line Telephone & Telegraph Company, of Upper Alton, Ill., has changed its name to the Star Telephone & Telegraph Company.

The MacDougall, N. Y., Telephone Company has completed the erection of poles for its line from Geneva nearly to Kendaia.

The Boomerline Mutual Telephone Company, of Ottawa, O., has lately been incorporated by H. J. Hermiller and others.

Automatic 'Phones for Naval Station.

The contract has just been awarded for a private telephone system for the New Orleans, La., Naval Station, which will be of the automatic variety. It is expected that the system will be ready for operation in about three months.

The automatic exchange of the system will be connected with 25 telephones at the outset, but will provide for an ultimate capacity of 500 telephones. The local company will do the general wiring for the system, and the Automatic Telephone Company, of Chicago, will install the other equipment of the central exchange and the telephones.

The policy of the United States Government has of late appeared to be to install the automatic telephone service for its exchanges. The specifications for the installation at the New Orleans Naval Station called for automatic telephones manufactured under the Strowger patents by the Automatic Telephone Company, of Chicago, and consequently shut out all other telephone systems from the competition.

The Putnam, Conn., Business Men's Association had a large and enthusiastic meeting recently to consider the telephone situation. A committee of three, Col. G. D. Bates, G. E. Shaw and William H. Hammond, was appointed to look after pending legislation. Resolutions were passed calling attention to the condition of telephone service in that vicinity, and the desirability of legislation to remove restraint on competition.

Manager Domser, of the Black River Telephone Company, of Boonville, N. Y., lately sent out notices to the effect that after the first of April the price of telephones would be raised so that each 'phone would bring $12.50. This will have the effect of reducing a number of 'phones about that village.

To telephone from any one of its 54 mines direct to the company's headquarters at Pottsville, Pa., is the feat the Reading Company expects shortly to accomplish. That company is trying a new style of telephone in its inside mine workings, with this end in view, to expedite and safeguard the business.

The Farmers' Mutual Telephone Companies at Carroll, Henry, Ogle, Whiteside and Bureau Counties, Ill., representing 30,000 telephones, organized lately for protection against the old companies, especially the Bell.

A bill has been introduced in the Connecticut Legislature for the incorporation of the New York Independent Telephone Company.

Telephone Incorporations.

The Brainerd Telephone Exchange Company, Brainerd, Minn. Capital stock, $50,000. Incorporators: C. A. Waker, Warner Hemstead, F. H. Cruenbagen, H. P. Dunn, Mons Mahlam and H. D. Treglawny.

The Dunkard Valley Telephone Company, Garrison, Pa. Capital stock, $5,000.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Ackerman, Miss.—It is reported that T. F. McGee contemplates installing an electric light plant.

Ackley, Ia.—Improvements to the extent of $3,000 will be made to the heating and electric light plant here, operated by the Smith Brothers.

Amite, La.—The erection of another electric light and power plant here is in progress. The promoters of the new enterprise are H. C. Hall, of Amite; Hyman C. Reed, of New Orleans, and others. The new plant purposes to furnish light for Roseland and Independence.

Ashland, Va.—Frank J. Gould and others, have applied for a franchise to construct and operate an electric light and power plant.

Athens, Tenn.—The Athens electric light plant has been purchased by Long Bros.

Breese, Ill.—At the coming village election the question of establishing an electric light plant will be submitted to the voters.

Cherry Tree, Pa.—The Cherry Tree Electric Light, Heat & Power Company, with a capital of $5,000, has been incorporated by W. T. Mahaffey, R. E. Pitcairn, B. P. Kinports, C. V. Cameron and others.

Dayton, O.—The Montgomery County Electric Light Company, which has been incorporated by Robert R. Nevin, R. R. Knowles, Fred A. Funkhouser, Fred G. Withoft and William R. Craven, will conduct a business along domestic lines.

Dresden, Tenn.—This city contemplates issuing $10,000 of bonds for the construction of an electric light plant and waterworks.

Eureka, Ill.—W. J. Whetzel has been granted a franchise for an electric light plant in this city.

Fairview, Utah.—Incorporation papers for the Fairview Electric Light & Power Company have been placed on record by the Secretary of State. Its capital stock is $15,000, and officers: President, Peter Olsen; secretary and treasurer, Peter Sundwale.

Florence, Col.—The board of trustees of the town of Rockvale has granted to the Arkansas Valley Electric Company, of this city, a franchise to furnish electricity for light and motive power.

Forrest City, Ark.—W. H. Partridge has acquired a half interest in the electric light plant here.

Galion, O.—The Crawford Gas & Electric Company of this place, with a capital of $150,000, has been incorporated by S. N. Blake, R. P. Jenks, R. O. Morgan and others.

Harrisburg, Ark.—The town council has granted a franchise to the Harrisburg Light Company for an electric light plant. Lonnie Boone and Dr. J. M. Steele, of Greenfield, are interested.

Hillburn, N. Y.—An effort is being made and with a fair show of success to organize an electric light company to light Chester, Monroe, Central Valley and Highland Mills. The company will be affiliated with the Rockland Electric Company of this place, and will probably be called the Orange & Rockland Electric Company. The proposed capital is $30,000.

Luverne, Ala.—The Luverne Electric Light & Water Company, with a capital of $10,000, has been incorporated by J. R. Horn, J. M. Cody, R. G Reddach and others.

Lynchburg, Va.—This city is considering the establishment of an electric light plant to cost $40,000.

Lyons, Neb.—Bonds to the amount of $10,000 will be issued for the purpose of purchasing or installing an electric light plant.

Northwood, Ia.—The manager of the Northwood electric light plant contemplates the installation of an engine, two generators and a switchboard apparatus.

Oklahoma, Okla.—The Poteau Electric Light Company, capitalized at $10,000, has been incorporated with Malcomb E. Rosser, president; Edmond McKenna, W, A. Campbell and others.

Pana, Ill.—Eastern capitalists have purchased the electric light plant here.

Ponca, Neb.—On April 4 the citizens will vote on the proposition of bonding the city to the extent of $6,000 for the purpose of putting in a system of electric lights.

Port Lavaca, Tex.—Spittal Brothers, operating an electric light and ice plant, will install machinery for doubling the present capacity,

Syalcauga, Ala.—This city has engaged Arthur Pew, of Atlanta, Ga., to prepare plans for a waterworks and electric light plant, for which $20,000 in bonds have recently been voted.

Tekamah, Neb.—The citizens have voted to issue bonds to the amount of $10,000, for the purpose of installing an electric lighting plant, to be owned and operated by the city.

STREET RAILWAYS.

Delaware, O.—It is reported that the proposed electric line from Mansfield to this city has all the necessary financial means.

Des Moines, Ia.—W. S. Porter has had completed the preliminary surveys for a portion of the electric line he proposes to build in conjunction with the Polks between here and Nevada.

Elmore, O.—The officials of the Toledo, Port Clinton & Lakeside Electric Railway Company have been made a proposition to locate the power house and car barns of the company in this place

Findlay, O.—This city is endeavoring to secure the right of way for the North Baltimore, Bloomdale & Eastern Electric Railway.

Guadalajara, Mex.—An American syndicate, to be capitalized at $3,000,000, is said to be negotiating for the purchase of the street railways here, which are now operated by mules. The interests to be purchased include the concession for an electric street railway system, an electric lighting plant, and a large hydro-electric power plant at Juanacatlan and the transmission line to this city. Ramon Alcazar is one of the principal stockholders in La Electro Company of Guadalajara, which is part of the system involved in the purchase.

Harvard, Ill.—Another electric line will be erected to connect with the Chicago, Harvard & Lake Geneva Road in this city.

Independence, Kan.—The Union Traction Company has purchased a site here for the erection of a power house.

Long Island City, N. Y.—Each of the five sub-power stations building for the Pennsylvania Railroad Company in connection with the introduction of electricity as a motive power on the short lines of the Long Island Railroad, are to be connected with the main power house in this city, by means of three heavy copper wires.

Madison, Wis.—The Madison Traction Company has been purchased by F. Warren Montgomery, of New York. The property is valued at $500,000. F. Warren Montgomery, Jr., a son of the purchaser, will manage the system.

Missoula, Mont.—J. R. Wharton, of Butte, has applied for a franchise for the maintenance and operation of an electric street car system in this city.

Omaha, Neb.—It is stated that an electric line will be built between this city and Fort Crook.

Vermilion, S. D.—Farmers in the northern and eastern part of Clay County are very enthusiastic over the proposed electric railroad that is to be operated between Sioux City and Volin, S. D.

Zanesville, O.—The Muskingum, Coshocton & Tuscarawas Electric Railway Company, with an initial capital stock of $10,000, was lately granted a charter by the department of State. The road will be confined to Muskingum, Coshocton and Tuscarawas Counties, with this city and New Philadelphia as the termini. The incorporators are J. J. Adams, W. T. Koontz, F. S. Mooney, J. R. Alexander and H. I. Buell.

POWER PLANTS.

Chicopee, Mass.—Plans have been prepared for an electric power plant for the Dwight Manufacturing Company.

Knoxville, Tenn.—It is reported that the Knoxville Power Company is completing arrangements for the erection of its proposed power plant.

Tahlequah, I. T.—A plan has been developed to dam the Illinois River and establish a large power plant for this place. The Illinois is a mountain stream within two miles of town, and there is sufficient fall in it to get a good head for water power without a very expensive dam.

BIDS WANTED.

Dallas, N. C.—The town commissioners want bids on the installation of an electric light plant, 25 to 40 hp. J. C. Puett, mayor.

De Pere, Wis.—Sealed bids will be received by the board of trustees for the construction of the proposed electric lighting plant at the County Insane Asylum.

Dillard, N. C.—C. A. Mitchell, of this place, wants a good second-hand, 12 or 15 hp. boiler on skids.

Louisa, Ky.—A. Snyder, president of the Louisa Canning Factory, wants prices on a 40 hp. boiler.

Morganton, N. C.—The State Hospital located here wants three 150 hp. boilers.

Tuskegee, Ala.—This town will want complete equipment for an electric light plant of 800 to 1,000 16-cp. lights, including boiler and engine of about 60 hp., dynamo, wire, etc. Address W. H. Crawford.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 15⅛@15¼c.; Lake 15¼@15⅜c.; casting, 14⅞@15c.

The General Electric Company's quarterly dividend of 2 per cent. will be payable April 15.

It is said that the Philadelphia Electric surplus for 1904 will be $700,000 beyond interest charges.

The general offices of the Allis-Chalmers Company are to be removed from Chicago to Milwaukee May 1.

The Capital Traction Company of Washington, D. C., has increased its annual dividend rate from 5 to 6 per cent.

The $50,000,000 Chicago Subway Company will make its first railroad terminal freight connection within the next 30 days.

It is stated from headquarters that the gross earnings of the Bell Telephone Companies last year were something more than $80,000,000.

The Electric Storage Battery Company declared the regular quarterly dividends of 1¼ per cent. each on its preferred and common stocks, payable April 1.

The Westinghouse Electric & Manufacturing Company has declared the regular quarterly dividends of 2½ per cent. each on its preferred, assenting and non-assenting stocks, payable April 10.

An application has been made to the Rhode Island General Assembly for the incorporation of a company, to be capitalized at $1,000,000, to build an electric railroad from Narragansett Pier to Point Judith.

Indications are that for the second quarter of the fiscal year of the Massachusetts Electric Companies, ending March 31, gross earnings will show an increase of over $100,000 and that the earnings for the quarter will show a larger gain.

It is reported that the $10,000,000 bonds of the Philadelphia Rapid Transit Company will be underwritten at 98½ and interest. The bonds will run for 50 years and bear interest at the rate of 4 per cent. The underlying syndicate extends to March 1, 1906.

Kidder, Peabody & Co. have been delivering American Telephone & Telegraph Company's 4 per cent. gold bonds for some days, especially to New York. To date, the American Tel. & Tel. Company has received approximately $16,000,000 from the sale of the bonds.

President McMillin, of the American Light & Traction Company, in his annual report to the stockholders says that the earnings of the company increased 6.54 per cent. over the preceding year and the expenses decreased 37.81 per cent., giving a net gain in profit equal to 7.82 per cent.

The New York City Interborough Railway Company has received the approval of the New York State Board of Railroad Commissioners on its application to increase its capital stock from $400,000 to $5,000,000 and to issue a mortgage for $5,000,000. The company was also granted authority to use the overhead electric trolley. The company is to operate lines throughout the Borough of the Bronx.

The Metropolitan Street Railway Company of New York will technically not pay a dividend for the current quarter, but on April 15 it will distribute to shareholders of record on March 24 their proportion of the rent received for their property from the New York City Railway Company, which will be at the rate of 1¾ per cent. on the stock. In this the company and stockholders save the tax on dividend.

EDITORIAL NOTES.

Proposed Subways. Plans for rapid transit in Greater New York would seem to be like a wedding ring, "without beginning and without end." And yet the gigantic undertakings in this line which are now being projected are not surprising when we bear in mind that the population in this vicinity is increasing at the rate approximately of 15,000 a month. In other words, facilities or means have to be provided for carrying in a year 180,000 more persons than now, or, in five years, 900,000 more people.

It is no wonder, then, that there is talk of spending $300,000,000 in the no very distant future for new subways and tunnels. The plans which are expected to meet the demands of New York City for many years to come have been submitted to the Rapid Transit Commission and will undoubtedly be approved by that body this week. The submitted plans provide for nineteen routes on the east and west side, crosstown and in the Bronx.

To just what extent the city may be called upon to finance the extension of the rapid transit system cannot be told until it is known how much private capital may be put in the work. Upon this point the report of the Plans and Contract Committee says:

"The estimated cost of the routes now proposed, and for which the committee believes there are probable bidders, will very materially exceed the means now available to the city for construction; but there is reason to believe bids may be anticipated which will only call for an amount of municipal investment well within the present ability of the city. As the time is now favorable from the city's standpoint for the making of contracts for several lines of railroad which seems to meet with the conditions laid down, the committee recommends that such routes, although distinct, should nevertheless be approved at the present time and together."

It is the opinion of the commission that contracts much more favorable to the city than those made when the first subway was built will now be obtained.

* * *

Commutation Observations by Oscillograph. Owing doubtless to the experimental difficulties there has in the past been a lack of data concerning the exact behavior of the current in an armature coil during the period that its ends are under a brush. The pre-determination of the commutation qualities of a given design has, therefore, been a matter of considerable uncertainty. The position is, however, now altered by the availability of the high frequency type of oscillograph, which enables us to obtain the commutation curve and flux distribution with little more trouble than the indicating of a steam engine. The rating of perhaps 50 per cent. of the continuous current machines manufactured is determined by commutation rather than by heating; also, the size and range of variable speed motors, the range of voltage on generators, and the whole design of turbo-driven machines are settled chiefly by whether the commutation is sparkless or not. For these reasons it is somewhat surprising that commutation curves have not been more often obtained by designers.

Mr. J. K. Catterson-Smith last year carried out some investigations with a view to recording by means of the oscillograph the actual manner in which the current is reversed during commutation, and he presented the results, a digest of which will be found elsewhere in this issue, at a recent meeting of the Birmingham section of the Institution of Electrical Engineers.

* * *

The Value of Method in Electrical Engineering

It is almost impossible to realize the extent of the rapid transformation that has occurred in so short a time in the science and application of electricity. This transformation is not to be regarded as the result of extraordinary conditions, but rather as an inward process taking place under the influence of persistent and vigorous experimenting. It can be construed in other terms as method, and as such belongs to a new and important category. It may be translated into the new language of commercial progress under the title of scientific manufacturing.

Science has been defined as organized knowledge. By this is meant the grouping of correlated facts under headings which represent a perfectly definite relationship to each other and to the central and crowning proposition of the total aggregation.

In other words, the method of science has become the method of manufacturers. Competition calls for the best possible product at a cost to the manufacturer that gives him leeway in the industrial struggle with his neighbor. His neighbor is engaged in the same effort as himself, and therefore both are required to operate with an amount of money, skill and brains that will lead to this possible though limited supremacy in this field Method, then, is in many respects the only distinguishing feature between one and the other. What this method may be, whether it lies in the line of scientific ability in the creation of the type of machine or other device, or in the development to its highest economic climax of the shop practice employed, is the balancing up of one man's wit against another's. Superiority may lead to swift advancement, and this to such broad and comprehensive applications of crystallized scientific ideas that enormous projects may be handled, their consummation leading to changes of general public usefulness in the ordinary walks of life. This has been the case, as far as the value of method is concerned, in the first feeble efforts to build an electric motor. Conceptions of how this could best be done, reviewed in the light of our present knowledge, can only be classed as chaotic. The first motor ran, but as a device which embodied only one idea, the principle of rotation by electricity. In all other respects it was as archaic and as imperfect as the early inscriptions to the philologist on the tombs of Egyptian kings or the rude carvings of primitive men to the magnificent ideals of the sculptor Rodin.

It was necessary at this period in the history of the motor to employ method in discovering those scientific principles so necessary to its ultimate perfection. And then, when it had reached a stage of development that entitled it to construction on larger lines, method was again necessary to find the best way to build and assemble the parts that constitute the complete machine. This is the dominant influence in electrical works to-day, and the triumphs it has achieved are from this standpoint more the triumph of method than those of discovery. The savant earns his fame by that peculiar organization of mind which leads him to suspect the operation of new laws. Here, he uses a function like Newton, Davy, Kepler, Faraday, Helmholtz or Kirchoff, through which a new way of thinking is promulgated. From one standpoint, the intellectual influence is the most beneficial of all, but from the more practical or material standpoint, the new way of working is the most beneficial of all. Method has spelled the word progress; it is the index finger pointing the way along the rocky road of experimentation and manufacturing.

The electrical engineer exists to-day because electrical engineering exists. And it is but a step to reason that electrical engineering is the direct outcome of method in not only the large and elaborately equipped laboratories of our colleges and universities, but in the great workshops that dot the face of this continent, busy with the practical problems of electric lighting, electric railroading and the electric transmission of power.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

Lord Kelvin is dangerously ill in London, the result of an operation for internal trouble which he underwent last week.

M. Emile Guarini, a frequent contributor to the columns of ELECTRICITY, has been engaged by the Peruvian Government as professor at the School of Engineering of Lima and at the new School of Arts et Metiers about to be opened.

The conventions of the Iowa Electrical Association and the Association of Electric Railways in Dubuque on April 19 and 20 promise to be the biggest held in the history of the organizations.

The national conference on standard electrical rules—composed of delegates representing manufacturers or operators of electric plants and underwriters—will hold a meeting at 55 Kilby street, Boston, Friday, April 21.

One of the principal features of Commodore Peary's plans for his coming trip in search of the North Pole, will be the establishment of wireless telegraph stations along his course to the north.

It is believed that the international commission suggested by the St. Louis Congress in the matter of international uniformity in electrical units will meet in Geneva or The Hague.

The New York Motor Club has decided to set aside June 7 each year to treat all the orphan children of the city to an automobile ride. It is thought more than 1,000 machines will be in line.

Electric motors will be used by the Swedish Government as an experiment on the State railways. If they are successful, the entire railway system of Sweden will be equipped with electric motors, and steam locomotives will be done away with. The Swedish Government proposes to use the powerful water falls of that country to create the electricity, as fuel is expensive and has to be brought from Cardiff, Wales.

The German Government has indefinitely postponed the international wireless electrical conference which was to be held in Berlin this month.

According to the Paris correspondent of the London "Telegraph," radium has been found near the village of Grury, in the French district of Autun, and the Department of Saone-et-Loire, the chief town of which is Macon. The discovery is only very recent, and mining operations are not yet advanced, but it is said that considerable quantities of pitchblende have already been taken out. The seam of mineral ore opened up appears to be abundant. The whole countryside is excited by the find and dreams of future wealth. The owners of the mine just excavated are confident that they have struck a plentiful layer of radiferous ore, so neighbors follow the operations with covetous wonder, and think of digging up their own fields in search of the precious pitchblende.

ELECTRICITY LEAFLETS.

BY NEWTON HARRISON, E. E.

Electric Railways.

Long Distance Electric Roads.—The adaptability of the overhead trolley system to this purpose is evident from even a superficial examination of practical conditions. The greater the distance between the power house and the end of the road the greater the cost of the system. This is true particularly with the old established method of using a direct current of 500 volts and an elaborate feeding system to reinforce the pressure and current. The capital invested per mile of track, including the cost of the power house, is the factor which in many respects limits the length of a line. Electric roads can be built to reach as far out into and across the country as steam roads, but the expense attached to such an experiment under present conditions of practice is too high to prove interesting to capitalists. Thus it becomes evident that applied science or engineering projects rapidly present a new phase of interest. They can only become established as definite propositions if their cheapness as well as practicability is expressed by reasonable limitations. Not only are long-distance roads desirable operated by electricity but they must also present the feature of high speed as well. In this last respect the adaptability of the motor is unquestioned, and recent experiments have clearly proven a superiority that fully bears out all such anticipations.

Within city limits the system in vogue is based upon the idea of sub-stations. The power originally generated is converted into a high pressure alternating current which is distributed to a series of sub-stations or transforming houses. From these parts feeding lines radiate to different points of the electric road, sustaining the pressure and leading, if necessary, to the further extension of the road. The longer the line the more numerous of necessity becomes these subsidiary stations and in consequence the expense of this reinforcement rapidly reaches very high figures. Yet this idea is the one which has exerted an extraordinary influence upon the development of electric roads for street railway purposes within large cities. It is the method employed by the Interurban Company of Greater New York and has proved of immense value from an economical standpoint as compared with the original system, devoid of such ramifications as sub-stations and necessarily limited in its zone of activity on account of the costliness of the equipment.

Sub-stations have paved the way for a healthier development of the electric street railway system; the flexibility of the alternating three-phase system aided by the application of rotary converters has placed electric railroading upon a broad and efficient basis. Great extensions of track, in fact, long distance roads, are not practical even with these improvements, because both theory and practice clearly indicate the necessity for a simpler system, and, what might be regarded as a corollary to this presumption, a much higher pressure.

Requirements of a Long-Distance Road.—These requirements can be tabulated as a series of conditions imposed by the financial and scientific aspects of the problem; they are

1—High pressure for transmission.
2—High insulation for the trolley line.
3—Low cost per mile of road.
4—Simple devices to control the car.
5—Construction, of a most durable character.

Though but part of the long list that a close inspection of the proposition would indicate these items are most important in the light of modern progress. To meet the first requirement in a practical and economical manner, experiments have been directed along the lines laid down by alternating current practice. It can be stated at present almost as a certainty that any great advancement made in electric railroad work will be by means of the direct application of the single-phase alternating current. A trolley line supplied with this form of energy at a high pressure can readily transmit its power to a car equipped with simple series motors, the iron of said motors laminated and the control of them obtained by very simple means.

Alternating current practice represents essentially the economical application of electricity over long distances. The great power transmission plants are the most prominent illustrations of this character. The combination of these ideas with those required for electric roads seems to be the drift of present experimentation. An alternating current single-phase electric road is in operation at present with a pressure in the overhead trolley wire and tracks of 16,000 volts. The greatest care was taken in the construction of this line to make every part of the system solid, durable and well insulated. In this case, instead of a series of expensive sub-stations with rotary converters and other accessories the power is sent direct with occasional reinforcement where necessary. The cost per mile of road is thereby greatly reduced and, in consequence, the earnings express a better financial relation to the cost of installation or total investment than could be obtained under equal conditions by the use of a 500-volt direct current system.

Third-Rail and Overhead Trolley Compared.—Comparison is frequently a better means of realizing the truth than mere description. The only difference between a third-rail and an overhead trolley system might be best expressed by the statement that one is an overhead trolley and the other is a ground trolley. In fact, no actual difference exists except in this respect, either in the character of the machinery employed or the transmission and distribution of the power. The advantage of solidly supporting a live conductor, namely, the third-rail, where it can not fall, is counterbalanced by the difficulty of insulating it and its direct danger to the public. The third-rail is best suited to elevated structures, to stretches of protected track, to tunnels, etc. Tabulating these applications, the case is presented as follows:

I.—ADVANTAGES OF THE THIRD-RAIL.
Solidity of construction.
Cheapness of construction.
Better conductivity.
Greater durability.
Accessibility.

II.—DISADVANTAGES OF THE THIRD RAIL.
Difficulty of getting good insulation.
Danger to life.
Exposed to snow and rain.
Requires frequent bonding.

III.—APPLICATIONS OF THE THIRD-RAIL.
Elevated structures.
Protected stretches of track.
Tunnels.

In contradistinction to these factors are the advantages of the overhead trolley system, with the exception of the necessity for bonding and the possible question of the safety of the overhead trolley as far as life and limb are concerned. The question of insulation is obviously an open one with greater advantages on the side of the overhead conductor. Climatic conditions, such as the effect of long continued rains, snows, and sleet storms, are obviously bad in both cases. At the best, the overhead system is comparatively delicate, and unquestionably doubtful where long stretches of road are to be equipped. Constant inspection would be one of the only remedies for this, backed up of course by the use of the strongest and most reliable construction and material.

The Sprague Multiple Unit System.—

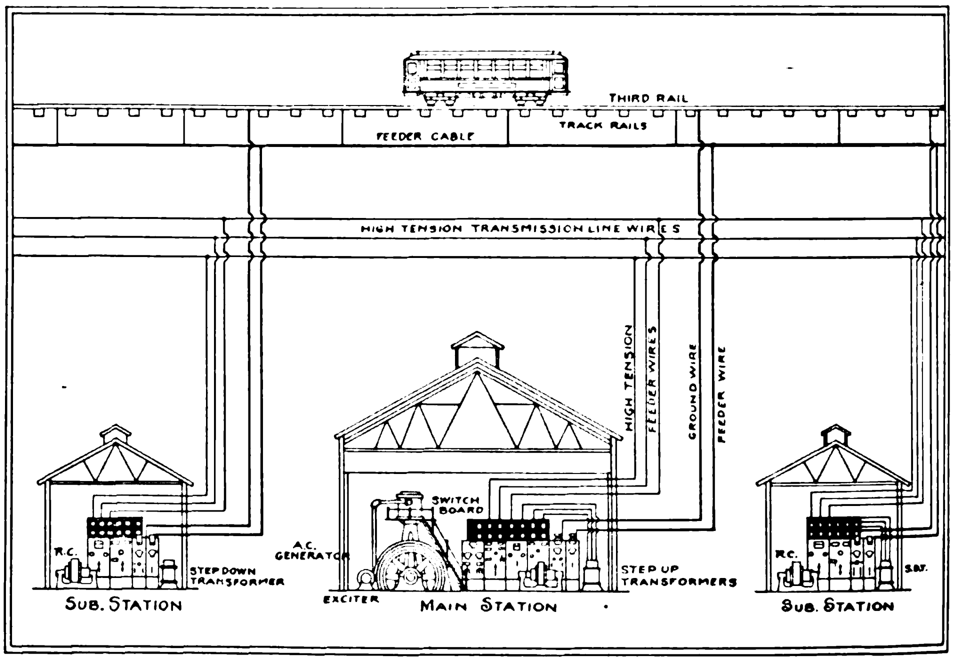
Whether trolley or third rail is employed, the system of coupling and uncoupling carried out in a steam road, must be duplicated in any electric system which hopes to successfully compete in the open field. The Sprague multiple unit system presents all these features, that is, the possibility of connecting an electric car to another, or a third or fourth, and having but one motorman exercising control over the entire train. This remarkable feature of electric control, the ability to couple up electric cars, each equipped with their own motor, and all under the management and subject to the will of one man, has greatly furthered the development of electric train service. Among the fathers of electric railroading, such as Daft, Van Depoele and Reckenzaun, no name shines so brightly as that of Frank J. Sprague. Both the elevated and underground systems employed in Manhattan Borough, New York, are multiple unit.

High Speed Electric Systems.—Systems of high speed electric service have appeared from time to time on paper, but few have ever reached a degree of crystallization entitling them to serious attention. The question of lubrication is always a serious one at high speeds; and the relationship existing between the weight of the car and the width and weight of the rails, is of supreme importance. The character of the road-bed must also be considered, and in conjunction with these things, the grades and declivities. Reciprocating engines, such as the locomotive, impair the road to a considerable extent in the course of a year. The absence of this pounding and the placing of the motors directly over the driving wheels in each truck is a most important point in favor of the electrification of steam roads.

In earlier days the motor was not sufficiently well constructed to stand the wear and tear of much travel. It was geared to the driving wheels of each car, and in consequence created a great waste of energy. The latest types of electric locomotives constructed for the use of the New York Central Railroad have their four driving motors so constructed that the extremities of the armature shaft are supplied with wheels, the power being thus directly applied. The motors are of 550 hp. apiece, four giving 2,200 hp. when in full operation. A speed of 70 miles an hour is readily acquired in this case, and even a speed of 90 miles under propitious conditions.

The speeds attainable in practice have reached their highest figures in Germany where a 100 miles stretch of road was repeatedly covered by an electric car at a rate exceeding 100 miles an hour. The peculiar construction of the series wound motor is such that its speed and torque can be readily increased by greater pressure and current. On the other hand, if gearing is used so as to advantageously employ any excess of torque the motor may develop to increase the rate of acceleration of the car, then high rates of speed are readily obtainable. The experimental phase of the problem has been successfully reached and passed, and the next stage to undertake is that of reducing the proposition to a more practical form. All of the mechanical objections are present which govern and perhaps limit high speed in a steam locomotive. These are air resistance, slippage, lubrication, etc., but whereas high speed cools a steam locomotive, and therefore diminishes its efficiency, the very opposite will result with a motor. The ability to increase the grip of the car upon the rails in electric cars by placing the motor, the main weight, where its power is most readily utilized, is a great feature in its favor in high speed railroading. At high speeds; such as 100 miles an hour or over, the air pressure is comparatively enormous and seriously impedes the motion of the car or train.

Large amounts of power must be on tap to insure the success of such a system, and of necessity the motors must be unusually powerful. Where a giant steam locomotive develops 1,000 hp. or a little over, an electric locomotive of equal size and weight would produce 2,000, and under a severe test 3,000 hp. This power translated into speed represents the extent, at present seemingly unlimited, which may be reached in the future. Provided the weight on the rails is sufficiently great, and the driving power is present, it is entirely within the province of reason and common sense to expect within the next decade speeds on specially installed electric roads reaching into the figures of 100, 150 and even 200 miles an hour.



The General Plan of a Modern Street Railway System.

General Plan of an Electric Road.—The principle on which an electric road is laid out operated by direct current, is based upon the fundamental ideas of

Generation of power.
Transmission of power.
Distribution of power.
Protection of the system.

The generation of the power involves a brief description of the station and its constituents. These are included under the head of those items familiar to the workers in power houses and bearing the title of

Steam plant.
Generating plant.
Feeding system.
Switchboard.
Lightning arresters.

The steam plant consists of boilers and engines with their accessories, and the generating plant of the dynamos alone. The feeding system includes the transmission, if it consists of rotary converters, sub-stations, transformers and feeders. The switchboard carries the measuring instruments, the switches, the feeders from the station, circuit breakers, and the lightning arresters. This in itself may be considered as consisting of apparatus connected to the generating section, metering section and feeding section. Thus the generation of the power, the transmission of the power, its distribution and the protection of the power house, lines and cars is accomplished by the application of principles of an elementary character, crystallized by necessity into that class of devices best suited to these new requirements.

Circuit Breakers.—The old-time fuse with its dangerous flash has been dispensed with, and in its place, the circuit breaker, or electro magnetic switch is employed. The circuit breaker may be inserted in either one pole or both according to its construction for the protection of circuits. A sudden rush of current energizes the magnet sufficiently to cause its pull to release a catch which releases the switch and it flies open propelled by powerful springs. Cars on a street railway line are all supplied with this form of protection against a short circuit. The feeders leading to the tracks and trolley, third rail or tee rails within the open conduit are similarly protected, and all of the power-bearing lines including the mains themselves.

Lightning Arresters.—The protection is not limited to these breakers, but is added to in the form of lightning arresters, to which any exposed system of lighting or power is particularly exposed. The idea of these devices is not only to direct lightning to the ground, but to relieve the line of any rise of potential, which would tend to threaten the insulation of the plant. These rises of potential are insidious in their nature, occurring without any manifestation of their presence, and absolutely requiring a vent or outlet in the form of an arrester, if the plant is to be saved from injury. The resulting dangers in this case arise from the possible grounds and short circuits which ruptured insulation would cause.

A NEW OPERATING DEVICE FOR AUTOMATIC REGULATORS.*

The usual method of automatically regulating the voltage of a circuit involves the rise of a delicate relay or contact voltmeter device for the purpose of setting the regulating apparatus (cell switch or resistance switch) in operation. A rise or fall in voltage from the normal deflects the voltmeter and closes a local circuit which starts the regulator in the correct direction for producing the required change in voltage. As soon as the normal voltage is reached again the contact is broken at the voltmeter and the regulator comes to rest in its new position.

For direct current circuits the voltmeter often takes the form of a solenoid connected across the voltage to be regulated, and acting on a tubular iron plunger suspended inside it by means of a spring. This plunger carries a contact arm free to make contact with one or the other of two fixed terminals, according to the position of the plunger in the solenoid. The position of the plunger is determined by the opposing actions of the magnetic pull due to the solenoid and the pull of the spring, and a definite position corresponds to every voltage across the solenoid. Any change in voltage causes one or the other of the forces to preponderate to an extent depending on the amount of the voltage change, and the plunger takes up a new balanced position. If a contact is to be closed by this movement, it is clear that the plunger must be arrested before the new balanced position is reached if there is to be any force available for making the contact. On this account only a fraction of the net increase in pull can be actually employed. Further, the total net increase in pull will itself be very small because the apparatus must be sensitive enough to act under voltage changes of the order of 1 per cent., so that only something like ½ per cent. of the total ampere turns in the solenoid can be employed for actually making the contact. The smallness of the actuating forces makes all such apparatus very delicate and the distances moved through are also very small, so that only very small currents can be dealt with at ordinary voltages. Similar objections apply to contact devices of the Deprez type, in which a coil carrying the current moves in the field of a permanent magnet, and also to those of the Ferraris type, used for alternating currents, in which a metal disk moves under the action of a revolving field against the action of a controlling spring. These objections have led to numerous attempts to solve the problem in other ways, but without much practical success hitherto.

The "Elektrotechnische Zeitschrift" describes a new device, recently put on the market in Berlin, which would seem to overcome most of the difficulties. In this instrument two ordinary horseshoe electromagnets are employed, one to cause increase in voltage when required, and the other to cause decrease in voltage. A single electromagnet would be useless alone, because of the wide difference which would exist between the exciting voltage, which just caused the armature to be attracted up, and that which just allowed the counteracting spring to draw it off again. On the other hand, an electromagnet can be relied on to make satisfactory contact when once the magnet actuating voltage is reached, for as soon as the magnetic pull overbalances the pull of the spring the armature moves towards the magnet, and so reduces the air-gap and increases the flux, which still further increases the pull. The armature is therefore drawn on with a rapidly increasing force in spite of no further increase in voltage occurring, until it comes in actual contact with the magnet, or, at any rate, until the required electrical contacts are securely made. By employing two independent magnets this desirable result can be insured for both decrease and increase of voltage from the normal, the magnets being set so that at normal voltage the armature of one of them is just on the point of being attracted up by the magnetic pull, and that of the other is just on the point of being pulled off by its spring.

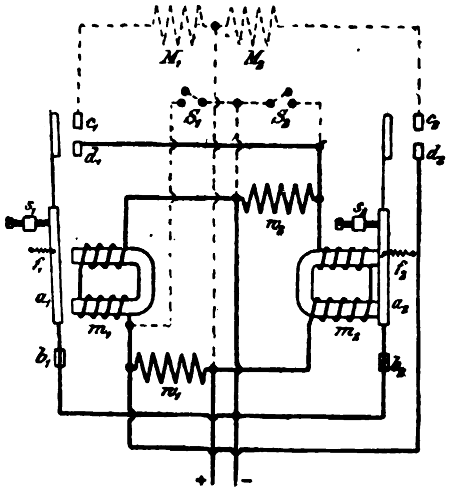


Fig. 1.

The actual connections employed with this apparatus are shown diagrammatically in Fig. 1; m_1 and m_2 are the two magnets connected to the supply (+ −) through the resistances, w_1 and w_2. m_1 makes contact when the voltage is above the normal, and m_2 when it is below the normal. The diagram shows the conditions existing at normal voltage. The adjustment of the screw s_1 and the spring f_1 determine the upper limit of voltage, and the adjustment of the screw s_2 and the spring f_2 determine its lower limit. Suppose that an excess voltage occurs. The first effect will be the drawing up of the armature a_1, connecting b_1, c_1 and d_1. This sends a current through the voltage adjustment apparatus, M_1, by means of which the circuit voltage is lowered, and at the same time the auxiliary switch, S_1, is closed. This short-circuits the magnet winding of m_1, and so allows the armature a_1 to fly back under the action of the spring f_1 into its normal position. This return opens the contacts c_1 d_1 and brings the voltage adjustment gear, M_1, back to its normal position and opens the switch S_1 again. In this way the original state is reached once more, with the exception that, in the meantime, the voltage has been lowered by the required amount, and so the armature a_1 will not be drawn up again. If, on the other hand, the voltage falls below the normal, the armature a_2 will be allowed to fall and contact will result between b_2, c_2 and d_2, and the regulating apparatus, M_2, will be energized. This raises the circuit voltage, and at the same time closes switch S_2, which short-circuits the resistance w_2 in series with magnet winding m_2, and so strengthens this magnet sufficiently to insure the armature a_2 being drawn up once more. This opens the circuit of M_2 and allows the voltage adjustment gear to return to its normal position and also opens the switch S_2, thus reaching the original condition again, with the exception that the current round m_2 is somewhat increased by the rise in voltage effected. The contacts d_1 d_2 form a safety device for insuring that both armatures shall never operate at the same time—for instance, owing to sudden voltage variations or to mechanical vibration of the instrument. When a_1 is drawn up, the operation of a_2 is prevented by the short-circuiting of the resistance w_2 through d_1 b_1. When a_2 is down, the operation of a_1 is prevented by the short-circuiting of the magnet winding M_1 through d_2 b_2.

---

*From the "Electrical Engineer," London.

The sensitiveness of the apparatus depends entirely on the accuracy of its construction. With the ordinary care obtainable in a manufacturing workshop, and the employment of flat steel springs for the armature supports, fine-thread adjustment screws at s_1 s_2, and long springs at f_1 f_2 (insuring their being stretched by only a small fraction of their length), voltage regulation within a fraction of 1 per cent. can be depended upon. Such accuracy is seldom required in practice—e. g., with cell switches the minimum steps which can be employed are of 1.9 volts each—but the fact that the instrument is capable of such fine adjustment insures accurate results, whatever the limits may be for which it is set. The contacts consist of copper and carbon, and are so solid in construction, and the pressure with which contact is made is so great, that the instrument can deal with currents of several amperes at 220 volts, and so can be used without additional relays for the operation of quite large motors. The large forces employed prevent the ordinary vibrations met with in engine rooms affecting the working at all, as they are liable to do in the case of the ordinary contact voltmeter devices, so that the apparatus can safely be mounted direct on the switchboard.

PROVIDING FOR INCREASE OF POWER IN ISOLATED STATIONS.

ARTICLE III.

BY W. H. WAKEMAN.

Fig. 3 illustrates another plan for driving dynamos that is in use in many stations. A medium speed engine with a stroke equal to about twice the diameter of cylinder is belted to a line shaft that extends the entire length of station. It carries pulleys which drive dynamos wherever wanted.

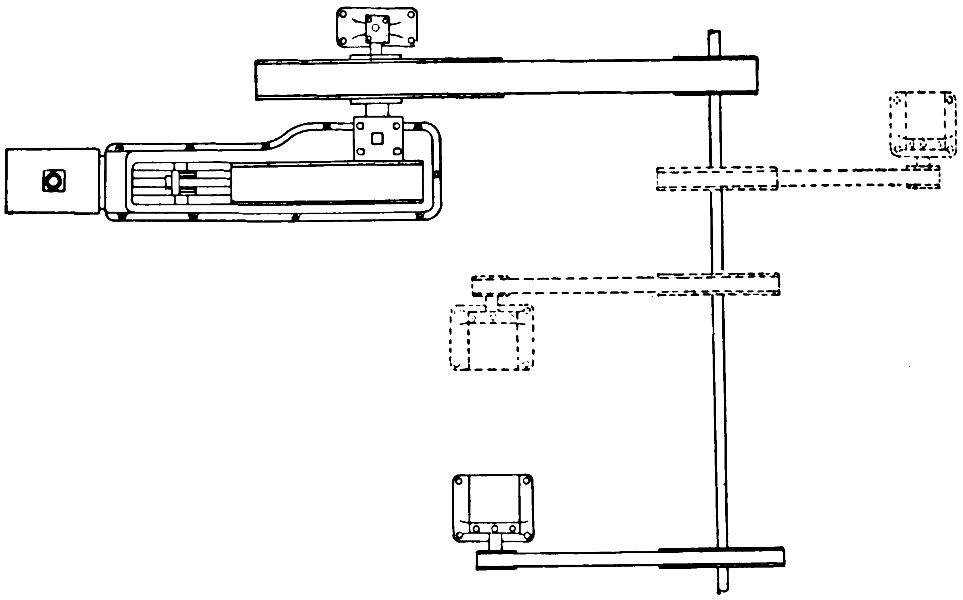

Fig. 3.

It will be well in this connection to state what is meant by a medium speed engine. Suppose that the diameter of cylinder is 20 inches and the stroke 42 inches, making the latter a little more than double the former. Assuming that this engine revolves 90 times per minute, the piston speed is 630 feet.

It is proper to rate 90 revolutions per minute as a medium speed, as 110 or more would be high and 70 or less would be low speed, but a piston speed of 630 feet per minute is high. If we compare it with a 12 by 12 inch engine at 300 revolutions per minute, giving a piston speed of 600 feet, it is at once apparent that it is high because every steam engineer rates 300 revolutions as high, yet the piston speed is less than for the lower rotative speed. From this reasoning it is plain that when an engineer speaks of a high or low speed engine he generally means the speed of crank shaft, and not of piston.

In Fig. 3 the full lines represent one large dynamo that is sufficient for the amount of current required when the station is new while the dotted lines show others that were added as the demands for electricity increased, thus calling for much more power than was wanted the first year.

A very good plan for providing the larger amount of power wanted may be described as follows: The boiler pressure is 75 pounds for the smaller load, but is increased to 100 or 110 as more power is wanted. At first the speed of engine is 70 revolutions per minute, with a main pulley on the line shaft the right diameter to give the required speed. It is increased from 70 to 90 revolutions by changing the governor pulley. In Fig. 4 the pulley on crank shaft 2 is 16 inches in diameter and we wish to have it revolve 70 times per minute. The governor pulley 3 will revolve 120 times per minute regardless of other conditions as that is the speed it was designed for, and it is stamped on the governor. Then 16 × 70 ÷ 120 = 9.3, which is the required diameter of governor pulley. As a general rule when it is desired to increase the speed of an engine the easier way is to change the diameter of governor pulley. I wish to emphasize the fact that the speed of governor remains constant, regardless of all other proper changes, as it is the standard. Engineers frequently remark that when a change is to be made the governor will run either slower or faster, but that is a mistake, and whenever heard it always denotes that the speaker is not well informed on the subject.

When more power is wanted in this case the speed is raised to 90 without changing the crank shaft pulley 2. Then 16 × 90 ÷ 120 = 12 inches, which is the required diameter of new governor pulley.

On some engines, as for illustration the Corliss, Greene, etc., it is possible to make slight changes in speed by altering the cut-off mechanism, but that is all wrong and should never be tolerated, for by so doing the average engineer will introduce dangerous conditions without knowing it, until a so-called "accident" results in which one or more lives are lost and much property destroyed. If the change is not worth making in a safe and proper way do not make it at all.

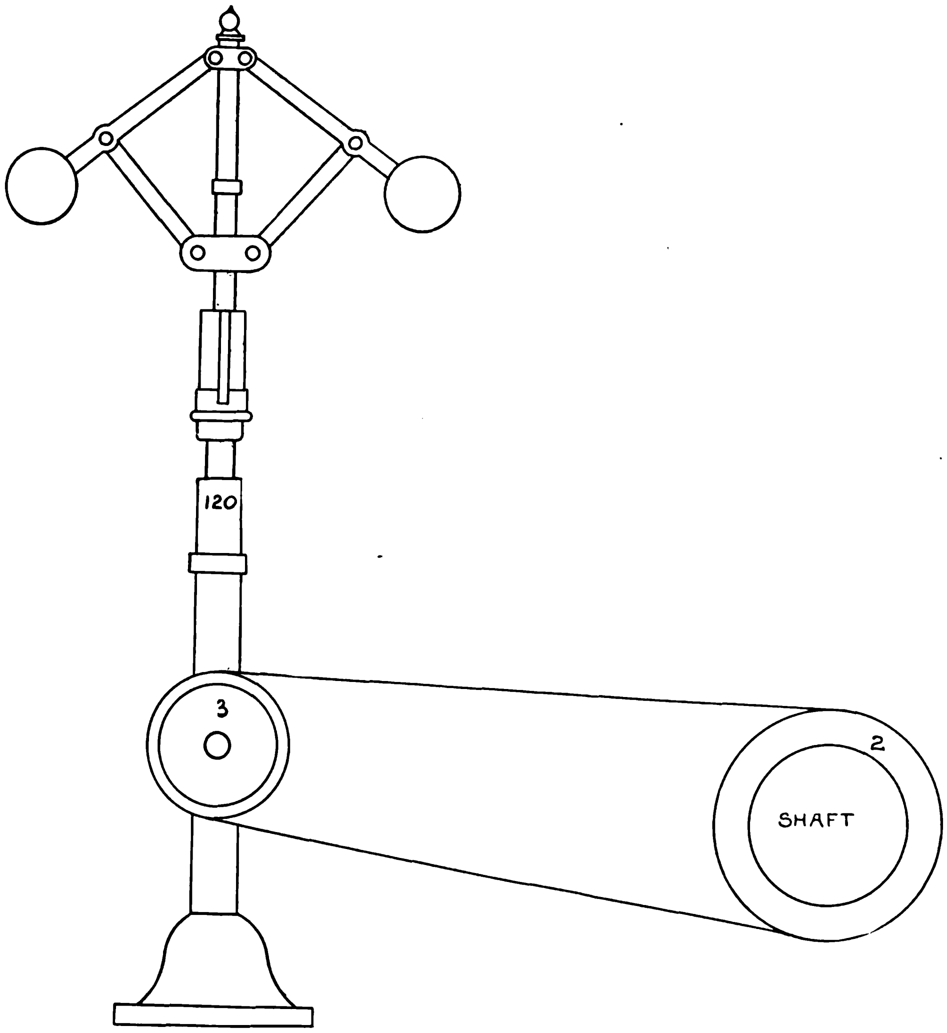

FIG. 4.

The speed of line shaft must not be changed, therefore the main pulley will be made larger, as that is probably the easier way to secure desired results. Suppose that the flywheel is 15 feet in diameter and while it revolves 70 times per minute, the line shaft should run 300 in the same time. The diameter of main pulley is then 15 × 70 ÷ 300 = 3.5 feet. The speed of engine is raised to 90, therefore the main pulley must be made 15 × 90 ÷ 300 = 4.5 feet in diameter.

When such a change was to be made in "the good old times," it was customary to bore many holes through the rim of pulley and bolt on wooden blocks made so as to nicely fit the circle. If one course was not sufficient, more was fastened to this until the required diameter was secured. This plan is all right so long as the blocks do not shrink and work loose, which they are almost sure to do sooner or later, thus becoming a constant nuisance, and sometimes a source of danger to all concerned.

The modern way is to take bolts out of the main pulley, if made in halves, or split it off if made solid, and put on a new steel pulley with wrought-iron rim. As this is in halves it requires but little time to make the change.

BLAST FURNACE GAS ENGINES FOR ELECTRIC POWER GENERATION.*

One of the largest generating stations in which the motive power is supplied by gas engines using the waste gases from the blast furnaces is that erected at the Phœnix Iron and Steel Works in Laar, near Ruhrort, Germany. By the courtesy of the management we are able to publish a brief description of the installation. At present the generating plant consists of three 1,000 hp. sets, while three other sets of 800 hp. each are in course of erection and are expected to run this spring. These gas engines are directly coupled to three-phase alternators, built by the Allgemeine Elektricitats-Gesellschaft of Berlin. The larger sets run at a speed of 100 revolutions per minute, but the three 800 hp. sets are to run at 140 revolutions per minute, this speed being chosen to enable the use of existing dynamos.

Fig. 1 shows the approximate calorific value and composition of various kinds of power gases used for gas engines. The production of every ton of crude iron liberates, we are informed, about 88,000 cubic feet of blast furnace gas, having the composition shown in the diagram and a calorific value of some 85 to 110 B.T.U. per cubic foot.

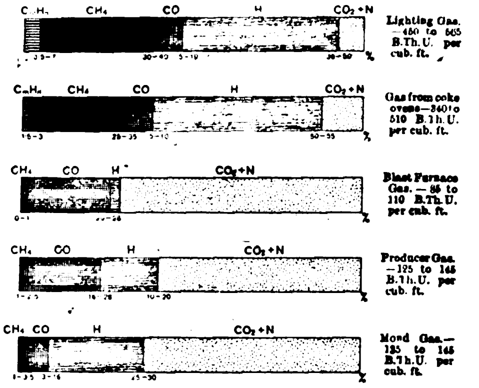

FIG. 1.

Charts Showing Composition of Various Gases.

After leaving the furnace, the gas is freed from its coarser impurities by passing through a number of ventilators into which water, in form of a spray, is injected. The gas is then forced by two other ventilators into the scrubber plant, where it first passes through two cylinders against a finely divided stream of water, and then flows through two coke scrubbers into the main gas pipe. After leaving the scrubber plant, it is stated that one cubic foot of gas contains only about 0.00875 grain of dust and from 4 to 6.5 grains of water.

The gas main runs along one side of the engine room, a separate pipe connecting it with each of the gas engines, which are placed side by side in the building. Each of these short connecting pipes terminates in an iron receptacle, interposed for steadying purposes. From these the gas flows to the mixing chambers on top of the engine. Fresh air is drawn into the mixing chamber from a system of underground tunnels. Current for the electric ignition is normally taken from the continuous current lighting mains, but a storage battery is provided as a stand-by and may readily be switched on to the ignition device by a two-way switch.

The engines were built by the Nurnberger Maschinenbau-Gesellschaft, and are illustrated in Figs. 2, 3 and 4. They work on the Otto cycle, but with two double-acting cylinders mounted in tan-

dem. In order to diminish the thickness of the piston rods as much as possible they are machined in such a way as to be curved slightly upwards before weighed down by the pistons. The weight of the latter is just sufficient to straighten the rod when the piston is at the center of its stroke. In order to facilitate access to the crosshead the cast-iron frame which supports the crank shaft bearings is built low, but is strengthened by substantial stays of round iron, as shown. Since the principal pressure on the crosshead has a downward direction, it was only necessary to provide lower slide bars, but any upward motion of the crosshead is made impossible by suitable guides. To avoid all deformation the cast-iron cylinders are symmetrical in form, and the water jackets are provided with a number of large openings for facilitating the removal of deposits. To obtain perfect cooling the water jackets are so arranged and dimensioned that the incoming cooling water first flows quickly past the hottest parts of the engine, and then gradually slows down as the cooler parts are reached. The covers at each end of the cylinders are also water-cooled but they can be easily removed leaving the interior of the cylinders and the valves open for inspection and cleaning. At each cylinder end there is an inlet valve at the top and an exhaust valve at the bottom, the latter being water-cooled. The piston is as short as compatible with safety, and is fitted with piston rings of cast-iron. It, too, is artificially cooled, the water being conducted to and from it through the piston rod, which is hollow and of crucible steel. The bearings of the crank shaft, the glands of the piston rods and the slide bars are lubricated by oil under pressure. Each gland has its own oil pump. The main bearings as well as the motion block of the crosshead are lined with white metal. All the valves are of the "poppet" type and the speed of the engines is governed by varying the explosive mixture. The valves are actuated by a lever arrangement, which itself is set in motion by a number of eccentrics. These eccentrics are keyed to the half-time shaft which carries a small flywheel of its own and is driven through gearing from the main shaft. There are special oil pumps for lubricating the cylinders and for lubricating the spindle of the exhaust valve. The lubrication of all the external parts, however, is done by gravity, the oil being fed to the different parts through large sized tubes from a common tank fixed in a high position. All superfluous oil is collected in a tank in the cellar, cleaned from all coarse impurities and pumped back into the oil tank in the engine room. Grease is used for lubricating the eccentrics and parts of the governing mechanism.

The cooling water is fed to the different parts under a pressure of about 20 feet, but special pumps are required for forcing the water into the moving shaft and piston. The cooling water which flows out of the engine at various points may be regulated in volume at these different points so as to obtain the desired cooling with the minimum of water. There is also a valve in the main water pipe which is used when starting or stopping the engine. For an initial temperature of the water of about 60 degs. F. and a final temperature of some 105 degs. F. the quantity of cooling water required per brake horse-power hour is stated to be about 6½ gallons.

The engines are started with compressed air.

It is claimed that every brake horse-power hour produced by the engines corresponds to an expenditure of from 8,700 to 10,300 B.T.U. only.

The dynamos driven by these gas engines generate three phase current at 2,000 volts and 47 cycles per second. They work in parallel and supply electricity for power and light to the various parts of the works, where the pressure is reduced to 200 volts by transformers. A

1,200 hp. motor (capable of withstanding 50 per cent. overload) is being installed, in addition, for driving the rolling mills. It will be supplied with current directly from the 2,000 volt mains, and will run at 130 revolutions per minute at full load. The motor is directly coupled to the finishing rolls, but drives the roughing-down mill by ropes. The rolls—which produce light mining rails, sleepers, angle iron and joists of all descriptions, from blooms weighing 800 pounds to 2,200 pounds and of 8 square inches section—consist of roughing-down rolls and one finishing train. The roughing-down trains are of the three-high type with one housing, and have rolls 2 feet in diameter which rotate at 100 revolutions per minute. The finishing train, on the other hand, is of the three-high type with three housings. Its rolls have a diameter of 1 foot 8 inches, and rotate at 130 revolutions per minute as already mentioned.

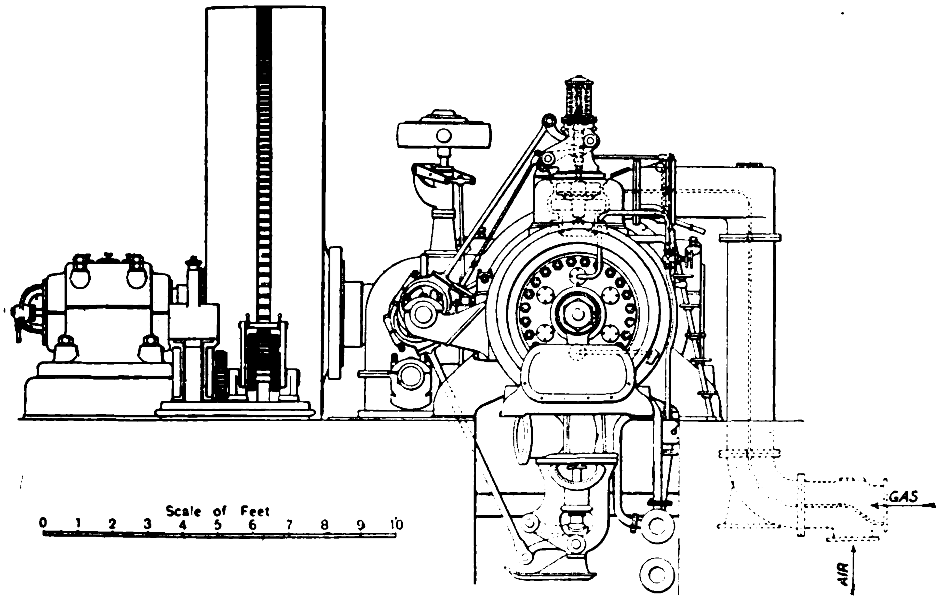

Fig. 4.—End View of Phœnix Gas Engine.

ELECTRIC SMELTING OF IRON AND STEEL.

Before the London Faraday Society at its last meeting a paper on "Recent Developments in Electric Smelting in Connection With Iron and Steel" was read by Mr. F. W. Harbord, who acted as metallurgist to the Canadian Government Commission which went to Europe last year to investigate thermo-electric processes. The author divided electric smelting furnaces into three main classes—induction furnaces, resistance furnaces and arc furnaces. The first type is specially adapted for melting rather than smelting; the others can be adapted for either purpose.

(1) INDUCTION FURNACES.

The best known furnace of this type is the Kjellin furnace. This is, in effect, a step-down transformer, in which the contents in the hearth form the secondary circuit of the transformer. Any grade of steel, from 0.10 to 1.50 per cent. carbon can be produced in this furnace, but high-class materials must be used, as there is no elimination of impurities. The furnace at Gysinge, in Sweden, which has been in operation since 1900, is now of 175 kw. capacity, and its output is 5.2 to 5.5 tons per 24 hours. The furnace absorbs from about 0.13 to 0.16 EHP.-year per ton of ingots, according to the carbon content of the product.

(2) RESISTANCE FURNACES.

(a) The Heroult Furnace.—A four-ton furnace at Kortfors, in Sweden, and a somewhat smaller one at La Praz, in France, are producing high-quality steel on a considerable scale. The furnace is a tilting one and is basic lined; two large adjustable electrodes pass vertically through the roof. In this furnace ordinary steel scrap can be converted into steel of the highest quality, the impurities being removed by suitable fluxes. Steel varying from 0.079 to 1.000 per cent. carbon is made with perfect ease. At La Praz an alternating current of 4,000 amperes and 110 volts is used. The furnace absorbs about 0.111 EHP.-year per ton of ingots in the case of low-carbon steel and about 0.17 EHP.-year for high-grade carbon steel.

(b) The Keller Furnace.—This is similar to the Heroult furnace, differing only in details. The author saw tests made with a 35-cwt. experimental furnace at Livet. Common scrap was the raw material and the energy absorbed was about 0.120 EHP.-year per ton of ingots.

(c) The Resistance Furnace for Direct Smelting from the Ore.—Experiments made at Livet in the Keller furnace demonstrated the possibility of making pig of the most varied composition. The type of furnace is identical with that used for making iron alloys, such as ferro-chrome, ferro-tungsten and ferro-silicon. The furnaces at Livet are vat-shaped and connected at their lower ends by a central well; four are usually grouped together. The current used in the trial runs varied between 10,600 and 12,000 amperes, at voltages from 63 to 68, and the energy absorbed was 0.25 hp.-years per ton of pig for a white iron containing little silicon and manganese, and 0.53 hp.-years for a grey iron more silicious. The coke used averaged 767 pounds per ton of pig-iron produced, and the estimated cost of electrodes was 87 cents per ton of iron.

At Livet 45 to 60 per cent. ferro-chromes and 25 to 80 per cent. ferro-silicons are made regularly. For such high-grade alloys the electric furnace is more economical than the blast furnace.

The Gin Process.—In this it is proposed to dispense with carbon electrodes, using instead large water-cooled block terminals, which lead the current into a long, basic-lined narrow channel, forming the furnace hearth. The author does not know whether the process has been tried on a commercial scale.

(3) ARC FURNACES.

The heat is obtained from direct radiation from the arc, and by reflection from the roof and sides of the furnace.

(a) The Stassano Furnace—The latest type at Turin is a five-ton furnace (per 24 hours) and absorbs 4,900 amperes at 150 volts, the current being distributed between two arcs (and therefore four electrodes) which meet at the center of the furnace. The furnace is lined with magnesia bricks. Steel is produced direct from the ore (pure hæmatite) in one furnace. Reduction is effected only by the carbon, which, with the ore, is moulded into briquettes, and a practically pure iron can be obtained. The energy consumption is 0.186 EHP.-years per ton of steel, and the consumption of electrodes 5 kg. per ton of steel.

(b) The Harmet Process—In one form of furnace the inventor melts oxides of iron in a vertical shaft by means of producer gas, and reduces them by solid incandescent carbon; in another form carbonic oxide is his chief reducing agent. The process has not yet been experimented with on a commercial scale.

GENERAL CONCLUSIONS.

(a) Steel, equal in all respects to the best Sheffield crucible steel, can be produced even in this country, either by the Kjellin, Heroult, or Keller processes, at a cost considerably less than the cost of producing a high-class crucible steel, assuming electric energy to cost $50 per EHP.-year.

(b) At present, structural steel, to compete with Siemens or Bessemer steel, cannot be economically produced in the electric furnaces, and such furnaces can be used commercially for the production of only very high-class steel for special purposes.

(c) Speaking generally, the reactions in the electric smelting furnace are similar to those taking place in the blast furnace. By altering the burden and regulating the temperature by varying the electric current, any grade of iron, grey or white, can be obtained and the change from one grade to another is effected more rapidly than in the blast furnace.

(d) Pig iron can be produced on a commercial scale at a price to compete with the blast furnace, only when electric energy is very cheap and fuel very dear. With electric energy at $10 per EHP.-year, and coke at $7 per ton, the cost of production is approximately the same as the cost of producing pig iron in a modern blast furnace. Under ordinary conditions, where blast furnaces are an established industry, electric smelting cannot compete; but in special cases, where ample water-power is available, and blast furnace coke is not readily obtainable, electric smelting may be commercially successful.

COMMUTATION OBSERVATIONS BY OSCILLOGRAPH.

Mr. J. K. Catterson-Smith, in his paper presented in England before the Birmingham section of the Institution of Electrical Engineers on March 15, gave figures of records taken with a Duddell pattern oscillograph, of the actual current in one particular coil on the armature of a small four-pole Westinghouse rotary converter which was used as a 6 hp. shunt motor running at 1,200 r.p.m. on a 110 volt circuit. The output was measured by means of a brake on the pulley, and as far as possible observations were made at full load, but the time taken in recording the shape of the commutation curve in the brush-shifting experiments, the burning up of the brake band and the excessive sparking on the commutator, made it imperative to work at half load. The method for observing the current was this: the armature circuit was cut at a point remote from the commutator, and the two ends of the coil thus exposed were connected to a pair of slip rings, the brushes on these rings being joined together by a strip of manganin sufficient to give about ¼ to ½ volt drop at full load; the oscillograph was connected across this strip and thereby showed the current in that particular coil at any instant.

The curves obtained showed very clearly the desirability of using as narrow a brush as possible on a motor with a large polar arc in which the neutral zone is small. A wide brush soon has one or other edge in contact with conductors in a comparatively strong field, which will certainly produce heavy short-circuited currents. The increased loss which results through a wrong brush position, and which goes in increased heating of the armature and commutator, was indicated by certain of the curves.

The calculation of the reactance voltage of a coil undergoing short-circuit is now usual in designing a continuous current motor. Mr. Catterson-Smith's commutation curves showed that in all probability the sine curve is rarely to be met with, and that the method of calculating the reactance voltage gives little more than a guiding figure; however, as a guide, that figure is very useful, especially in the comparison of similar types of machines.

The best practice was stated to be to design a machine with its reactance voltage less than the brush drop whenever possible, especially with reversible motors having a fixed brush position. The reactance voltage of small machines with stiff fields should be kept below 2.0 volts, which may be increased to 3½ for large machines; but for variable speed motors, etc., which have to work with very weak fields, there is no reversing field to help the commutation, and the reactance voltage must be kept below 1.0. Of course these figures do not apply to machines having special commutation poles.

COMMERCIAL SUCCESS.

It has been remarked, and with truth, that one of the secrets, perhaps it may be termed the chief secret, of commercial success is enthusiasm, wisely directed, of course. The business man who strives to invest his duties, day by day, with the spirit of enthusiasm, may be said to give his day's task a good "set-off," as it were, while he is likely to get through his work with less expenditure of nerve-force, and with a greater degree of pleasure to himself than if he started in an indifferent or dull frame of mind, as many business men are, unfortunately, so often accustomed to do.

The foregoing observations may truthfully be said to apply to every branch of business, including that of engineering. This is a "point" which the young engineer should take careful note of. He should remember that our great engineers and inventors did not achieve distinction merely by dogged application to the task on hand, but likewise by the enthusiastic way in which they, as a rule, went about their respective work.

Some of our eminent living engineers, electricians and inventors (whose names might easily be adduced), are noted for the jubilant spirit with which they invariably invest their labors. They appear to find a perennial pleasure in their work; and that is exactly what everyone, the academically-trained professional, commercial men, and artisans alike, ought ever to strive to do. They will thereby be able to find pleasure—nay, even delight—in the performance of their work, whatever it may be We are quite well aware of the fact (and it is an ugly fact, too), that many men are to-day pursuing a calling for which they have no particular liking. Such unhappy souls are frequently heard to say that "they do not care for the work, but it is the only kind of business that they are qualified for." Such individuals, and we fear they are somewhat numerous, are assuredly to be pitied.

It is a pity for any man to have to follow a trade or profession which does not lie to his heart. He is not likely to attain distinction, nor even ordinary success, in his own sphere of labor. There would be fewer of this type of worker in our midst at this present hour if parents studied the "bent" of their children's minds ere apprenticing them to a trade. The natural taste of a child should always be allowed due weight when determining upon their future life-calling. Indeed, we do not know but that it should rank as a primary element in the matter, that is, assuming that the youth or girl is physically and mentally qualified to pursue the particular line of business towards which his or her native bent of mind points.—"Engineering and Iron Trades Advertiser," Glasgow.

New Submarine Boat.

Several experiments have recently been made at Camogli, near Genoa, Italy, with a new submarine boat. The craft is intended to recover objects from the bed of the sea, and for this purpose is provided with powerful hooked arms worked by electricity. So far the greatest depth reached is 58 fathoms, and at this the men were able to breathe and work freely.

Nominations by the Institute.

The board of directors of the American Institute of Electrical Engineers nominated the following ticket for the coming annual meeting: For president, Schuyler S. Wheeler, of Ampere, N. J.; for vice-presidents, Charles A. Terry and Townsend Wolcott, of New York, and Gano S. Dunn, of Ampere, N. J.; for managers, C. C. Chesney, of Pittsfield, Mass., Calvert Townley, of New Haven, Conn., Bancroft Gherardi, of Brooklyn, and Charles L. Edgar, of Boston; for treasurer, George A. Hamilton, of New York; for secretary, Ralph W. Pope, of New York.

Electrical Horseshoe Magnet.

A dispatch from Boston, Mass., says that experiments have been made recently at the Allston shops of the New York Central Railroad with an electrical horseshoe magnet attached to a set of locomotive driving wheels to determine the degree of magnetic resistance it was possible to exert. It was found that with the attachment employed the adhesion was increased fully 35 per cent. The Central will have 30 of its locomotives fitted with the device, so as to do away with the use of sand.

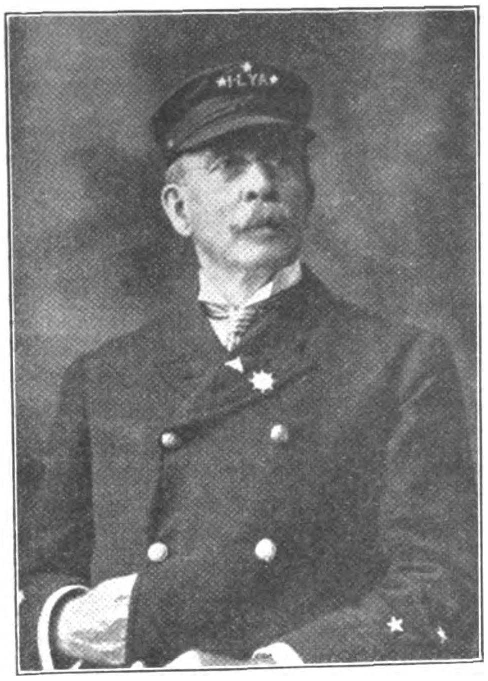
DEATH OF CHARLES C. WARREN.

Mr. Charles C. Warren, president of the Warren Electric Manufacturing Company of Sandusky, O., died at his home in that city on Wednesday, March 22, from a stroke of paralysis. He was nearly 70 years old.

Mr. Warren entered the electrical business in 1878 and from 1881 to 1890 he was the Western manager of the old United States Electric Light Company. He later managed the affairs of the United Edison Manufacturing Company in the West, outside of Chicago, until the fall of 1891, when he went with the Westinghouse Company.

In 1892 Mr. Warren together with his son, H. B. Warren, designed and patented an inductive type of alternating current generator, now well known as the Warren alternator. In 1896 the Warren Electric Manufacturing Company was organized and this company erected a plant at Sandusky for the purpose of building these alternators and other electrical machinery. Mr. Warren was president and general manager of this company at the time of his death and since the beginning has managed its affairs with an eye to the welfare of all connected with the company, whom he considered as members of his industrial family alike interested with himself in the common good.

He was an enthusiastic yachtsman, owning one of the finest yachts on Lake Erie, the Wemco II, and was honored with the office of commodore of the Interlake Yachting Association, composed of yacht clubs of Lake Erie. He was a Free Mason and a member of the Order of Elks, was identified with many local enterprises in Sandusky, and his death will be a serious loss to that city. He is survived by his wife and one son, Mr H. B. Warren.



CHARLES C. WARREN.

Large Cable Contract.

The Safety Insulated Wire & Cable Company has been awarded the contract for the cable for the Alaskan line and the cable for the fire control system, at its bid of $150,000.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED MARCH 28, 1905.

Electric Railways and Appliances.

785,758. Electric-Railway System and Conduit. George W. Olinger, Orchard, O. Filed June 19, 1903.

785,840. Car-Fender. Charles H. Turner, New York City, assignor of one-half to Will O. Turner, same place. Filed June 25, 1904.

785,891. Railway Block Signal Apparatus. Allen B. Kendall, Maywood, Ill. Filed Oct. 17, 1904.

785,909. Electric-Railway System. John O. McDonald, New York City. Filed Feb. 9, 1904.

786,148. Signal System for Electric Railways. Greenleaf W. Pickard, Amesbury, and Harold J. W. Fay, Westboro, Mass., assignors to the American Telephone & Telegraph Company Filed Jan. 28, 1905.

786,188. Trolley. James L. Brownlee, Pittsburg, Pa. Filed June 10, 1904. Renewed Jan. 31, 1905.

786,209. Electric Railway Signaling System. John D Gordon, Riverside, Cal. Filed May 5, 1904.

786,219. Trolley. Sando Kacso, Allegheny, Pa., assignor of one-half to David Hollander, same place. Filed Dec. 9, 1904.

Electric Lights and Appliances.

85,980. Electric-Arc Lamp. Ralph Scott, Wilkes-Barre, Pa., assignor of one-half to Marcus A. Miller, New York City. Filed Oct. 14, 1903.

785,997. Incandescent-Electric-Lamp Socket. George C. Baillard, Brooklyn, N. Y., assignor to the General Electric Company. Filed May 28, 1902.

786,231. Electric Lamp. George P. McDonnell, St. Louis, Mo., assignor to the American Electric Company, East Orange, N. J. Filed Jan. 5, 1905.

Electrical Machinery and Apparatus

785,700. Electric-Conductor Support. Johan M. Andersen, Boston, Mass., assignor to the Albert & J. M. Anderson Manufacturing Company, Portland, Me. Filed Jan 5, 1905.

785,703. Power-Transmitting Mechanism. William J. Bayrer, Hartford, Conn., assignor of one-half to Frederick R. Boynton, same place. Filed Feb. 29, 1904.

785,712. Electric-Cable Joint. Donald J. Chisholm, East Hampton, N. Y. Filed May 11, 1904.

785,731. Means for Converting Electrical Currents for Induction-Motors. Christian F. Heinkel, Cleveland, O. Filed Aug. 4, 1904.

785,797. Thermal Cut-out for Electrical Circuits. Frank B. Cook, Chicago, Ill. Filed March 9, 1904.

785,816. Indicating Apparatus for Motor-Vehicles. David Mason, New York City, assignor to John A. Woods, Brooklyn, N. Y. Filed Aug. 25, 1903.

785,817. Controlling Apparatus for Motor-Vehicles. David Mason, New York City, assignor to John A. Woods, Brooklyn, N. Y. Filed Aug. 25, 1903.

785,863. Electric Time-Switch. William B. Coulter, Waterbury, Conn. Filed Nov. 11, 1904.

785,948. Power-Transmission Mechanism. Magnus Hendrickson, Chicago, Ill., assignor to Jacob Lauth, same place. Filed April 4, 1904.

785,949. Double-Throw Electric Switch with Indicator. Edward M. Hewlett, Schenectady, N. Y., assignor to the General Electric Company. Filed July 11, 1903.

785,970. Means for Regulating Electric Circuits. Walter S. Moody, Schenectady, N. Y., assignor to the General Electric Company. Filed July 26, 1902.

785,994. Rheostat for Starting and Controlling Electric Motors. William C. Yates, Schenectady, N. Y., assignor to the General Electric Company. Filed Sept. 14 1904.

785,995. Winding for Three-Phase Motors. Ernst F. W. Alexanderson, Schenectady, N. Y., assignor to the General Electric Company. Filed Aug. 19, 1904.

786,008. Air-Brake Control. Fred B. Corey, Schenectady, N. Y., assignor to the General Electric Company. Filed Aug. 13, 1904.

Telephones and Telephone Apparatus.

785,728. Telephone System. Adolph C. Gilgen, Passaic, N. J., assignor to the New York Automatic Telephone Company, same place. Filed June 11, 1904.

785,754. Telephone-Exchange Apparatus. James L. McQuarrie, Chicago, Ill., assignor to the Western Electric Company. Filed May 27, 1901.

Miscellaneous.

785,803-804. Art of Transmitting Intelligence and System of Transmitting Intelligence. Cornelius D. Ehret, Rosemont, Pa. Original application filed Feb. 10, 1902. Divided and last application filed July 8, 1902.

785,832. Electrode for Electric Furnaces. Edgar F. Price, George E. Cox and James G. Marshall, Niagara Falls, N. Y., assignors to the Union Carbide Company, same place. Filed Oct. 19, 1903.

785,941. Compound Relay. Stephen D. Field, Stockbridge, Mass. Filed Jan. 14, 1905.

785,962. Production of Boron by Electrolysis. John A. Lyons and Edward C. Broadwell, Chicago, Ill. Filed Sept. 16, 1903.

786,005. Electric Protector Apparatus. Frank B. Cook, Chicago, Ill. Filed April 11, 1904.

786,016. Combined Electric and Mechanical Signal Apparatus for Elevators. William T. Dulany, Jr., Brooklyn, N. Y. Filed May 11, 1904.

786,017. Starting-Rheostat. Edgar F. Dutton, Schenectady, N. Y., assignor to the General Electric Company. Filed Nov. 13 1902.

786,024. System of Distant Electrical Control. Joel Gomborow, Lynn, Mass., assignor to the General Electric Company. Filed 15, 1904.

786,132. Wireless Telegraphy. Guglielmo Marconi, London, Eng., assignor to Marconi's Wireless Telegraph Company, Limited. Filed Oct. 13, 1903.

786,146. Electric Hammer. Louis Paulero, Petersburg, Va. Filed Sept. 22, 1904.

786,221. Process of Electrodepositing Metals. Edward D. Kendall, Brooklyn, N. Y., assignor of one-third to Edward N. Dickerson, Stovall, N. C. Filed Oct. 28, 1903.

THE TELEPHONE WORLD.

Telephone Extension for Northern New York.

The Clinton Telephone Company is preparing to extend Independent telephone lines throughout Northern New York, and will by early summer be giving service with the towns in the northern part of Clinton and Franklin Counties. The company has recently acquired the property of the Malone Independent Telephone Company, which gives control of the Independent service in Franklin County. Arrangements have been completed for building lines from Plattsburg to Champlain, Rouses Point, Mooers, Ellenburg, Chateaugay and Malone, thus giving complete service with the entire section.

The council of the village of Richwood, O., has refused for the second time to grant a franchise to the Central Union Telephone Company for an exchange in that village. It is said that the reason the council is not willing to grant a franchise is because Richwood men are interested in the Independent Telephone Exchange there and are opposed to another system.

The St. Louis, Mo., County Telephone Company has disposed of all its bonds issued so far for the purpose of constructing the system to J. H. Murphy. The details of the deal were completed at a meeting of the directors lately held at Clayton. It was also agreed that the capital stock of the company should be increased from $100,000 to $200,000. Webster Groves and Kirkwood will be supplied next.

The Owingsville, Ky., Telephone Company, owned by Henry Watson, of Mt. Sterling, in connection with W. J. Felt, of Salt Lick, will erect a telephone line from Salt Lick to Owingsville at once, connecting the latter place with all long-distance lines.

Clarence Kirwan, representing the Chesapeake & Potomac Telephone Company, of Baltimore, Md., has filed an application with the county commissioners for permission to extend the company's lines through the Fourth and Fifth districts.

The Keystone Telephone Company has issued a statement saying that it now has 17,000 'phones in use in Philadelphia, and that earnings are far ahead of last year. Its finances are in very much better shape than they were formerly.

The stockholders of the Jacksonville, Telephone Company have decided to immediately extend their line to Lonoke, Ark., and put in an exchange there.

The Wausau, Wis., Telephone Company has closed a contract for a 700-drop automatic telephone system. The change means an outlay of $30,000.

An Independent telephone line is being constructed by the farmers living east and south of Bristol, S. D.

A rural telephone company has been organized in Big Lake, Minn., and $1,500 in stock subscribed.

South Bend, Ind., is to have an automatic telephone system.

Rural Line for Fourteen Towns.

Citizens and farmers of the towns near New Ulm, Minn., have organized the New Ulm Rural Telephone Company. The purpose of the company will be to establish rural telephones in 14 towns adjoining New Ulm, in the counties of Brown, Nicollet and Blue Earth. Articles of incorporation were adopted, and the capital stock will be $50,000, divided into 2,000 shares. A large portion of the stock has already been subscribed. Officers were elected as follows: President, Philip Liesch, of New Ulm; vice-president, Alexander Russell, of West Newton; secretary, A. J. Vogel, and treasurer, Otto Schell, both of New Ulm. A director for each of the 14 towns was also elected. New Ulm will be the central point from which the rural lines will radiate. Steps were taken to begin the construction of the line, and it is expected to have it completed some time next summer.

At present the Minnesota Central Telephone Company, with headquarters at Wilmar, occupies the field at New Ulm. It is the purpose of the new company to connect with or purchase the local exchange. If these plans should fail, another local exchange will be built.

The Farmers' Mutual Telephone Company, having as its object the connection of the rural sections of Whatcom County, Wash., was lately organized. Ed. Brown, of Custer, is president; W. H. Townes, of Lynden, secretary, and J. C. Gillies, of Nooksack, treasurer. It is a co-opertive, pay-as-you go proposition, and no indebtedness is to be incurred. Work has for several weeks been progressing under the temporary organization, and already 50 miles of poles have been set by the farmers between Everson and Sumas, Sumas and Lynden, Custer and Ferndale, and Sumas and Nooksack. It was recently decided to place an order for two tons of wire, which will stretch about 50 miles. This will cost about $6 a mile, it is estimated. In Bellingham, Minn., and the rural towns, the Farmers' line is to connect with the Sunset Company's system. The company is working as an association.

A new enterprise to be known as the Oaks Corners, N. Y., Telephone Company is being carried into effect. The poles will be set up shortly. The system will extend a few miles in each direction, so that most of the residents will be in communication with Oaks Corners, and thence to many other places. Frank Wood is the president.

According to a recent announcement made by the Providence, R. I., Telephone Company, the rates for extension telephones will be reduced to $6 a year to subscribers, or just one-half of the present rate.

Thousands of dollars will be spent by the Mutual Telephone Company, of Shelbyville, Ind., in extensive improvements, among those contemplated being the installation of an entirely new underground system.

An Independent telephone company, capitalized at $15,000, has been organized at Milton, Ky.

A 25-year franchise has been granted to the Milford, Ia., Telephone Company.

Two Companies Consolidate.

The home office of the Wayne County Telephone Company, which has been in Clyde, N. Y., since the formation of the company 10 years ago by the Bishop Brothers, is to be removed to Lyons and consolidated there with the main office of the Wayne-Monroe system. This is a move in the direction of making the Clyde Independent telephone system in connection with the Wayne-Monroe system one of the most complete and satisfactory to be found anywhere.

A central energy plant to cost $4,000 is to be established in Lyons.

The village of Newport, N. Y., at a recent special meeting of its trustees, granted a franchise to the County Telephone Company, of Herkimer, a branch of the Utica Home Telephone Company, permitting the company to erect poles and wires in its streets. The company will build an exchange at Newport, from which the territory of the West Canada Creek Valley will be served. The villages of Cold Brook, Middleville and Poland will be reached by trunk lines. The exchange will have connections for 400 'phones. Construction work will begin as soon as conditions are favorable.

The Wyandotte County, Kan., commissioners have granted to the Monticello Telephone Company the right to string wires across the Bonner Springs bridge. This will give better telephone communication between the farmers on either side of the Kaw River.

At the annual meeting of the stockholders of the American Telephone & Telegraph Company, last Tuesday, the retiring board of directors was re-elected. The by-laws of the company were changed to conform with the laws, but otherwise only routine business was transacted.

The McLaurine Telephone Company, of Oak Grove, Mo., will install an exchange at Grain Valley, Mo. It will connect with Oak Grove, Lone Jack, Tarsney, Grain Valley and Blue Springs.

The merchants and farmers of Houstonia, Mo., have formed a telephone company and will put in an exchange there. M. P. Tuck is president, and Dr. C. L. McConnell, secretary.

The Churchville, N. Y., Home Telephone Company is making rapid and satisfactory progress with its line in that village.

The Commercial Club of Hanley Falls, Minn., will organize a telephone company.

Telephone Incorporations.

The Bondville Telephone Company, Bondville, Ill. Capital stock, $2,500. Incorporators: William H. Scott, George A. Keller and Otis W. Norton.

The Farnhamville Mutual Telephone Company, Farnhamville, Ia. Capital stock, $10.000. Incorporators: Charles Rose and others.

The Colebrook Telephone Company Colebrook, O. Capital stock, $3,000. Incorporators: V. G. Bedell, C. H. Turner, S. R. Cobb, J. L Allen, J. E. Diffon and S. L. Fobes.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Allentown, Pa.—A well organized movement is on foot here to establish a new electric light company.

Alpena, Mich.—The Alpena Power Company contemplates extensive improvements in the electric lighting plant.

Altoona, Pa.—The Citizens' Electric Light & Power Company will build a large number of extensions to its lines during the coming summer.

Amenia, N. Y.—The Morgan & Wyman Electric Light & Power Company, capitalized at $6,000, has been incorporated by C. B. Morgan, Cora Morgan, of this place, and C. S. Wyman, of Dover Plains.

Bartlett, Tex.—R. S. Decker has applied for a franchise to install an electric light plant here.

Colorado Springs, Col.—The corporation which recently consummated a deal for the purchase of the Seven Falls & South Cheyenne Canon for $225,000, has announced that, among improvements proposed at the Seven Falls, will be a colored electric illumination that will make its resort even more wonderful at night than it is in daylight. The illumination will be installed before June 1.

Columbus, O.—The Pan Handle Railroad Company, of this city, will expend $30,000 in improvements. An electric light plant will be erected by the company at Louisville, Ky.

Danville, Ky.—The Danville Light, Power & Traction Company, with a capital of $50,000, has been incorporated to light this city with electricity.

Fremont, Mich.—Claude T. Lloyd has bought the supply department of the municipal lighting plant here, and will carry a full line of electric supplies for the Western Michigan trade.

Grand Forks, N. D.—Bonds in the sum of $30,000 may be issued for the construction of a commercial electric light plant in this city. For further information address Mayor George F. Duis.

Green Bay, Wis.—The supervisors of Brown County are contemplating the erection of an electric lighting plant at the county farm.

Hope, Ind.—The Ryan Construction Company, of Indianapolis, has been awarded the contract to build and equip an electric light plant in this city.

Mason City, Ill.—The question of municipal ownership of the electric light plant here will be submitted to a vote of the people.

Muncie, Ind.—The Citizens' Electric Light Company, capitalized at $200,000, has been formed with the following directors: Charles E. Hinkley, H. J. Keller, W. G. Braun, C. Roy Hathaway and William F. Warner.

Newberry, S. C.—This city contemplates installing new machinery at its electric light plant, increasing the capacity.

Norfolk, Va.—The Norfolk & Western Railway Company will install a new system of electric lighting.

Ocala, Fla.—The Florida Power Company has been incorporated with a capital of $300,000, to construct and operate a waterworks and electric light plant. M. Camp is president.

Oregon City, Ore.—The Portland General Electric Company has applied to the city council for a franchise for the transmission of electric light and power.

Sioux City, Ia.—Samuel McRoberts and Edward Tilden propose to install an electric lighting system and a heat distributing system.

Starkville, Miss.—The citizens will vote April 15 on the issuance of $8,000 of bonds for improvements to the waterworks and electric light plant.

Williamsburg, Mass.—An attempt may be made to get an order through the city council authorizing the Williamsburg Electric Company to run its wires on to the village of Leeds, so that several streets can be supplied with incandescent lights

Woodbury, N. J.—The Gloucester County Electric Company, of this place, with a capital of $50,000, has been incorporated by Enos R. Artman, Manasses K. Twichler, Daniel G. Endy and others.

STREET RAILWAYS.

Bellefontaine, O.—The receivers of the Urbana, Bellefontaine & Northern Traction Company will improve the road at once and put it in good repair.

Buffalo, N Y.—It is predicted that within six months this city will be connected with Indianapolis by trolley.

Danbury, Conn.—It is reported that the Danbury and Harlem electric trolley railroad from this city to Golden Bridge, N. Y., will be built and put in operation this summer. The Philadelphia Industrial Company, it is said, is now backing the road.

Dayton, O.—The Dayton & Northwestern Railway Company, recently incorporated with $100,000 capital, will construct an electric line from this city to Kenton. Hugo Cook, M. W. Chambers and others, are interested.

Evansville, Ind.—Plans are under consideration by the owners of the Evansville & Princeton Electric Railroad Company to construct a system of interurban electric railways this summer.

Findley Lake, N. Y.—The Findley Lake & State Line Street Railway Company, of this place, has been formed to construct 13 miles of electric railway in Chautauqua County. Its capital is $130,000, and directors, F. R. Nichols, Titusville, Pa.; I. A. Pond, Corry, Pa.; E. A. Austin, Cutting.

Hanover, Pa.—Civil engineers are surveying for the proposed extension of a trolley line from here to Littlestown.

Independence, Kan.—W. H. Nees, general manager of the Union Traction Company, has stated that the interurban electric road will build to Neodesha.

Salt Lake City, Utah.—Simon Bamber has presented to the council an application for an electric railway franchise.

Utica, N. Y.—The Hudson River Electric Power Company will construct a power house here which will furnish power for the Utica & Mohawk Valley Railway Company.

POWER PLANTS.

Baring Cross, Ark.—It is reported that the St. Louis, Iron Mountain & Southern Railway Company will make extensive improvements here, including the remodeling of its power plant, etc. W. T. Tyler, of Little Rock, is general superintendent.

Corona, Cal.—An engineer of the General Electric Company, of Los Angeles, has lately been here investigating the possibilities of utilizing the water of Lake Elsinore for electric power purposes, the water to be brought in a high line to Temescal and there dropped into Temescal Cañon. The power generated in the canon, it is assumed, could be transmitted to various parts of the valley for street railway and electric lighting purposes.

Nashville, Tenn.—The Tennessee Power Company, with a capital of $100,000, has been incorporated by Cornelius Ackerman, William B. Dinsmore, Jr., and others, to manufacture electricity.

Raubsville, Pa.—The electric light and power plant of the Lehigh Power Company, located between the canal and the Delaware River just below here, has been purchased by B. F. Fackenthal and Lee S. Clymer, of Riegelsville.

Shoshone, Idaho.—The Shoshone Power Company has been organized with Francis M. Lyman, of Salt Lake City, as president.

BIDS WANTED.

Chicago, Ill.—The Ford Manufacturing Company, of 109 West Madison street, is in the market for two 100 hp. boilers for its Vandalia, Ill., plant.

Hot Springs, Ark.—N. M. Moody, of this city, wants prices on electrical equipment for a 4-story hotel.

Janesville, Wis.—Sealed bids will be received until April 24, for lighting this city with electricity for a term of five years. A certified check for $3,000 is required. Address A. E. Badger, city clerk.

Knoxville, Tenn.—Sealed proposals will be received until April 15 for furnishing lights, miscellaneous, etc., for this city during the fiscal year. Address W. L. Trent, custodian.

Luverne, Ala.—The Luverne Electric Light & Water Company wants prices on machinery and equipment for an electric light plant.

Michigan City, Ind.—The United States Brick Corporation, of this city, is in the market for a 150 hp. boiler and a 100 hp. engine.

Morton, Ill.—Beyer Brothers, owners of the electric light plant here, are in the market for one 150 kw. 220 volt second-hand generator, and one 16 x 27 x 16 Westinghouse compound engine in first-class condition.

Osborne, Kan.—This town is in the market for a 15 hp. engine, a 20 hp boiler, a 100 feet steel tower and an 80,000 gallon tank. Address J. A. Fouts, city clerk.

Raleigh, N. C.—The Elks Home Construction Company, care of L. A. Mahler, this city, wants prices on electrical equipment.

Washington, D. C.—The Bureau of Supplies and Accounts will rcceive sealed proposals until April 25 for furnishing the Mare Island and Puget Sound Navy Yards with the following: Schedule 134, conduit, wire, signal bells, switches, transformers, insulators, incandescent lamps, motors, fuses, sockets, cut-outs and other electrical supplies. Schedule 135, motors and chemicals for electrical use. Applications for proposals should designate by number the schedules desired. Blank proposals can be obtained at the Navy pay office in San Francisco, or at the Bureau in this city.

NOTES FCR INVESTORS.

Latest quotations for copper are: Electrolytic, 15⅛@15¼c.; Lake 15¼@15⅜c.; casting, 14⅞@15c.

The Toledo Railways & Light Company has declared an initial semi-annual dividend of 1 per cent., payable May 1.

The American Telephone & Telegraph Company has applied to the New York Stock Exchange to list $25,000,000 bonds.

The New Orleans Railways Company earnings now amount to about 5 per cent. on the new $10,000,000 of 5 per cent. preferred stock.

Industrial dividends in April will be the largest for this month in years. Declarations announced to date total about $24,000,000.

The New York & New Jersey Telephone directors have declared the regular quarterly dividend of 1½ per cent., payable April 15 to stockholders of record April 5.

A broker who claims to be well-informed as to the Philadelphia Electric-United Gas affairs is responsible for the statement that there is no deal between the two concerns.

An Albany, N. Y., dispatch states that before the final passage of the stock transfer bill it may be amended so as to make the tax $1 instead of $2 on each 100 shares sold or transferred.

The trustees of the Massachusetts Electric Companies have sold to Hayden, Stone & Co. $1,000,000 of Old Colony Street Railway and Boston & Northern Street Railway 50-year 4 per cent. bonds.

The sale of the Springfield (Mass.) Street Railway Company to the New York, New Haven & Hartford Railroad Company is not positively assured but present indications are favorable to the sale.

A special meeting of the stockholders of the Rochester (N. Y.) Street Railway Company will be held on Friday, April 7, to vote on the proposition to increase the capital stock of the company from $5,500,000 to $6,000,000 by the issue of 5,000 shares of preferred stock of the par value of $100 each. The stock will be offered pro rata to present stockholders at a price to be determined at the meeting.

The New York State Board of Tax Commissioners has increased the taxable valuation of the Brooklyn Rapid Transit Company $4,000,000 and the Metropolitan Street Railway Company an equal amount. The Manhattan elevated franchises sustain an increase of about $9,000,000, and the Subway franchises have been assessed for the first time at $9,000,000. The right to assess the Subway franchises is to be tested in the courts.

It is understood that the New York, New Haven & Hartford Railroad Company is a prospective purchaser of the Northampton & Amherst Street Railway, which was authorized Saturday morning to purchase on a share for share basis the Greenfield, Deerfield & Northampton and the Greenfield & Turner's Falls Street Railway Companies. The Northampton & Amherst Street Railway Company is authorized to issue 3,100 additional shares for purposes of exchange.

To learn what is invested in the gas business in New York is now the chief business of the Stevens Legislative Committee. As a result so far, Charles E. Hughes, chief counsel of the committee, arrived at about $27,000,000 as a fair valuation of the property. Surprise was occasioned by a statement that the Consolidated Gas Company, although it paid large dividends last year, actually had a deficit at the end of the year of $1,162,569.80.

EDITORIAL NOTES.

Private Plant and Central Station Lighting.

A large private plant represents the equivalent of a central station; and a small central station the equivalent of a private plant. These instances have presented themselves in the case of the recent St. Louis Fair on the one hand, and the lighting equipment of a large number of small towns on the other. Extensive territory occupied by large buildings and well lighted grounds calls for a well developed lighting plant. A plant of this character is simply an illustration of the natural growth of a private plant to fill the needs imposed upon it. It becomes large, complex and expensive, but retains in every respect the fundamental elements which originally constituted it. A private plant thus becomes private only because its lighting is done for a relatively limited community. It need not be a small community, but its lighting must be of such a character that the machinery and devices required bring it into the classification of central stations. This brings forward the point of interest—the fact, that the scope of the lighting done by a central station makes it such—it is the lighting which makes the station, not the station the lighting. This distinguishing feature clearly shows that large plants or central stations are rarely if ever erected unless either contracts for current have been closed or subscriptions to that effect are in the possession of the promoters of the enterprise. The outlay for boilers, engines and generators is an expense which does not demand a very heavy premium for their continued support and operation. In other words, the largest of generators and engines do not require a better man than those of half the size. In fact, it is surprising to realize how few hands are necessary to attend to the running of the largest of central stations. A private plant represents no departure in this respect.

The cost of its operation is proportionately higher as compared with its output than that of a central station. Increase its size, however, and it rapidly merges into the latter type. These considerations throw some light on the question of expense of operation and the legitimate charge for current in the case of electric light companies. The greatest outlay of such concerns is not the station or the real estate, but the underground equipment. If the wires are strung overhead, the expense still stands. All the wit and ingenuity of experts is tried to its utmost in the effort to limit the cost of the wasted power in the circuits and still not invite unusual expense in the design of these circuits. The financial load of central stations, with a vast network of copper mains and feeders demanding an annual interest payment, and a large bill for wasted energy in these conductors, is bound to be very great even with a large circle of customers. The law enunciated by Lord Kelvin, "That the interest on the cost of the copper conductors should not exceed the cost of the power wasted in them," was a guide in the early days, when simple systems were in vogue. It is only a hint of the expense sustained to-day. But with all that, the large private plant is not a loss to its operators, if intelligence is displayed in its equipment, and the care it requires. Private plants and the cost of their lighting have been compared with the cost of an equal amount of lighting by central station on numerous occasions. The result has not always been satisfactory to either. Many large establishments have taken out their systems and depend entirely upon the street service. To negative this, evidence can be produced to show that many have installed private plants to avoid this necessity and in some cases only to become independent of what they call "the lighting monopoly." As far as this latter is concerned, it is quite evident that the destruction of competition in the lighting field gave rise to it. It has borne its own evils, and they in return react with all the bitterness and contempt of an aroused public opinion. It is to be admitted that electric lighting is an expense, but why an unusual one is beyond comprehension.

From a general standpoint, it seems that the enormous increase in business which lower rates would induce, is in itself a guarantee of the shortsightedness of any other policy. Yet, while the haberdasher, the dairyman or the baker, may make undisturbed whatever profit they see fit to demand, it hardly seems fair because a franchise has concentrated public attention upon what is regarded as a public necessity, that the one can go its way in peace and the other be haled to the bar of justice. Large business interests may not be so hurried in their cooperation and consolidation in the future. The public can cope easier with the giant than with any of his limbs. The lighting corporation represents a totality of interests, that can best continue on a useful and profitable career by agreeing to the popular demand. By this means the increasing application of electrical energy would mean a widespread benefaction to the poor as well as to the prosperous.

* * *

The Result of Chicago's Election.

As expected, Judge Edward F. Dunne defeated John Maynard Harlan for Mayor of Chicago in the recent election. The question at issue was municipal ownership, but holders of traction stocks are not alarmed over the result. These are the steps by which Mayor Dunne—who assumed the duties of his office on Monday—expects to bring about what he was elected for:

"By the appointment of a commission of street railway experts and eminent lawyers, placing at their head a big man worth a big salary—a $50,000 man in merit, if not in price—and raising the money to pay him by public subscription, if need be. By requiring this commission to consider the situation, the value and utility of all present street car properties and to arrive at a conclusion for general action, no radical move to be taken prior to the decision of this body. By making, while these larger plans are in process of evolution, a direct experiment with the line upon which the franchise already has expired, securing the right to operate by moving Judge Grosscup to release the line from the injunction proceedings which now tie it up. By prosecuting what court actions his corporation counsel and other advisers decide will fit into the grand scheme."

From a survey of the new city council membership as regards probable action on municipal ownership of street railroads, friends of the corporations assert that they are not fearful of the results of any legislation that may come before the councilmanic body. In fact, it is asserted, in some quarters, the council will be a safe neutralizing agent, as practically the same men who were in control of the last council will retain control of the next one.

As the Illinois Legislature will soon adjourn for two years, during the term of Judge Dunne as Mayor no State legislation can be enacted to enable Chicago to increase its public debt, for the purpose of purchasing the street railroads of Chicago, or for any other purpose.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

It is reported that the daily output in Germany of the tantalum lamp, which will shortly reach an average of about 5,000 a day, is sold as fast as produced.

The Magnetic Club of New York will hold its spring meeting and dinner at the Hotel Astor Thursday, April 13.

It is announced that the Legislative light inquiry in New York will be finished this week and that the committee will present bills for enactment reducing materially the legal limit of charges for gas and electricity.

Mr. Frank W. Frueauff of Denver, when in New York last week, stated that the railroad people had been making an extensive canvass among possible delegates for the Denver-Colorado Springs convention of the National Electric Light Association. They report their belief that there will be an attendance of at least 3,500. This may be a little optimistic, but there is no question that the meeting will break all previous records in point of attendance as well as in point of general attractiveness.

The "Journal" of the Chemical Society contains an abstract of an article by Mr. R. Ditmar on the action of radium rays on caoutchouc. The power of radium rays of penetrating caoutchouc has been examined by Madame Curie's radiographic method. A "concentrated" preparation of de Haen's radium barium bromide was used, but the action of this substance was not sufficiently powerful to induce radioactivity in the caoutchouc itself. The following conclusions, says the "Electrical Engineer," London, have been derived from the results of the experiments of the author and the investigations of Madame Curie. The radium rays penetrate both crude and vulcanized rubber, but the former more readily than the latter, probably owing to its porosity. Caoutchouc itself may be rendered radioactive (Madame Curie). The loss of activity of caoutchouc in air does not take place in accordance with the law which usually obtains for solids.

The New York Electrical Show managers are taking time by the forelock and announce that the exhibition will be held at Madison Square Garden December 12 and 13. Prof. G. F. Sever is director of exhibits.

Wireless telegraph experiments with trains will be tried at Purdue University in Lafayette, Ind. The electrical engineering building commands a view of long stretches of the Monon, Wabash, Big Four and other railroads, and instruments will be placed on various trains for testing purposes. It is believed by Prof. Kelsey of Purdue that difficulties encountered in previous tests have been overcome. It is the intention of the university to conduct a series of tests to the end that a receiver may be placed in the cab of the engine, within reach of the engineer, from which he may take his running orders from the dispatcher without stopping his train.

Mr. LaRue Vredenburgh, who so ably handled the subject of advertising in his report presented at the Boston convention of the National Electric Light Association, will this year make a report on "The Commercial Side of Sign and Decorative Lighting," which will be presented at the Denver-Colorado Springs convention. This is a subject of great interest to all the members of the association, and Mr. Vredenburgh's skill and experience will enable him to handle it in a most satisfactory and interesting manner.

A meeting of the National Conference on Standard Electrical Rules will be held at 10 A.M., Friday, April 21, at 55 Kilby street, Boston. The American Institute of Electrical Engineers will send an official delegate and will also be represented at the sessions of the Conference by its Committee on National Electrical Code.

HIGH POTENTIAL APPARATUS FOR WIRELESS TELEGRAPHY.

BY A. FREDERICK COLLINS.

The development of the alternating current transformer has been due to the extension of the single-phase current, but the induction coil owes its present state of perfection to the discovery of the X-rays and the advent of wireless telegraphy.

While both the induction coil and transformer utilize the same principles of mutual induction the fine distinction between them lies in the fact that the former is energized by a direct current from a suitable source of electromotive force and converts this into an alternating current by means of an automatic make-and-break, while the latter transforms an alternating current into one of higher or lower potential, as the case may be.

At the present writing both of these devices are employed extensively in wireless telegraph practice, but there are several other arrangements by which the high potentials necessary for producing a disruptive discharge of sufficient intensity to set up oscillatory currents may be obtained. For instance, we may cite the frictional and static induction machine, the Elihu Thomson condenser apparatus, and recently James Foster King has proposed an ingenious method for raising the pressure of a direct current by self-induction until a sparking potential results.

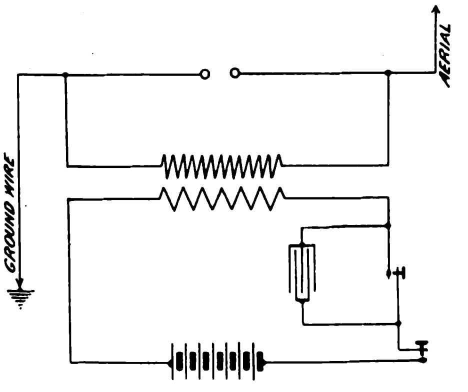

Fig. 1.
Induction Coil Transmitter.

In wireless telegraphy it is of prime importance to have a large current strength as well as a high tension, in fact the working pressure is usually little more than that of long distance transmission lines, say from 20,000 to 50,000 volts. In the glass-plate machine these conditions do not prevail, for the pressures are enormously high and the current values infinitely small, hence this type of apparatus has found little application in experimental wireless transmission and none at all in commercial work.

The induction coil with its record of over half a century as a producer of electric sparks was the first of the devices used for the purpose under consideration. It consists essentially of a long, straight soft iron core, a primary winding called an inductor, the terminals of which are connected with a battery or other generator, and an automatic interrupter; shunted around this make-and-break device is a condenser, and the whole schematic arrangement is indicated in Fig. 1. Outside the inductor is wound the secondary coil, the terminals ending in brass spheres which form the electrodes of the spark-gap.

The inductor of a primary coil is most efficient when it is formed of two layers, and the wire should be of large cross-section so that the losses due to heating may be reduced to a minimum, but if too large the inductance will tend to produce excessive sparking at the interrupter contacts. To overcome this objectionable feature a number of small wires, equal in conductivity to a single large one, may be used to advantage.

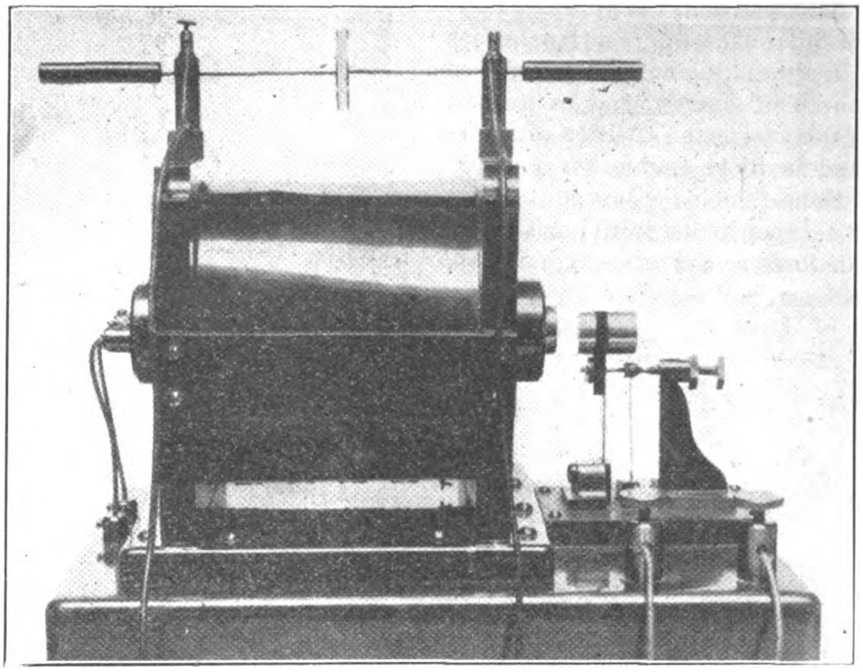

Fig. 2.—Induction Coil.

The wire used in winding the secondary for a wireless telegraph coil should be at least 50 per cent. greater in cross-sectional area than that intended for X-ray and general laboratory work, thick and short rather than attenuated, and long discharges are required. Now, as the ratio of transformation is directly proportional to the number of turns of wire forming the secondary and primary, the output at the terminals of the latter will be equal to that of the initial energy except for a small loss in transformation and a large waste that takes place on the breaking of the circuit by the interrupter.

The insulation of induction coils is of great importance, for unless great care is exercised in this detail of construction electrostatic stresses are set up between the successive disks making up the secondary, and these have a tendency to strain the insulation, especially if air bubbles have been formed, in which case the coil may be disrupted at any time. In building large coils it is the practice of makers to pass the silk or cotton-covered wire through a compound of melted resin and beeswax in winding the disks, and then after these are connected together they are placed in vessel of the same ingredients while in a fluid state and under the receiver of an air pump the air is thoroughly exhausted, and in this way a vacuum secondary is formed.

The vibrating make-and-break is the most familiar type of interrupter used, but the mercury turbine and electrolytic interrupters are much used in connection with coils designed for wireless transmission, and especially is this true of those of foreign construction. The break should be as nearly instantaneous as possible, and the more nearly this ideal is approximated the smaller may be the capacity used.

The function of the condenser, which is shunted around the interrupter, is to prevent excessive sparking at the contacts when the circuit is broken. With electrolytic interrupters no condenser is required, for the breaks take place at the rate of 10,000 per minute, and this gives the inductance of the primary current but little time to rise to a potential where it is accentuated, and further, an electrolytic interrupter possesses a certain inherent capacity of its own which entirely eliminates any untoward effect that might otherwise result.

The chief advantage the alternating current transformer has over an induction coil for the conversion of low voltage currents into effective disruptive discharges for the production of electric waves is that the uncertainties of the interrupter are entirely done away with, while in large units it becomes possible to take care of a greater amount of energy than where the cycle of operation requires an absolute break. Again, a transformer may be constructed with mathematical precision, which is practically impossible with an induction coil.

On the other hand, where a transformer is used an alternating current is required as a source of energy, and in isolated stations this means the addition of a generator and finally an engine for its operation. Hence the induction coil system is much cheaper in its initial cost than the transformer and its auxiliary appliances.

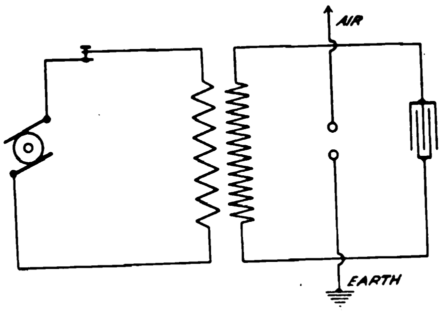

FIG. 3.
Transformer Transmitter.

In the alternating current transformer the generator is connected in series with the primary of a transformer; the terminals of the secondary are connected in series with a number of Leyden jars, and a spark-gap is usually shunted across the terminals, as shown in Fig. 3. When the jars are charged to their maximum capacity they break down the insulating film of air forming the spark-gap and a disruptive discharge of great intensity takes place. This is the type of oscillating current generators that have been installed by Marconi at the Poldhu, Glace Bay and South Wellfleet transatlantic cableless stations.

While the construction of transformers are more or less well known a few words concerning their manufacture for wireless telegraph purposes may be of some value. The transformer usually employed is known as the core-type, that is, a core made of sheet iron stampings in the form of a rectangle frame, and forming a complete magnetic circuit takes the place of the straight iron core in the ordinary type of induction coil. Over the limbs of the core the primary and secondary coils are slipped into position. The primaries of each coil may be connected in series or in parallel in order to obtain the proper value of voltage in the primaries; the secondaries are usually connected in parallel, the terminals leading to the electrodes of the spark-gap. Coils of this construction are placed in either iron or wooden cases and these may be filled with oil or insulated with solid asphalt.

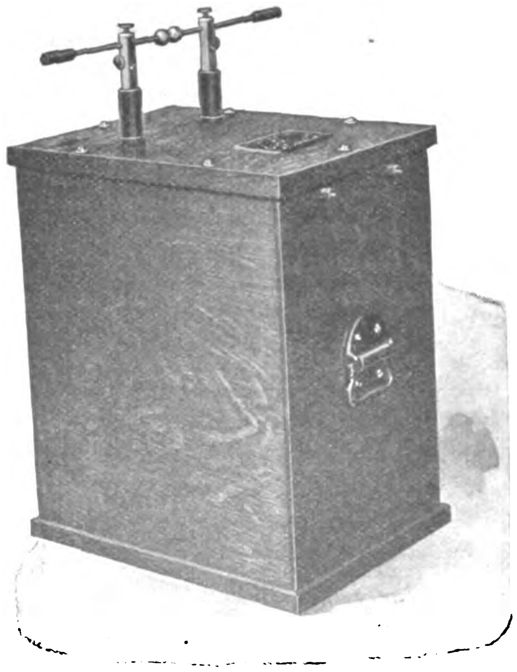

FIG. 4.
High Potential Transformer.

A recent device designed by Prof. Elihu Thomson for producing heavy disruptive discharges is shown in Fig. 5. It comprises a small rotary converter which is operated by a direct current, and through slip-rings and taps single phase currents may be taken off. This portion of the apparatus is contained in the lower part of the wooden case, the latter also including a transformer for stepping up the low voltage current to one of 20,000 volts.

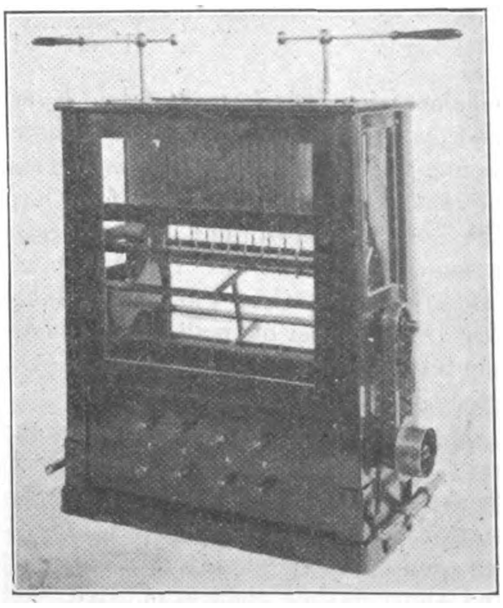

FIG. 5.
Prof. Elihu Thomson's High Potential Generator.

The latter are connected to two arc-shaped pieces which are insulated from each other and do not form contact with, but come very closely to, projections on the revolving frame below. On one side of these arc-shaped pieces are a similar set arranged in two series, corresponding to the two terminal pieces and leading from them to a set of glass condensers. When the high potential terminals make connection through the revolving frame with the condensers they are charged in parallel, as though they formed one large condenser, but when the frame is partially revolved again they are connected in series, so that their individual potentials are added together, and in this position they discharge through the spark-gap, when, assuming that there are ten condensers, the effective potential would now be 200,000 volts.

This apparatus is a very effective high potential generator, and as it is portable is not affected by the weather and its potential may be easily regulated; it should prove of great value as a converter of low voltage currents into high oscillations, such as are required for long distance wireless telegraph transmission.

ELECTRICITY LEAFLETS.

BY NEWTON HARRISON, E. E.

THE TELEPHONE.

The Transmission of Speech.—To transmit speech by electricity is one of the most interesting exhibitions of the law of the conservation of energy. To speak is to produce a series of vibrations in the vocal chords, the effect of which is to create air waves or sound waves. The exact nature of this process in a human being belongs to the department of physiology, but the influence and effect of these sound waves upon the telephone, the means by which they are transmitted and again distributed falls distinctly within the province of electricity.

The act of telephoning therefore consists of three processes, each of which contributes to the general result in a manner exhibiting an indispensable relationship. They are as follows:

First—Sending or directing the voice into a transmitter.

Second—Conducting the voice equivalent over a line.

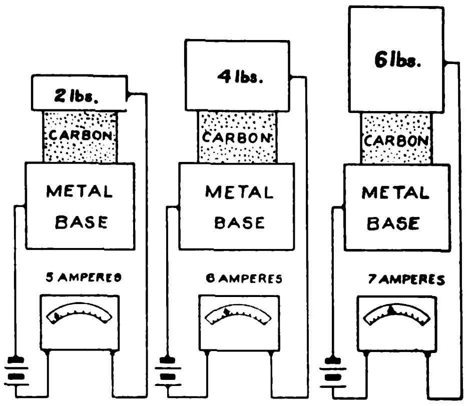
Third—Receiving the voice equivalent at the end of the line.

These elementary processes necessarily call for devices suitable for the purpose in view and, in consequence, the process itself has been the means, in each individual case, of giving a name to the apparatus.

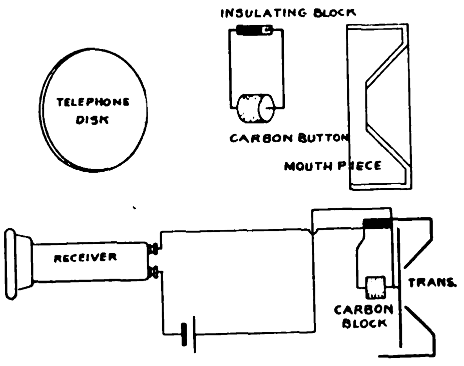
The sending instrument is called the transmitter, the conducting circuit the line, the instrument which conveys the sound to the ear the receiver. It must not be understood from this that any *sound* is either transmitted, conducted or received. The phenomena are all electrical and magnetic in the strictest and fullest sense of the word, with two exceptions; these are the instances where the human voice enters the transmitting device and where, when *its electrical equivalent* operates upon the receiver, it is transformed into the more or less familiar tones of ordinary speech.

Historical.—The invention of the telephone is generally credited to Dr. Alexander Graham Bell, and justly so from a broad legal and scientific standpoint. Other workers in the same field were Dr. Elisha Gray and Reis, but their efforts were not of a sufficiently practical nature to entitle them to the credit of the present device, which is not the transmitter but the telephone receiver. Although transmitting and receiving instruments in practice are entirely different in their principle and construction, one being purely electrical and the other purely electro-magnetic, yet both the transmitting and receiving of speech was successful over short distances with but one instrument, the receiver, on which was based one of the most successful and indispensable electrical systems ever evolved for general use.

The Telephone Transmitter.—The nature of the device used for transmitting speech is based upon the requirements of an acoustic electric system. The general idea underlying all the operations is that of receiving the air vibrations, reproducing them as far as possible in the form of electricity, sending them over the wire as a set of electric undulations and finally turning the electric undulations into sound waves by means of the telephone receiver. The theory upon which the transmitter operates is that of the effect of mechanical pressure upon a small block of carbon. The mechanical pressure is obtained by means of a thin sheet of iron called a diaphragm, which is so mounted as to delicately and irregularly compress a carbon button at its center. The diaphragm is of the thickness of ferrotype iron (photographic iron) and when the human voice is so concentrated by means of an appropriate mouthpiece to play upon it, the air vibrations or air waves beat upon the diaphragm with varying degrees of pressure which, being conveyed to the carbon button, compress it with great rapidity to an infinitesimal degree each instant. If a current of electricity is allowed to flow through the carbon button, which under ordinary conditions is uniform in strength, it is evident that when the carbon button is being thus affected, by the varying degrees of pressure, the current will also be affected if it can be shown that *the conducting power of the carbon* is continually changing. This is the case in point; the resistance or the carbon changes with each variation in the mechanical pressure caused by the voice waves. These changes are the cause of corresponding waves or undulations in the current, and their detection is best accomplished by means of the receiver. In other words, the transmitter is a device in which the human voice causes a carbon button to increase and decrease in resistance, and a uniform current passing through this button at the time will have its strength increased to an infinitesimal extent when the diaphragm presses against it due to the impact of an air wave. A current is therefore always passing through the transmitter when it is in use; and its delicacy and faithfulness in reproducing the air waves impinging upon it, in the form of electrical undulations, depends upon the adjustment between the diaphragm and carbon button.

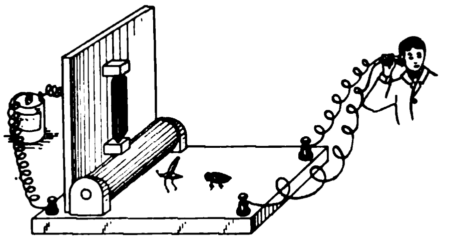


Effects of Mechanical Pressure on Carbon in Reducing its Resistance.



Elements of a Transmitter.

The Microphone and Carbon Button Transmitter.—The introduction of the carbon transmitter by Emile Berliner, Blake and Edison was the means of relegating the original Bell telephone to the function of a receiver. It is in this respect, which is as a detector of minute variations in current, that the receiver best serves its function. Long distance telephoning would be impossible without the transmitter, which in its present form is only an adaptation of the original microphone of Hughes. The idea he had in mind was to invent a phonendoscope, by means of which the respiratory organs could be tested The extreme delicacy of the microphone and the need of preserving the original sounds of breathing and of the heart beats caused his suggestion and device to fail in this respect, although otherwise recognized as a most remarkable invention. A microphone is in reality a "sound microscope." It will develop or augment delicate sounds to such an extent that in a well constructed device of this character the walk of a fly, the human breath or the merest scratch are magnified to enormous proportions. The device consists of a sounding board on which is mounted two carbons in delicate adjustment with respect to each other and in circuit with a battery and telephone receiver. Depending upon the adjustment, as previously stated, the carbons will, under the influence of the faintest vibrations, cause minute changes in current strength, due to varying degrees of pressure of one carbon upon another, and thus develop sound in the receiver. The carbons are therefore governed as far as their operation is concerned by



A Microphone in Service with a Receiver.

First—The adjustment in a mechanical sense.

Second—The fineness of quality of the carbon.

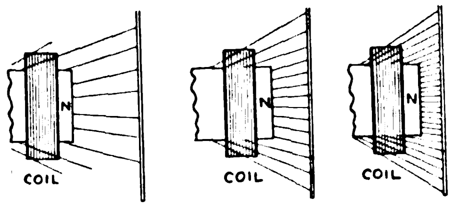
Third—Uniformity of the current.

Transmitters for telephonic purposes are made with reference to the service they are to perform; to transmit the voice with all of its characteristics, as far as science will allow. They are made in two forms, either with a hard carbon button, or in particular cases where extreme delicacy is required, with a tube of granular or powdered carbon with a plug of carbon at each end. It is but reasonable to infer from the preceding that great delicacy of action can only be obtained through the medium of the carbon, and it therefore follows that the texture of the carbon, either as a granulated mass or in the solid form, must receive the closest of attention in the construction of transmitters for local and long distance service.

Fundamental Tones and Overtones.—That which is called timbre is the characteristic of any musical sound. It is the distinguishing feature between the same note of a piano and a violin. The investigations of Helmholtz clearly proved that this characteristic difference was due to the presence of overtones. By this is meant that when a string is set into vibration, it not only produces a sound at the expected rate of a certain number of waves per second, but in addition a host of smaller secondary waves which enrich the tone and establish its character. The human voice is no exception to this, as its fundamental tones are aided by a series of overtones, the variety and quality of which must be preserved in telephonic transmission as far as possible, if the identity of the owner is to be readily recognized. The fundamental tones are more easily transmitted than the overtones, due to the effect of inductive influences in the line; but retardation occurs with respect to the others, depreciating the transmission to a serious extent. The transmitter must pass these tones, transformed into alternating current waves in the line and receiver as completely as the device will permit. Adjustment thus becomes a fine art, and is conducted with reference to the average clearness and loudness obtainable. This is exemplified in the case of a man and a woman's voice reaching over the line with almost equal distinctness, which is a matter of little or no comment in local lines, though a matter of great surprise in thousand mile circuits.

The Receiver.—The receiver was first exhibited publicly at the Centennial Exposition at Philadelphia in 1876 by Dr. Bell. This instrument, with which speech can be both transmitted and received acts as a transmitter entirely by electro-magnetic induction. The principle of its operation is identical with that which serves to underlie the construction of all generators of electricity. In other words, the receiver is essentially a dynamo, generating minute alternating currents, which serve to excite corresponding vibrations in another receiver. The fundamental idea predominating in the case of a receiver is that of the variation in the number of magnetic lines of force passing through the coil of the receiver. That which is so called consists of three parts as follows:

The magnetized steel bar.
The coil of fine wire.
The diaphragm of iron.

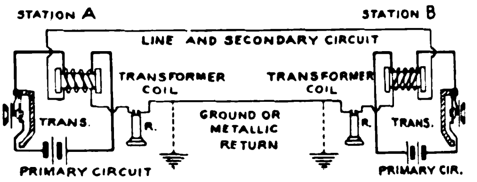


Distribution of the lines of force at the end of a telephone receiver when the diaphragm is far away, nearer and at a normal distance. More lines pass through the coil in each case.

The magnetized steel bar is fitted with a small coil of fine wire at the end nearest to the diaphragm. This coil of wire is placed on the end of the magnet, and is made of many turns, so as to be sensitive to the slightest change in the number of lines of force entering it. The elements of a dynamo thus appear: the source of magnetic energy, the coil or inductors affected by the magnetism, and the energy generally throwing these elements into co-operation. In this case, the mechanical energy of the voice is absorbed in setting the disk of iron into vibration. In this particular respect, the vibration of the diaphragm and its relation to the magnetic field radiated from the magnetic poles is entirely a matter of leakage. By this is meant, that in general the fact of moving a piece of soft iron in the vicinity of a magnetized body, is to disturb the arrangement of the lines of force of that body. Those that have been radiating freely into the air will now, to some extent, pass into the mass of iron in their neighborhood. The near presence of a thin plate of soft iron at the end of a permanent magnet means a certain arrangement and position of the lines of force at that end. The least movement of the iron and the lines of force will slightly change position. In other words, the nearer the iron is moved to the end of the magnet, the thicker they will cluster around the iron, and in doing so the greater the number that will now thread the coil. The vibration of the diaphragm is thus the means of moving an iron mass nearer and further away from a magnetized body. In this manner the lines of force entering the coil are constantly varying in number, with the result that exceedingly delicate alternating currents are produced as the equivalent of the extent of the variation in the lines of force in the coil, or primarily as the result of the impact of air waves caused by the human voice. Currents like these, received in a similar instrument will, when they pass, move the iron diaphragm back and forth with each complete alternation. The effect of this is a duplication of the sounds of speech.

The transformation is, therefore, exactly the same as that transpiring in an electric power transmission plant. First, the absorption of mechanical energy and its transformation into electricity; second, its conduction to another point, and finally its retransformation into mechanical energy again.

A Simple Station System.—To raise the pressure of the current issuing from the transmitter, use is made of a coil of two windings. This miniature transformer receives the current of the battery, which passes through the carbon contacts of the transmitter, in its heavier winding or primary coil. The coil of fine wire forms another circuit, distinct from the first, in conjunction with the outside line and the two receivers. In the illustration one-half of the line is shown as either metallic or grounded, This is accomplished by means of gas pipes or a sunken metal plate at each end. The battery circuits are purely local at each end, operating with entire independence. The battery must receive attention if its strength diminishes, though this has been replaced in city equipments, particularly New York, by an independent current line, the power being generated in small dynamos and distributed for the same purpose.



Simple Two-Station Telephone System.

The points of contiguity between the three circuits are only two, and occur at either end where the transforming coil is found. Thus the system in its simplest form consists of the following:

First—The primary circuit at one station.

Second—The secondary circuit including the line.

Third—The primary circuit at the second station.

The transforming coil is actuated entirely by electro-magnetic induction as well as the receivers; the system therefore appears as one in which the transmitting devices operate through slight variations in the resistance of carbon buttons and the transformation, conductance and receiving through slight variations in magnetic fields.

The Peruvian Corporation is planning to build an electric railway to connect the city of La Paz, Bolivia, S. A., with the Peruvian Railway, which has its terminus at Lake Titicaca.

THE FUTURE OF THE ELECTRIC AUTOMOBILE.*

BY T. G. CHAMBERS.

In dealing with the future of the electric automobile it is impossible to foresee what developments may take place. The discovery of some new accumulator of small weight and of great capacity, with phenomenal endurance would, of course, alter existing conditions; but it is far more probable that nothing of the kind will be found, and that we shall continue to use the same materials that we have today with all their drawbacks. I propose to consider the commercial future of the electric carriage in its present form. Here we have certain reliable data upon which to base conclusions. We are aware of the requirements in certain directions, and we know the economical and practical advantages, as well as the limitations, of the electric carriage. The elasticity of the electric motor and its ease of control, together with silence and absence of smell and vibration, made the electric carriage very attractive at an early date. The inherent disavantages of the dead load of accumulators and the necessary limit to the available supply of energy which could be carried, were not so apparent in the days when automobiles of all descriptions were of comparatively slow speed, and when a day's journey of 100 miles without a hitch was a rare occurrence. Experiments with carriages propelled by the power available from primary cells carried in the vehicle date from 1832, but it was not until the year 1881 that a carriage was designed to carry secondary batteries. The modern electric car has been developed during the 24 years that have elapsed since that date.

The electric carriage is as nearly proof against mishap as any machine can be. Taking the last six months' working of the Electromobile Company's Curzon street garage, I find the total involuntary stops, excepting those due to power exhaustion, to have been 61 in 159,258 carriage-miles. Of these stops 14 were due to a mechanical defect in the contact breaker, the possibility of which has since been entirely eliminated by an improved mechanism; nine were due to tire troubles; 13 were due to the blowing of the main fuse, a matter immediately repairable by the driver. This leaves only about 25 stops in about 160,000 carriage-miles necessitating the attention of a mechanic, or on an average one stop in every 6,400 miles. When it is remembered that at least half these carriages are in the hands of comparatively raw drivers, and practically all of them are in the hands of men without mechanical training, the reliability may be considered very great indeed.

When the limitations of the accumulators are understood and recognized little or no difficulty arises from power exhaustion. With an effective range of from 25 to 35 miles upon one charge, and with the adoption of interchangeable batteries, a carriage may be run all day, if only time be allowed for its return to a depot to take up a new battery, an operation which takes from two to three minutes. The far-reaching importance of this system of rapidly exchanging an exhausted battery for a fully-charged one cannot be too much insisted upon. It will probably have a material effect upon the future of the electric carriage.

Even with a garage in the most expensive and central position of London the total costs per year are considerably less than they would be in the case of a horse-drawn carriage giving a similar degree of luxury. When the electric carriage is used to its full extent the costs are very considerably less. In certain individual cases I might name, owners have effected an economy of as much as from $1,000 to $1,500 a year by exchanging their horse carriages for electric vehicles, and in no case am I aware that they are spending more than they did with their horses. As compared with other types of automobile, I am of opinion that on the absolute bedrock of cost per carriage-mile under similar conditions the electromobile will show an advantage.

Accumulator renewals have been reduced by organization and careful treatment to a figure equal to, if not below, that of the cost of tire renewals, and in other respects the mileage costs of the electromobile will compare favorably.

With regard to future cost one may confidently predict that the tendency will be downwards as regards both power and battery renewals. At the present time the most favorable contracts that can be obtained in London for power supply do not bring the cost per Board of Trade unit below 3 cents. There is no reason why this should not be reduced to 1 cent. The cost of renewals of battery plates will be very largely reduced as the output of plates is increased by the demands of the growing business. This will be more marked if an agreement as to the use of a standard plate can be come to by the principal makers of electric vehicles.

We may now turn to the main object of this paper, the consideration of the commercial future of the electric carriage. Dealing first with the touring car, I will at once suggest that the electric carriage will not be the touring car of the future. Nothing short of the discovery of some new element will provide us with a battery that will give us the electric touring car. The lead accumulator will not give it to us, even if improved 50 per cent. and if the country be studded with charging stations. I do not think the nickel battery will give it to us, whatever may be its possible practical and commercial advantages in other directions. The electric car with a featherweight battery would still have certain disadvantages as compared with the explosion-engine carriage. The charging station would have to be reached, and there would remain the risk of battery exhaustion through accidental increase of power consumption on account of bad roads, hilly country, faulty lubrication, and a hundred other causes.

Turning to commercial vehicles, the question of the required range of action is the dominant factor. Given a limited distance and suitable roads, I see no reason why the electric carriage should not have a very considerable future in this field, nor why the light delivery van for town use should not be accumulator driven. Here the conditions are very suitable. Ability to start at once, noiselessness, reliability in the hands of an unskilled driver, the small amount of overhauling required, and the moderate amortization fund necessary for renewals, are all arguments in favor of the electric carriage. The light electric delivery van is already a success in other countries. With regard to price, the time is not far distant when such a van can be sold at a very moderate price, say from $1,500 to $1,750, without tires or batteries, and the tendency will probably be towards the sale of such carriages outright to users, the sale being coupled with a contract for maintenance together with the use of tires and batteries upon loan; such a system will appeal to the user, as the capital outlay will be small, and he will have the security of the maintenance contract against unknown expenditure on upkeep.

The omnibus of the future will not, in my opinion, be electrically driven. The conditions are by no means those in which the accumulator car is likely to be successful. The constant and erratic stopping and starting, often upon hills, and the heavy weight of body and passengers, are quite against it. If the accumulator passenger tramcar running upon rails has been unsuccessful in the past, it is only reasonable to conclude, having regard to the expense of tires and the increased consumption of energy, that it will be even less successful on the common roads.

---

*Abstract of paper presented at a meeting of the Automobile Club, London, Eng., March 16, 1905.

The hackney cab constitutes another very difficult problem, and I think it will still be a long time before any self-propelled carriage will be commercially successful in this field. Any discussion on this subject is bound to center itself on the question of costs, and I do not believe that sufficient experience has been gained in the practical operation of automobile cabs for a sound opinion to be forthcoming. Town ambulance work is so essentially the province of the electric car that I may be forgiven the mention of such a limited field. In this case every advantage of the electric carriage plays an important part, while its disadvantages have little or no effect. The only necessity is a proper organization to deal with the carriages, and this may already be said to exist in its best form in connection with the fire brigades, which have reached such a high pitch of excellence in most of our cities. There would be no difficulty in rendering every fireman and every police constable an efficient driver.

It is unnecessary to say much with regard to the automobile of the future which is to take the place of the smart horse-drawn carriage. In my opinion this will, without doubt, remain electrically driven. It is probable that in cases where only one carriage can be afforded, the petroleum car will always be in demand; but when two automobiles can be kept, it is more than probable that the electric carriage will be universally adopted for purely town use. The petroleum car is not likely to become the carriage for shopping, calling, theater or night use.

There remains to be considered one very important field of the future. What automobile is to take the place of the single-horse brougham? The average medical man cannot afford to pay more than $1,250 or $1,500 a year for the use of a carriage, including the driver. I do not think that any automobile which the smart doctor leaves standing outside the doors of his fashionable patients could be let out to him at less than $1,625 a year. Is this a prohibitive figure, considering the advantages which a business man would receive by the increased speed of his carriage, and, as a consequence, the larger amount of time he could give to his professional work?

Dr. Lee De Forest, inventor and at the head of the American De Forest Wireless Telegraph Company, is in Havana, Cuba, installing stations.

PROVIDING FOR INCREASE OF POWER IN ISOLATED STATIONS.

ARTICLE IV.

BY W. H. WAKEMAN.

Calculations to demonstrate the increase in power secured by plans given in the preceding article will prove interesting to engineers. As we assume that an economical load is to be carried in both cases, the terminal pressure will be about 5 pounds above atmospheric pressure, which is assumed to be 15 pounds. This makes the terminal pressure about 20 pounds more or less according to conditions. Clearance will not be included in these approximate calculations.

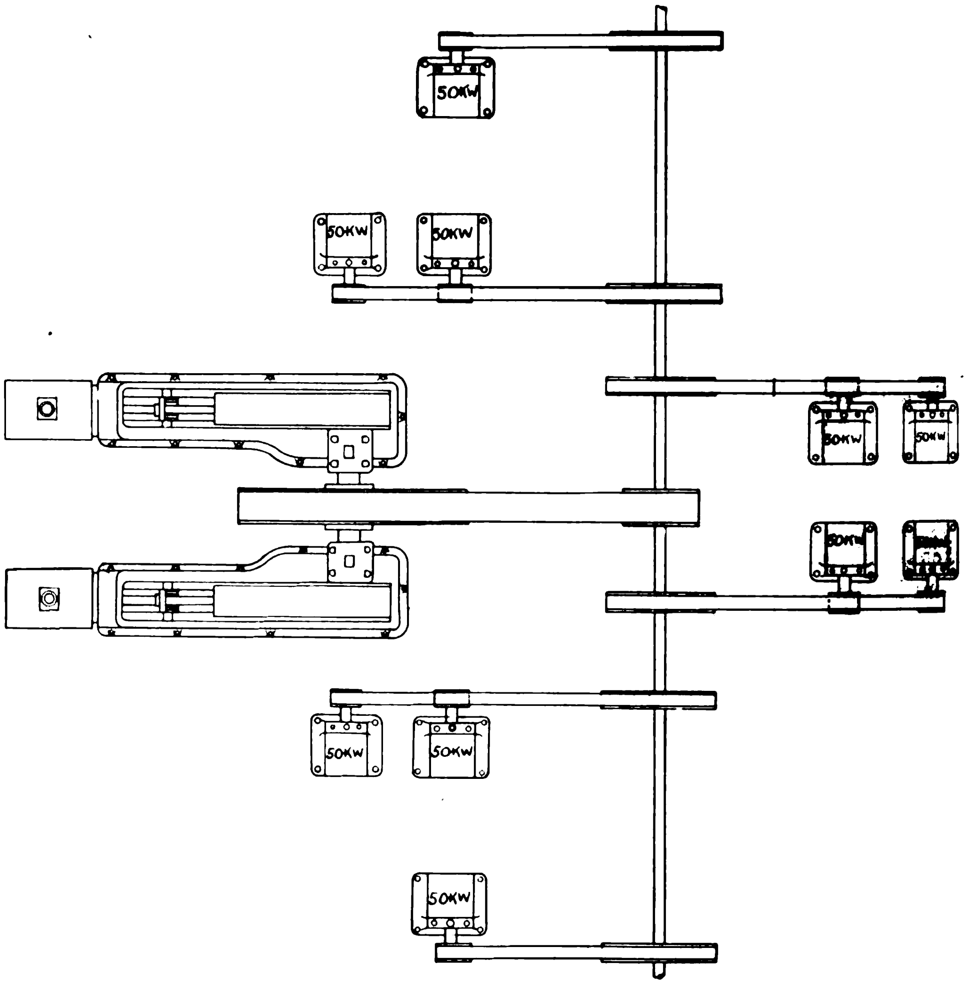

Fig. 5.

With a gauge pressure of 75 pounds the initial pressure should be 70 under fair conditions, or 85 pounds absolute. As the ratio of expansion is found by dividing the initial by the terminal pressure, in this case it is 85 ÷ 20 = 4.25. As we now have the initial pressure and the rate of expansion the mean effective pressure may be found by the following formula:

$$\frac{H + 1 \times P}{R} - B = M.E.P.$$

H = hyperbolic logarithm of ratio of expansion.
P = initial pressure absolute.
R = ratio of expansion.
B = back pressure absolute.
M.E.P. = mean effective pressure.

Assuming that there is no back pressure above the atmosphere, and applying the formula to the conditions mentioned, results as follows:

$$\frac{1.4469 + 1 \times 85}{4.25} - 15 = 33.94 \text{ pounds}$$

mean effective pressure.

The area of a 20 inch piston is 314 square inches, and at 70 revolutions the piston speed is 490 feet. The result is that

$$\frac{314 \times 33.94 \times 490}{33{,}000} = 158 \text{ hp. developed.}$$

Raising the boiler pressure to 110 pounds by the gauge gives 125 pounds absolute, and allowing for friction in pipes and ports gives 120 pounds initial pressure. As we wish to have about 5 pounds terminal pressure by the gauge, or 20 pounds absolute as before, the initial is divided by the terminal pressure, showing that the ratio of expansion must be 120 ÷ 20 = 6, the hyperbolic logarithm of which is 1.7918. Applying the formula already given for finding the mean effective pressure the result is:

$$\frac{1.7918 + 1 \times 120}{6} - 15 = 40.83 \text{ pounds.}$$

Changing the speed from 70 to 90 revolutions raises the piston speed to 630 feet and the power developed under the conditions is

$$\frac{314 \times 40.83 \times 630}{33,000} = 244 \text{ hp.,}$$

showing a gain of $244 - 158 = 86$ hp.

Another plan for providing more power when it is wanted is to put a crank on the other end of crank shaft of a single engine, then when the proper time comes the outside pillow block may be removed and a frame put in its place. This makes it possible to add another cylinder whenever wanted, thus doubling the power of engine. This is shown in Fig. 5. It gives $244 \times 2 = 488$ hp.

It is necessary to make calculations for a heavy increase of power when the station is first laid out, and design the crank shaft, flywheel, belt, main pulley and line shaft so that they will carry the greater load when wanted, as otherwise one or more of these parts will fail and cause trouble.

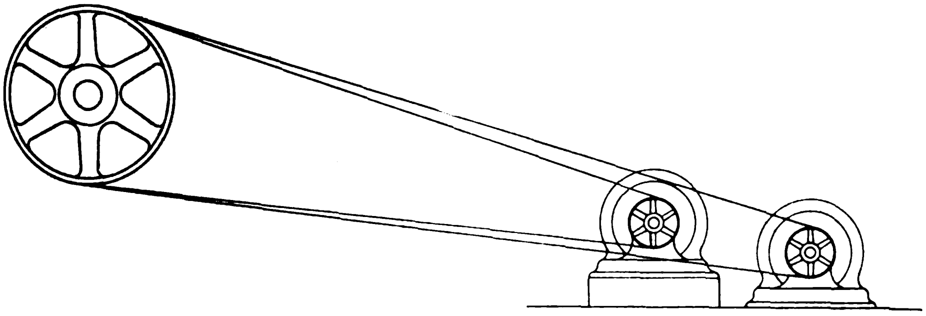

Fig. 6.

It will be noted in Fig. 5 that there are two dynamos in line. An elevation of this arrangement of belts and machinery is shown in Fig. 6. One belt is placed around the other, so that one driving pulley is used for two dynamos. Of course this makes it necessary to run both dynamos at all times when one is wanted, unless one belt is taken off, and that is not recommended, as it takes too long to do it, especially if the inner one is disabled. The writer has seen three belts run on one pulley in this way driving three dynamos.

Every pulley on the line shaft, as here shown, should be a clutch pulley, so that the dynamos it drives can be stopped at any time without interfering with others. To some engineers this caution may seem superfluous, but so long as cases can be found where clutch pulleys ought to have been used, but were not because they cost more than the plain kind, there is evidently chance for improvement. When we consider that electric stations and power plants are sometimes designed and built by men who are not mechanics, but who can consider the difference in price between a plain and clutch pulley equal to the greatest expert known to modern science, although they do not understand the difference in actual practice, it proves that plain directions along this line are very much needed.

After the second cylinder is added to the single engine, converting it into a double engine, it is not always necessary to run both of them, for if only a light load is to be carried for several days the connecting rod may be disconnected from the crank pin on one side and the valve gear may also be allowed to remain at rest while the other side carries the load.

With such an engine it is possible to carry loads that vary greatly, not only as shown by these calculations, but beyond the limits herein mentioned, for when the greater power is developed the cut-off takes place at one-sixth of the stroke, which may be exceeded and still secure a fair degree of economy. The extreme limit is still farther on, but so far as fuel is concerned it does not pay to overload an engine.

◆

SETTING TYPE BY TELEGRAPH.

The paper recently read by Mr. Donald Murray, before the Institution of Electrical Engineers in England, indicates a distinct advance in the science of telegraphy, and shows that the author has grasped the general principles which must govern the conditions under which fast speed working is commercially practicable. The expression "fast speed" is greatly misunderstood, and many of those who are experts in telegraph mechanism fail to understand the conditions under which fast speed can be made of commercial value. The one idea of these experts is to produce an apparatus which can "pour out" signals at a speed which has not hitherto been attained, utterly oblivious of the fact that the possibility of "handling" the received signals, transscribing the same and putting the result in an intelligible form for handing to the public, is a matter of vital importance. By some telegraph experts, the necessary commercial conditions are well understood, and the lines on which they are working are therefore perfectly sound; this is notably the case in regard to the Murray apparatus. Mr. Murray has continued to improve the instruments, with the result that the system is likely to prove of sterling value. In his paper, Mr. Murray points out that the object of machine telegraphy is not only to increase the saving of telegraph wire, but also to reduce the labor cost of translation and writing, by the use of suitable machines. The simplicity of these machines and the saving of wire-cost depend on the fewness and simplicity of the signals. For a given wire, the fewer the signals the more the business that can be passed over it; and for a given amount of business, the fewer the signals the cheaper the wire that can be used. And with the increase of distance the cost of the wire becomes all-important.

Although the Morse alphabet is ideal for manual signaling, it has a grave disadvantage for machine telegraphy. The letters are of unequal length. Only those who have made a careful study of the printing telegraph problem from a mechanical point of view, can realize the extreme importance of this question in constructing a printing telegraph. Uniformity is the key to success in machinery. It makes for simplicity. With all machinery, simplicity, other things being equal, is of prime importance, and owing to the delicacy and inherent imperfection of telegraphic machinery, the need for simplicity in this case is overwhelming. That simplicity can only be secured by a signaling alphabet in which all the letters are of equal length. It is the same necessity that has compelled the use of letters all of the same width in typewriters. The Morse alphabet, however, has been in possession of the field so long, and telegraph officials in English-speaking countries are so saturated with Morse traditions, that it would be impossible to introduce a new alphabet if the operators had to learn it. Fortunately, with machine telegraphy that is not the case. As a single illustration of the mechanical advantages of an equal-letter alphabet, such as that used on the Baudot and Murray systems, it may be mentioned that a keyboard perforating instrument to produce the Morse tape for the Wheatstone transmitter, requires a group of 19 punches and their corresponding parts, as against only five punches and their corresponding parts in the Murray keyboard perforator. As an automatic printing telegraph requires about four keyboard perforators at each end of a circuit, if an equal letter keyboard perforator can be constructed for $100, and an unequal letter perforator costs $300, there is a difference of capital cost of about $1,500 per circuit in favor of the equal-letter alphabet. This is a large item if many circuits have to be equipped, to say nothing of the fact that cost of maintenance is roughly proportional to capital cost.

Unquestionably the best alphabet for machine telegraphy is that used in the Baudot and Murray systems. It is the shortest of all practicable telegraph alphabets, in fact, the shortest possible, and it is an equal-letter alphabet, consisting of five units per letter. The permutations are made up out of impulses of 1, 2, 3, 4 and 5 units' duration, both positive and negative (or positive and zero). Being an equal-letter alphabet, the signals can be divided off into letters by measurement. There is, therefore, no need for a unison signal to separate the letters as in Morse. Hence there is no space between the letters. The result is that impulses frequently extend from one letter into the next, and the average number of marking impulses per letter in the Murray system is only about 1¼, and a trifle more in the Baudot.

The Murray system makes no attempt to secure synchronism. It is an isochronous system, and the duplex balance is used to secure working in both directions on one wire, the Murray system, like the Wheatstone, working very easily in this manner. Retardation under these circumstances ceases to be important, because the distributor need only keep step with the arriving signals, which might, if necessary, take five minutes on the journey. This arrangement has also the advantage that ordinary repeating stations can be used.

So far as commercial telegrams are concerned, a serious objection to direct-transmitting page-printing telegraphs is that errors show up badly in the printed message, and operators have to work slowly and carefully to avoid making mistakes. Telegraph operators are remarkably accurate, but in spite of the best care and skill errors are frequent. Any one who is accustomed to using a typewriter knows how difficult it is to write a page of typewritten matter without striking at least one or two wrong letters. In four cases out of five there is consciousness of the error as soon as it is made, and steps can be taken to correct it. In tape-printing telegraphs, like the Hughes and Baudot, the errors and the succeeding corrections can be cut out of the tape before it is pasted on the telegraph blank, and there is then nothing to disfigure the telegram and make the recipient uneasy about its accuracy. With a direct-transmitting page-printing telegraph this cannot be done. A wrong key depressed is an error printed at the other end of the line, and the correction following only magnifies the blot. All automatic systems of telegraphic transmission in which there is preparation of the message beforehand possess the potentiality of correcting an error before transmission. In the Wheatstone automatic system, for instance, this process is known as a "rub-out." When an operator at a Wheatstone puncher makes a mistake he can pull the tape back and punch it full of holes, thereby obliterating the mistake. In this case the mistake is represented by a series of dots on the receiving tape and the transcribing clerk passes over it. In automatic telegraph systems, in which a printing machine takes the place of the receiving operator, it is a comparatively simple matter to arrange that the printer shall imitate the action of the operator by remaining inactive when dots only are coming over the line. In this way no trace of the error appears in the printed message. This, for instance, is done in the Buckingham system. In the Buckingham system, however, as with Morse, the groups of letter signals on the transmitting tape are of varying length. It is consequently not possible to pull back the transmitting tape letter by letter in the keyboard perforator. It has to be adjusted by hand, or pulled back unit by unit, a process necessarily involving some loss of time, and many corrections in this way would materially reduce the output of the operator. In the Buckingham system also it is necessary to rub out everything as far as the end of the previous line. Hence, to correct a single letter a whole line may have to be rubbed out. With automatic systems like the Murray, using an alphabet in which the letter signals are all of the same length, the transmitting tape, while being prepared in the keyboard perforator, can be pulled back instantly letter by letter by depressing a lever. If an operator strikes a wrong key all he has to do to rectify his error is to strike the back-spacing lever, the letter-shift key and the desired letter—the work of a moment. A word of six letters can be blotted out in this way in a few seconds, and no trace of the correction, not even a blank space, will appear in the printed message at the other end of the line. This relieves the operator from the dread of striking the wrong key, the strain on his attention is less, and he can work faster without working harder. One or two automatic typesetting patents have included schemes for correcting errors in the perforated tape; but the Buckingham appears to be the first printing telegraph to adopt a plan for invisible correction, and the Murray system was the first, and, so far, is the only system having the power to correct instantly single letters or words.

The key buttons are in rows of different colors and of slightly different heights to facilitate operations without taking the eyes off the copy—an essential condition for high speed on a typewriter keyboard. This mode of working is not so difficult as might be supposed, particularly when the operator is trained from the first to write in this way. A young operator in Berlin learned to write on one of the Murray keyboards in a fortnight, at the rate of 120 letters (20 words) per minute, without looking at the keyboard, and this operator, after several months' practice, reached a speed of 436 letters (72 words) per minute in the same way. This is an exceptional case, and the operator was accustomed to piano playing, but it illustrates the possibilities of this method.

The speed of the Murray printer is now not less than 900 letters (159 words) per minute, and the automatic portion of the mechanism runs perfectly up to 200 words a minute. Unfortunately, however, no typewriter yet constructed will stand the strain of more than about 720 letters (120 words) a minute in continuous service. The received tape may be divided into sections and run through two printers when the apparatus has to be worked at top speed. Under existing conditions, however, high speeds for handling commercial messages are for many reasons undesirable, and a maximum of 120 words a minute in each direction seems to meet all requirements.

In practice with the Murray system—as with all other telegraph systems, from the Morse key upwards—the average output is not more than about 50 per cent. of the maximum. Time and patience will no doubt stop some of the leaks; but others, such as errors caused by line interruptions, seem to be incurable. The experience of the British Post Office is that five operators at each end of a Murray circuit, equipped with the apparatus in its original form, can exchange about 200 telegrams an hour, and under favorable circumstances occasionally as many as 240 per hour. With the new motor-driven printer, with automatic line feed, invisible correction of errors and other improvements, it is estimated that it will be possible for six operators at each end of a Murray circuit to exchange about 300 messages an hour. That is to say, 12 operators on one circuit will be able to do the work of 16 men on two Morse quadruple circuits, or at lower speeds eight operators will be able to do the work of 12. Actual tests show that the improved printer has a maximum speed of five messages a minute, so that the working average may be safely put at 150 messages an hour. A weak point with many telegraph systems is durability. In this respect the Murray apparatus has proved satisfactory.

Japan Increases Duty on Electrical Apparatus.

Electrical manufacturers will be interested to learn that a new tariff law has been enacted by the Japanese Diet and that it will go into effect July 1 next. A general increase of duties is noted all through the new law, presumably to enable Japan to gain additional revenue for the prosecution of the war with Russia. The new rates on electrical apparatus are as follows: Electric light apparatus and instruments and parts thereof, 15 per cent. ad valorem; telephones and parts thereof, 15 per cent.; copper wire, 15 per cent.; submarine telegraphic cables and underground telegraphic lines or cables, 20 per cent.

Crocker-Wheeler Company's Co-operative Plan.

A new co-operative scheme has been entered into between the officers of the Crocker-Wheeler Electric Company of East Orange, N. J., and its employes. It is in the nature of a benefit association. The men pay 10 cents a week. Each member is entitled to $10 a week for 20 weeks during disability and his family will receive $100 when he dies. The company will contribute an amount equal to the dues paid to the association.

AS OTHERS SEE US.

(From the "American Contractor," Chicago, April 1, 1905.)

A LIVE ELECTRICAL JOURNAL.

In these days when publications have multiplied to such an extent that no field, developed or prospective, is left unrepresented, class journals are liable to become narrow and uninteresting, except to those whose business follows the same general line. In other words, they are likely to contain too much distinct "shop" talk, and that presented in a too highly condensed form. But there is such a thing as publishing a newspaper which, while fairly entitled to that name and containing everything of real value from a scientific standpoint in the field it essays to fill, may prove of decided importance from a trade and commercial standpoint, interesting and enlightening the reader. Within this category must be placed ELECTRICITY, the well-known New York journal.

This paper, which must be accounted old in a field that is really new, amply justifies its title, and, without being technical, keeps its readers informed on all interesting and valuable occurrences in the world of electricity. It contains a large amount of original matter, written in an intelligible and entertaining way, from which one may secure ideas without employing a reference library. Attentive readers of this paper will overlook nothing of great value in the electrical line.

A GOOD WORD FROM MAINE.

OLD ORCHARD, Me., March 13, 1905.
Electricity Newspaper Company :

Inclosed please find one dollar for one year's subscription to ELECTRICITY. Was much pleased with sample copy and the promptness with which I received it. It compares favorably with journals which I am taking whose subscription price is three times that of ELECTRICITY.

Yours respectfully,
CLYDE R. L. SNOW.

A Book Worth Having.

The well-known concern, G. & C. Merriam Company, of Springfield, Mass., has recently placed on the market a new edition of Webster's dictionary, which should be in the hands of all business and professional men. This revised work, known as Webster's International Dictionary, was edited by W. T. Harris, Ph.D., LL.D., United States Commissioner of Education, and contains 25,000 new words and phrases. There are 2,380 quarto pages, and 5,000 handsome illustrations from new plates. It may or may not be generally known that Webster is now, and has been the standard authority in the Government Printing Office for the last 30 years.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED APRIL 4, 1905.

Electric Railways and Appliances.

786,316. Signal System for Railways. William G. Roome, Los Angeles, Cal. Filed Dec. 19, 1904.

786,368. Railway Signaling System. Joseph Lemire, Drummondville, Can., assignor, by direct and mesne assignments, to the Automatic Railway Signal Company, Limited. Filed Oct. 3, 1904.

786,489. Automatic Trolley-Pole Controller. Martin O. Dolson, Los Angeles, Cal. Filed July 28, 1904.

786,604. Railway Signal System. William E. Schieble, Miamisburg, O. Filed May 16, 1904.

786,628. Electric Indicator for Railways. Pierre I. Chandeysson, North Judson, Ind., assignor, by mesne assignments, to Robert D. Peters, Knox, Ind. Filed Feb. 13, 1904.

Electric Lights and Appliances.

786,518. Electrode for Arc-Lamps and Method of Making Same. Isaiah L. Roberts, New York City. Filed March 25, 1903.

786,727. Apparatus for the Manufacture of Glowers for Electric Lamps. Francis M. F. Cazin, Hoboken, N. J. Filed Feb. 2, 1903.

Electrical Machinery and Apparatus

786,320. Means for Rectifying Alternating Currents. Robert Siegfried, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed Feb. 12, 1904.

786,323. Electric-Motor Control. William D. Stivers, Jersey City, N. J., assignor to the C. W. Hunt Company, West New Brighton, N. Y. Filed Nov. 12, 1904.

786,325. Electrical Condenser. Percy H. Thomas, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed July 16, 1903.

786,338. Transformer Receptacle or Case. John H. Zimmerman, Newark, N. J., assignor to the Westinghouse Electric & Manufacturing Company. Filed April 18, 1903.

786,366. Bearing for Electric Meters. Darragh de Lancey and Herbert M. Smith, Great Barrington, Mass., assignors to the Stanley Instrument Company, same place. Filed Sept. 17, 1903.

786,378-379. Mechanical-Power Brake and Power-Brake. Louis Pfingst, Boston, Mass., assignor to the Pfingst Electric Manufacturing Company, Kittery, Me. Filed Jan. 23 and July 13 1904.

786,411 to 786,425. Magnetic Clutch or Speed-Accelerator, Method of Power Transmission, Alternating-Current Power Transmitting Apparatus, Synchronous Motor With Clutch, Method of Varying the Speed of the Load Driven by an Alternating-Current Motor, System of Operating Electric Vehicles Electric Speed Accelerator, System and Apparatus for Motor Control, and System of Controlling One or More Electric Motors. Henry H. Cutler, Milwaukee, Wis., assignor to the Cutler-Hammer Manufacturing Company, same place. First application filed Aug. 5, 1903. Latest application filed July 2, 1904.

786,506. Motor-Controlling Switch. Frederick Mackintosh, Schenectady, N. Y., assignor to the General Electric Company. Filed Feb. 17, 1904.

786,635. System of Control for Electric Motors. Arthur C. Eastwood, Cleveland, O. Filed March 21, 1904.

786,752. Circuit-Controlling Device for Motors. George W. Gilmore, Alliance, O., assignor to the Alliance Machine Company. Filed Sept. 15, 1904.

786,775. Electric-Motor Controlling Apparatus. Lars G. Nilson, Hoboken, N. J., assignor, by mesne assignments, to the Fisher Motor Vehicle Company. Original application filed May 15, 1902. Divided and this application filed June 10, 1904.

Telephones and Telephone Apparatus.

786,263. Telephone Attachment. Louis A. Bumgardner, St. Paul, Minn., assignor of two-thirds to John Dale and Francis C. Peabody, same place. Filed Aug. 16, 1904.

786,428-429. Selective Signaling System. Rudolph C. Deuben, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Manufacturing Company. Filed May 18 and Oct. 2, 1903.

786,444. Telephone-Transmitter. William Kaisling, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Manufacturing Company. Filed Nov. 23, 1903.

786,523. Telephone-Receiver Holder. Kate C. Seaman, New Orleans, La. Filed April 9, 1904.

786,588. Telephone-Receiver. William J. Murdock, Boston, Mass. Filed July 21, 1904.

786,589. Circuit Closing and Breaking Device. William J. Murdock, Boston, Mass. Filed July 21, 1904.

786,733. Memorandum Attachment for Telephones. John W. Currier, Boston, Mass. Filed Jan. 11, 1905.

Miscellaneous.

786,257. Electric Heater and Method of Manufacturing Same. Murray C. Beebe, Pittsburg, Pa., assignor to George Westinghouse, same place. Filed May 14, 1900.

786,376. Electrogasoline-Vehicle. Lars G. Nilson, New York City, assignor, by mesne assignments to the Fischer Motor Vehicle Company. Filed May 15, 1902.

786,396. Induction-Coil. Charles Adams-Randall, New York City. Filed Dec. 22, 1903.

786,542. Electric Heater. Louis P. Brown and Frank J. Holmes, Chicago, Ill. Filed Oct. 17, 1904.

786,577 Thermo-Electric Couple. Albert L. Marsh, Lake Bluff, Ill., assignor to William A. Spinks & Co., Chicago, Ill. Filed Oct. 18, 1904.

786,578. Combined Condenser and Leak-Coil. Walter W. Massie, Providence, R. I. Filed June 18, 1904.

786,696. Signal-Relay. Frederick K. Vreeland, Montclair, N. J. assignor to the Wireless Telegraph Exploitation Company, New York City. Filed Nov. 14, 1904.

785,704. Galvanic Battery. David L. Winters, Chicago, Ill. Filed Jan. 3, 1905.

785,776. Electroplating Apparatus. Louis Potthoff, Flushing, N. Y. Filed Dec. 1, 1904.

THE TELEPHONE WORLD.

Bell Company Surrenders to Independents.

After a fight that has continued over 10 years the American Bell Telephone Company has made its first surrender to the Independent companies in Iowa. It has always been the policy of the Bell Company to refuse to connect its lines or exchanges with others using any except Bell instruments, on which a high royalty is charged. The fight has resulted in the country being covered with a network of rival lines and rival exchanges being built in cities.

The Bell has defeated legislation in many States to compel connections. Now it is announced that the Bell Company has contracted with several Independents for connections, and will make the policy general. The Iowa Independents consider the victory finally won, and are jubilant. The struggle has cost millions to both sides.

Lower Telephone Rates in Illinois.

A recent meeting of the Central Illinois Independent Telephone Association has resulted in the adoption of a uniform toll rate for long-distance calls by the Independent companies. The new rate is from 25 to 50 per cent. lower than those at present in force.

For more than a year the Citizens' Telephone Company, of Racine, Wis., has contemplated the building of a new central station and installing of a new system. Deals have now been completed for the improvement. The building, costing between $12,000 and $15,000, will be modern in every particular. The Citizens' Company will expend between $50,000 and $100,000, and claim its lines will be the best and most perfect in use. At present it has close to 2,300 'phones rented. It is understood that the company will soon have connection with a toll system to extend all through Wisconsin, up as far as St. Paul, Minn., and south into Illinois. The Wisconsin Telephone Company will put in many new cables and make other improvements, its intention being to reach out for more business in Racine and vicinity.

The Independent Telephone Company is making preparations to test the rural telephone rate law passed by the last Kansas Legislature. The law provides that farmers who own and maintain their lines shall only pay 50 cents a month rent, instead of $1, as they have been doing heretofore. As the law is aimed at Lyon County and was passed at the instigation of Emporia farmers, the telephone company claims that it is class legislation and will try to get it revoked on this ground. On the other hand, the farmers are equally sure that the law will stand, as the company has a State charter, and the cut rate, although applying only to Lyon County, is a State law.

A number of business men of Noblesville, Ind. together with several Indianapolis and Cincinnati men, have organized a telephone company with a capital stock of $100,000, and will soon ask the council for a franchise to enter Noblesville. It is their intention to extend the lines throughout the country. No tolls will be charged to talk to any part of the county and the price of telephones will be reduced 25 per cent.

Independents Will Hire an Organizer.

The Ohio Independent Telephone Association, at its meeting in Columbus last month, decided to employ a salaried organizer, and the executive committee was empowered to make such other expenditures as might be necessary to promote the interests of the association.

To raise funds for this purpose the association made itself liable to an assessment for emergency purposes of not to exceed four cents per telephone in active service.

These officers were elected:

President, Frank L. Beam, Cleveland, and secretary-treasurer, Ralph Reamer, Columbus.

Plans are being made by capitalists of Willows, Cal., to build a telephone line from Elk Creek to Round Valley. This line will traverse a rich lumbering and cattle country, which has heretofore been without telephonic communication and will be of great benefit to the town of Covelo and the Government reservation in Round Valley, bringing them in touch with the outside world. Another undertaking is the building of a telephone line to Fouts Springs, from Willows, adding greatly to the convenience of several health resorts in Western Glenn and Colusa Counties.

Work on the first of a series of "farm" telephone lines, to be constructed by the Central District & Printing Telegraph Company into the rural districts of Allegheny County, Pa., has been started in Mifflin and North Versailles Townships. The lines are being built especially for farmers and others living in the country districts. The line into Mifflin Township will be connected with the Homestead exchange, and extended through South Homestead, Homestead Park, Lincoln Place, Bull Run and other districts, reaching almost into Greene County. The North Versailles line will be connected with the Turtle Creek exchange, and will extend over the hills and include the territory between Turtle Creek, McKeesport and Irwin. Another line has been built through Patton and Braddock Townships, north of Turtle Creek, including the territory on the Greesburg pike from Pitcairn to Wilkinsburg.

Telephone instead of telegraph orders now govern the operation of trains over parts of the central division of the Philadelphia, Baltimore & Washington Railroad.

The Colorado Telephone Company, of Denver, has filed incorporation papers, the capitalization being $10,000,000. A part of the company's operations will be in New Mexico, with headquarters at Albuquerque.

The citizens of Council Bluffs, Ia., recently voted to grant a franchise to the Independent Telephone Company. Out of a total vote of 2,809, there were but 962 cast against it.

The Milwaukee Railroad Company has decided to displace the telegraph with telephones at the stations at Millville, Hammond and Zumbro Falls, Minn.

The Home Telephone Company's new long-distance line between Downey and Los Angeles, Cal., was lately opened for business.

Automatic Electric Company's Contract.

An item appeared in the issue of ELECTRICITY of March 29 stating that the Automatic Telephone Company, of Chicago, had been awarded the contract for a private telephone system in the New Orleans, La., Naval Station. The company to whom the contract was awarded is the Automatic Electric Company, of Chicago, instead of the one mentioned.

The annual financial report of the Gainesboro Telephone Company, with headquarters at Sparta, Tenn., has been issued. The report shows the growth of its lines from a few miles in 1896 to 2,200 miles of line, and 25 exchanges at present. The capital stock paid in is $214,700. The operating and maintaining expenses and taxes last year were over $26,000, the gross revenue was $47,357.43, the dividends amounted to $10,093.50, and a reasonable amount was paid to the depreciation fund. The lines of this company extend through Tennessee and Kentucky. Its rates are materially below those proposed to be fixed by the Legislature.

A meeting of the stockholders of the Maryland Telephone Manufacturing Company in Baltimore has been called for May 1, to take action on the decision of the directors to dissolve the corporation. The company was organized for the purpose of manufacturing instruments and equipment for the Maryland Telephone Company, and its stockholders and officers are identified with the latter company. The February fire of last year burned out its plant and since then it has not been in operation

The Bertha Telephone & Telegraph Company has been organized in Opelousas, La, with a capital stock of $50,000. The company succeeds the Bertha Telephone Company, and will install a complete modern plant and extend its long-distance lines. The following are the officers: Albert B. Pickett, president: Charles B. Chachere, vice-president; Daniel L. Baker, secretary and general manager, and Paul A. Blanchard, treasurer.

With a capitalization of $10,000, the Buffalo, N. Y., Pole Line Construction Company has been formed to manufacture electric and telephone materials. The incorporators are W. E. Robertson, C. S. Saunders and A. G. Greenberg, all of Buffalo.

The Hager Telephone Company has been organized to build a telephone line from Hager City to Diamond Bluff, Wis., thence down the Trimbelle Valley. The officers are: President, Frank Way; treasurer, N. P. Jensen; secretary, J. W. Milton.

Telephone Incorporations.

The Cato & Meredian Telephone Company, Cato, N. Y.—to operate a line in the northern part of Cayuga County and a part of Seneca, Wayne and Onondaga Counties. Capital stock, $25,000. Incorporators: J. E. Casey, G. R. Hageman and J. K. Rich, all of Cato.

The Marissa Farmers & Merchants' Telephone Company, Marissa, Ill. Capital stock, $10,000. Incorporators: G. W. Norin, S. S. Boyle and W. E. Meek.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Carlisle, Ky.—A new stock company, with C. C. Cole as president; M. V. Bostain, vice-president; George A. Straus, secretary; John N. Riss, treasurer, has been organized for the erection of a new and modern up-to-date electric light plant to cost not less than $15,000. Work has begun and light is promised in 60 days, barring serious accidents.

Chatham, Ill.—Mr. Carr is making plans for establishing an electric light plant.

Columbia, Ky.—It is now an assured fact that this place is to have an electric light plant. Mr. W. R. Myers has purchased a plant with power sufficient to light the town.

Conrad, Ia.—W. J. Stanton is projecting an electric light plant for this city.

Connersville, Ind.—The Connersville Gas, Electric & Power Company was lately sold at receiver's sale to George B. Markle, of Hazleton, Pa.

Dayton, O.—The Dayton Electric Light Company, of which Dr. J. E. Lowes is president, and the Montgomery County Electric Light Company, which was recently incorporated, have been consolidated under the name of the Dayton Lighting Company. The new concern will have a capital stock of $2,500,000. A million dollars will be spent in equipment.

Ebensburg, Pa.—A new town will be built within one mile of this place. Among the modern conveniences will be an electric light plant.

Eldorado, Ark.—Poles have been erected and wires strung for the electric light plant here.

Escanaba, Mich.—Municipal lighting has proved a failure in this city, and by unanimous resolution of the common council the proposition of selling the city electric and gas plants to the highest bidder will be submitted to the voters at the spring election to be held this month. The property represents an investment of about $80,000.

Fenton, Mich.—The electric light and telephone systems here were considerably damaged by a recent thunder storm.

Jamestown, N. D.—The Jamestown electric light plant is to be enlarged and improved.

McKeesport, Pa.—An electric light plant is to be erected in this city this spring.

Milton, Wis.—Prominent citizens of this place and Milton Junction are talking strongly of organizing an electric light and power company for the two places.

Montreal, Can.—The city council of Calgary has authorized the installation of an electric plant for street lighting at a cost of $60,000. R. S. Kelsch, of this city, is consulting engineer.

New Franklin, Mo.—The action of the city council in granting an electric light franchise to T. H. Todd and Wallace Estell, of this city, was ratified by practically a unanimous vote of the citizens at a special election held for that purpose last month.

New Paltz, N. Y.—Electric lights are to be installed here.

Pennsburg, Pa.—The council has granted an electric light franchise to a stock company.

Wernersville, Pa.—The Wernersville Electric Light, Heat & Power Company, with a capital of $5,000, has been incorporated.

Woodhull, Ill.—Fire lately destroyed the electric light plant here.

STREET RAILWAYS.

Albany, N. Y.—The Wallkill Transit Company of Middletown (reorganizing the Middletown-Goshen Electric Railway Company) has been incorporated. Its capital stock is $350,000, and directors: W. M. Oglesby, Harrisburg, Pa.; H. B. Royce and M. Benjamin, of Middletown. N. Y.

Baraboo, Wis.—C. C. Downer of the Red River Valley Electric Railroad Company has been trying to secure a right-of-way from Clintonville to Antigo via Eland Junction.

Carlisle, Pa.—The Cumberland Valley Railroad Company will equip all of its branch lines with the third rail for electric service.

Charlevoix, Mich.—There is talk of building an electric line this spring from Norwood to this city, a distance of three miles.

Columbia, Ind.—The proposed electric line from here to Goshen will run directly north from Syracuse to Benton.

Decatur, Ill.—Henry W. Knight has organized a company for the purpose of constructing an electric line connecting this city with Bloomington.

Gulfport, Miss.—The Gulfport & Mississippi Coast Traction Company proposes to build an electric line connecting the coast towns of Gulfport, Pass Christian and Biloxi. The company has been organized with a capital stock of $1,000,000.

Hagerstown, Md.—Official announcement of the purchase by the Cumberland Valley Railroad Company of the Chambersburg & Gettysburg Electric Railway system was lately made by M. C. Kennedy, vice-president and general manager of the Cumberland Valley Railroad Company.

Joliet, Ill.—This city and Pontiac will be connected by an electric railroad soon.

Kansas City, Mo.—The Kansas City & Leavenworth Electric Railroad has been sold to Clarence S. McClelland, of Mount Vernon, N. Y.

Lakewood, N. J.—Abner P. Gant, of this place, and L. D. Van Note and Robert Allen, of Point Pleasant, have been appointed commissioners to condemn lands near here for the Trenton, Lakewood & Atlantic Railroad Company's right of way for the trolley line from this place to Point Pleasant. Work is in progress and Lakewood will soon be connected with the seashore by trolley.

Lewisburg, W. Va.—A trolley line will be constructed between this city and Ronceverte.

Long Island City, N. Y.—By the time the season opens, in June, the Long Island Railroad Company expects to have its electrical equipment on the Far Rockaway branch and the line across the Jamaica Bay trestle to Hammels and Rockaway Beach fully installed.

Mannington, W. Va.—The city council has granted a franchise to the Mannington Light & Power Company for the purpose of constructing an electric line in this city.

Niagara Falls, N. Y.—At an early date the inclined railway in Prospect Park will be operated by electricity instead of hydraulic power.

Rockville Center, N. Y.—The South Shore Traction Company has been granted a franchise for a trolley road along the route proposed by it.

Sea Cliff, N. Y.—A number of local business men will petition the Long Island Railroad Company to make a trolley connection between the beach and this village.

Spearfish, S. D.—Articles of incorporation have been filed for a company which will finance the electric trolley line between this city, Belle Fourche and the Northern Hills towns. The stock will be sold to business men, and it is expected the road will be in operation before January 1.

Syracuse, N. Y.—A recent report from Rochester states that the Westinghouse-Kerr-Church Syndicate, which recently purchased the Rochester & Eastern Electric Rairoad, running between Rochester and Geneva by the way of Canandaigua, had secured the Geneva, Waterloo & Seneca Falls road, which extends from Geneva to Seneca Falls, giving it a line from Rochester to Seneca Falls. The report revived the rumor that the Geneva, Waterloo & Seneca Falls road would be extended to Auburn, the only gap in the trolley system between Rochester and Syracuse, through the territory covered by the Auburn branch of the New York Central. Such an arrangement would doubly connect this city with Rochester by trolley, the Rochester, Syracuse & Eastern road now building practically parallel to the main line of the Central.

POWER PLANTS.

Decatur, Ind.—The Springfield-Fort Wayne Interurban Company, of which W. H. Fledderjohn is manager, will erect a new power plant in this city.

Indianapolis, Ind.—The erection of a power plant in the heart of the Indiana coal field, for the generation of enough electricity to furnish all the power needed by the traction lines of Southern and Central Indiana, is a project that has been proposed to traction men of this city.

Minneapolis, Minn.—The Minneapolis General Electric Company will erect a new power plant which will furnish 24,000 hp. The sum of $3,500,000 is to be expended.

Ohiopyle, Pa.—The harnessing of the Ohiopyle Falls is again being agitated and this time the Wheeling, W. Va., men, who are behind the scheme, are said to have enough enterprise and money to put the matter through.

Pentwater, Mich.—Business men interested in the forming of a company to furnish electric current for lighting and heating purposes by water power have been making investigations of the possibility of damming the Pere Marquette River, near Colfax Township line, where the river is very narrow and hills on both sides. If this is accomplished, power, heat and light could be furnished to all the towns and villages of both Oceana and Mason counties.

BIDS WANTED.

Meridian, Miss.—Bids will be received May 1 for furnishing 200 arc lights, 1,200 cp., for a period of five years from May 1, 1906. Bids will also be received at the same time for other lamps. Address J. H. River, mayor.

Newport, Ky.—Sealed bids will be received by Peter J. Krebs, city clerk, until April 14, for furnishing and installing a storage battery system.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 15⅛@15¼c.; Lake 15¼@15⅜c.; casting, 14⅞@15c.

The "conservative, strong interests" in General Electric say the stock will cross 210 in June.

The Everett-Moore electric railway companies in Ohio are reporting increased earnings for the month of March.

An official of the National Carbon Company says there is fair prospects of another dividend on the common stock in May or June.

The Massachusetts Railroad Commission has authorized the Boston Elevated Company to issue $7,500,000 4 per cent. 30-year bonds.

The New York Assembly Railroads Committee has reported favorably the Dale bill, providing for a 3 per cent. State tax on the gross earnings of street railways.

The Brooklyn Rapid Transit Company has applied to the New York Stock Exchange to list $1,750,000 additional refunding mortgage 4 per cent. bonds of 2002.

The Boston Stock Exchange has listed 47,969 shares of common stock and 47,119 shares of the preferred stock of the Boston Suburban Electric Companies.

Opposition to the proposed sale of the Springfield (Mass.) Street Railway has agreed to pool the stock with a view to obtaining better than $225 per share—offered by New Haven.

The Massachusetts Railroad Commission has authorized the Boston & Northern and Old Colony street railway companies each to issue $500,000 additional stock at $100 a share.

The most interesting feature in copper circles is the report that large sales, probably about 10,000 tons, of electrolytic have been made for export, mainly to Europe, during April and May.

The Brooklyn Rapid Transit Company has made a bid to construct subways, and in financial circles it is believed that the company has entered into a combination with the Metropolitan system of New York.

The Electric Textile Machinery Company has been incorporated under Massachusetts laws with a capital of $1,000,000 to deal in textile machinery. Of the capital $300 was paid in in cash and patents were represented by 99,997 shares.

A special meeting of the Philadelphia Rapid Transit Company's stockholders has been called for April 25, to authorize the company to join as surety and guarantor in a mortgage of the Market Street Elevated Passenger Railway Company.

There is talk of a combination between the American Locomotive Company and the General Electric Company, based on the fact that the two companies have a great many joint orders for electrical locomotives and the belief that this department will grow materially.

The Gas & Electric Company of Bergen County, N. J., recently voted to make a new $5,000,000 mortgage to replace the one made November 1, 1904, with the Bowling Green Trust Company, trustee, and authorized the exchange of the $800,000 bonds issued thereunder for a like amount of bonds to be issued under the new instrument.

Of the new $1,250,000 issue of 5 per cent. 20-year bonds of the Columbus, Newark & Zanesville (O.) Electric Railway Company $400,000 have been taken by Baker, Ayling & Co., Boston, and $800,000 by the Electrical Securities Corporation of New York, the Union Electrical Securities Company and the Railways & Securities Company of Boston. There are still $750,000 reserved for extensions.

EDITORIAL NOTES.

The Electrical Safety of New York.

The word electricity to the layman means shock, and to the ignorant, sudden death. New York now represents such a complicated network of wires overhead and underground, that to some extent at least a natural fear has been aroused in the minds of many citizens that danger lurks on every side. The deadly third rail, the fatal electric light wire are common expressions. To what extent life is unsafe in New York through the electrification of its surface, elevated and underground roads, through the installation of hundreds of thousands of incandescent, and many thousands of arc lamps, is well worth inquiring into. If unsafe, why is so great an evil allowed to remain. But if the electrical safety of New York is an assured fact, then such misconceptions should be dispelled. They belong to the traditions of the past.

The requirements as regards insulation are so rigid in the electrical equipment of new buildings that from this source at least no danger can be expected. The iron conduit system is thoroughly efficient as a measure of protectiveness. The same reasoning applies with equal force to the subterranean system of conduits extending from one end of New York to the other. Lead-covered cables carry the electrical energy from point to point, and the danger from any cause whatsoever is thus reduced to a minimum. But if the wires are so well insulated, does it necessarily follow that this insulation is employed as a protection for the sake of the public against accidents? We hardly think so, and for reasons which, with but two exceptions, will appeal to intelligent minds. These exceptions are the case of high tension alternating current wires, which are always underground and possibly from the third rail. A high tension alternating current is a deadly current to take and few are left to tell the tale after such an experience. But with the third-rail, conditions are different. Five hundred volts direct current is not deadly, in fact, railway men do not regard it as such, and would pass a matter of that kind by without a word. If the third-rail is at this pressure with respect to the other two tracks, then why do sensational reports appear about the deadly third-rail? We do not wish to destroy the deeply unplanted fear of our readers for their safety when such risks are present, but it is well worth knowing that contact with 500 or 600 volts is not necessarily fatal.

This assurance is of great value when accidents occur. It will at least act psychologically upon the will and give it resisting power. In some human organizations, a sensation that can only be interpreted as fear, will cause death. To such, mere contact with wires carrying moderate pressures would invite heart failure. Physiology and psychology are thus interlinked in their evil results, and as a proof of it, hundreds are alive and well through whose systems 500 volts have passed. New York is therefore electrically safe, and where high pressures are transmitted, safety is absolutely assured by the splendid underground conduit systems employed.

* * *

The Electrical Origin of Rain.

The vivid flash of a million volts and the short report or insistent rumbling are but the consequences of a chain of events which link this sphere of ours to the gigantic father planet, the sun.

In the light of our present knowledge we speak advisedly when we say the earth and sun are linked together by bonds of indestructible ether. Not only are they linked together, but the least indication of disturbances on the sun finds its echo in the far distant abysses of space. This earth and all the other satellites are instantly affected, and the terrestrial equipoise is temporarily disturbed, responding to invisible stimuli that advance like gigantic tidal waves upon surrounding heavenly bodies.

The cyclonic storms sweeping over the sun's surface are of almost incomprehensible grandeur. Great cataclysms of fire and incandescent vapor propelled by inward forces whose origin and character can be but faintly estimated rise to enormous heights. From these titanic pillars and flaming maelstroms are poured forth showers of corpuscles. They advance beyond the influence of gravitation and sweep across the ether bridge between the sun and earth with prodigious speed. With them, but far in advance, moving on with the swiftness of light are the infinitesimal vibrations awakened by these convulsions. It is like the exploration of a strange new land filled with wonders to look into the spectrum through the savant's eyes and view these pertubations of the ether with respect to their influence upon the existing order of things. To-day our greatest hope lies in an interpretation of natural phenomena through a comprehension of their functions. They awaken the twig and blossom, destroy the deadly germ and act as the most potent of forces in reconstructing the forms of inorganic matter. The rainfall is among the most important of all the phenomena directly attributable to the presence of the solar corpuscles. They are the nuclei around which the vesicle of vapor condenses, and this continuous and aggregated condensation is apparent in its final form as rain.

Strange as it may seem, science has advanced and in many respects proved this theory. The experiments of Sir Oliver Lodge have added their more convincing quota of evidence. He attacks the fog directly with his electric discharges, but the sun 92,000,000 miles away sends forth its myraids of messengers, each carrying its elementary charge of electricity which penetrate the banks of vapor accumulating in the higher strata of the earth's atmosphere. Here the drama of meteorological action transpires. The vast cumulus clouds are sprayed by this bird shot of nature, and the drops appear and fall to the distant earth. The inductive influences begin to operate as the process of condensation advances, and the charged clouds separating into mountainous masses of electrified vapor send into each other the forked flashes or silent sheet discharges so characteristic of the two degrees of condition.

The advance of spring heralds these events, and when in conjunction with this annual visitation we hear of the great sun spots lately witnessed, it is not too far-fetched to expect unusual disturbances in the upper atmosphere, not the least of which will be abundant lightning discharges.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

Mayor Dunne of Chicago will probably organize his local transportation department along lines followed by private corporations.

Charles H. Baker of Seattle, Wash., will sail for China in May to engage in building a trans-China electric railway system in that empire.

A report from Montreal, Can., says that there is a movement on foot to have the Carillon and Grenville canals lighted by electricity.

The United States Circuit Court for New York in its decision in a suit by the Marconi Company against the De Forest Wireless Telegraph Company sustained the claim of the plaintiff company to the priority of the invention of a system of wireless telegraphy.

The Hotel Astor in this city makes use of the telautograph to transmit orders from the eighth floor, where all the large dinners are held to the ground floor.

The last reunion of members of the American Society of Mechanical Engineers in New York City, previous to the Scranton meeting, will be held on Tuesday evening, April 25, at 12 West 31st street. The paper of the evening will be by Mr. Gus C. Henning.

A cable dispatch from Frankfort-on-the-Main says that an amalgamation of the Lahmeyer Electrical Company and Felton & Guilleaume of Mulheim, Germany, has been effected, with a capital of $13,750,000.

The annual report on municipal ownership, to be presented by Mr. Arthur Williams to the Denver-Colorado Springs convention of the National Electric Light Association, will contain over 50 reports from foreign cities and towns, as well as a great quantity of information regarding municipal plants in this country. His report will be very voluminous and forms a notable addition to the literature relating to municipal electric lighting.

The seventh general meeting of the American Electrochemical Society will be held at Boston and Cambridge, Mass., Tuesday, Wednesday and Thursday, April 25, 26 and 27.

A dispatch from Watertown, N. Y., April 17, says: "Dr. Alfred Goss of Adams, as the result of long research in the realm of electro-therapeutics, is said to have worked out a treatment for tubercular troubles that promises the possibility of a cure. While the results of the treatment in the 44 cases that Dr. Goss has had are most gratifying, he says he is not yet prepared to state that the treatment is an assured success. Dr. Goss has succeeded in introducing by means of static electricity a germicide that will not affect the albumen of the blood, and has been proved to kill tubercle bacilli in lung tissues."

A dispatch from Cleveland, O., says the financial affairs of the Everett-Moore Syndicate, which went into the hands of a bankers' committee three years ago for liquidation, have been settled and the last creditor has been paid. The syndicate controlled a number of traction lines, electric light plants and telephone systems in and near Cleveland. The total amount of this firm's holdings reached into the millions.

Mr. Frank L. Perry, Marquette Building, Chicago, has been appointed assistant master of transportation, for Chicago and adjacent territory, with the particular duty of working up a special train from Chicago to Denver-Colorado Springs, which will be run in connection with a special train from New York for delegates to the National Electric Light Convention.

The economy from electric power in loading ships with grain, says the "Electrical Engineer," London, is illustrated by some tests lately carried out at Geelong, Australia. With three machines in operation for 8½ hours no less than 5,320 bags of wheat were handled on a current consumption of 42 kilowatt hours. At 5 cents per unit the work cost $2.10, a remarkably low figure for the quantity of material handled. It is estimated that a ship with a capacity of 20,000 bags of wheat can be loaded on this system for $8.75, while if the elevation to the ship's side were not too great to allow of two or three bags being placed on the belt, the cost of energy would be brought down to little more than half.

A PORTABLE WIRELESS TELEGRAPHY APPARATUS.

Some time ago the Gesellschaft fur Drahtlose Telegraphie in Germany brought out a portable wireless telegraphy installation which was made use of for reporting the James Gordon Bennett motor-car race. Since then, according to the "Electrician," London, progress has been made, especially in the direction of lightness of apparatus, and the latest wireless equipment may be carried from place to place by ten or eleven men.

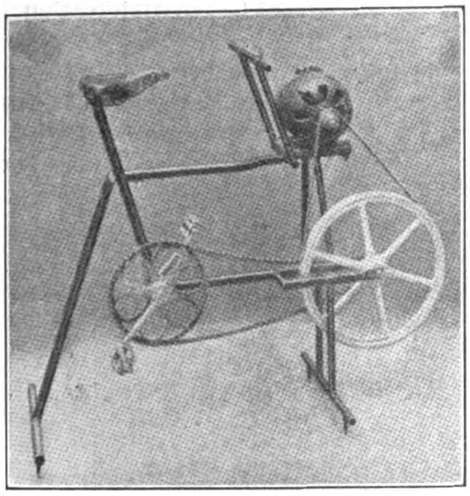

Fig. 1.
Treadle Arrangement for Generating Current for the Portable Wireless Telegraph Installation.

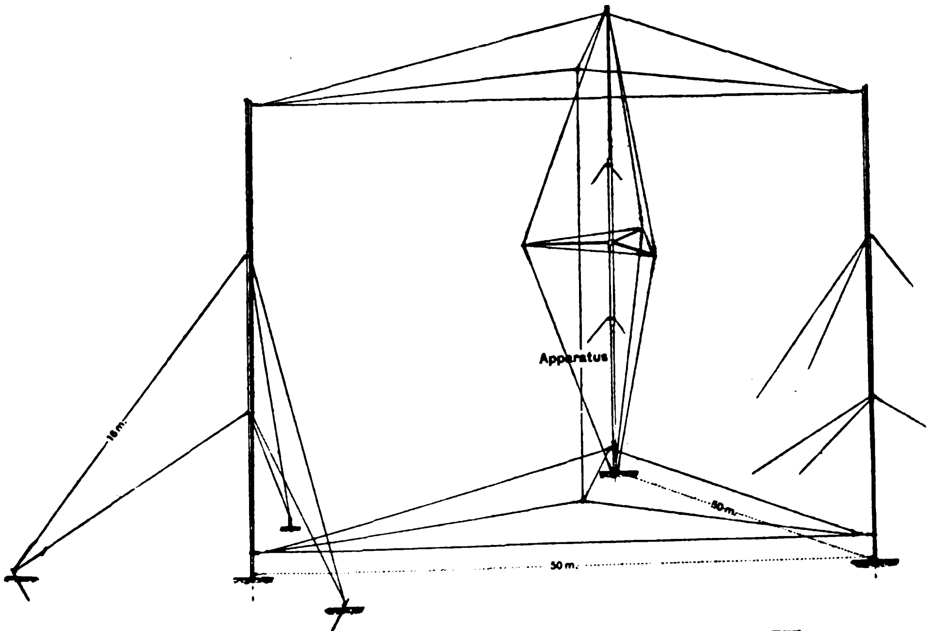

Fig. 2.—Arrangement of Aerial Wires of the Portable Wireless Telegraph Installation.

Ten men only are required when current is generated by a dynamo in the manner shown in Fig. 1, but eleven men are necessary if accumulators are used for supplying the current. The total equipment may also be loaded on three horses, the first horse carrying the masts, the second horse the transmitting and receiving instruments and the third horse either the dynamo or storage battery. Each piece of apparatus is placed in a bag of oilcloth for transport. The total net weight of a station is stated to amount to 445 lbs. when the dynamo is used and 510 lbs. when a storage battery is employed. Recent experiments, according to the company, have proved that a distance of about 15½ miles across flat country may be negotiated with three masts arranged as indicated in Fig. 2, each mast being 10 meters (31½ feet) high. The masts weigh 44½ lbs. apiece (including all tackle), this small weight being rendered possible by using steel tubes. When these are telescoped for transport their length is reduced to 12½ feet. The stability of the masts is increased by cast-iron base plates and suitable stays as shown in Fig. 2. Tinned copper cable, consisting of eight wires 0.4 mm. in diameter and supported by glass insulators is used for the aerial wire. The small continuous-current dynamo shown in Fig. 1 has an output of about 100 watts. It weighs, complete with driving arrangement, some 65 lbs. When the dynamo is not employed a 16-volt (8-cell) battery is used, having a capacity of about 30 ampere hours at a 5 hours' discharge rate. The accumulator cells are fitted in ebonite boxes, and these again are packed into two wooden boxes, each of which is 11½ inches high, 6¾ inches wide and 1 foot 1½ inches long and weighs about 65 lbs. The transmitter is also mounted in a wooden box, this box measuring 1 foot 9 inches by 9 inches by 1 foot, and weighing complete about 45 lbs. It contains, among other things, a Morse key, an inductor with hammer interrupter, a Leyden battery of six jars, the excitation coil tuned for a wave length of 400 meters (440 yards), a spark gap with zinc electrodes, etc. Even lighter is the receiving station which weighs only about 33 lbs. It consists of an electrolytic detector of the Schloemilch type, a pair of telephone receivers, a condenser, four dry cells, a contact box and so on. These apparatus are mounted in a box 1 foot 3¾ inches by 9¾ inches by 9¾ inches.

BIMETALLIC RHEOSTATS.*

BY F. PUNGA.

The choice of the proper material is one of the most important factors in the construction of rheostats; in fact, for starting rheostats where ventilation is of little importance, the problem is to directly store up a certain amount of heat in the cheapest way.

As the usual material for rheostats—wire of high specific resistance—is rather expensive, the attempt has been made to improve the heat-storing capacity by winding the wire directly on porcelain or on iron tubes, insulated by thin sheets of asbestos, or on asbestos tubes impregnated with special chemical substances and baked.

The inherent fault of all these arrangements is the sluggishness with which the heat is taken up by the surrounding materials.

Quite a different solution of the problem is the use of iron as resistance wire. This obviates the necessity for employing any other heat-storing materials, as iron is so cheap that a liberal quantity may be employed in the design.

This method has, however, a great lack of flexibility. Whilst very useful for currents up to 5 or 10 amperes, it is impracticable for larger currents to use one single wire, as the cross-section would be too large for bending, and one has to employ two or three, and often as many as six, different wires in parallel.

This leads to a series of disadvantages, especially if a good many steps are employed for the rheostat switch, as taps often have to be taken from the middle of a tube. If there are, say, six tubes in parallel, this means six taps for one rheostat step.

A solution, which is to a certain extent free from the faults of the above methods, has been devised by Mr. Hobart and the writer has helped in the development of this so-called "bimetallic rheostat." The chief material for storing up the heat is iron, but the current is conducted almost entirely by a copper winding which is in close metallic contact with the iron wire. The latter is able to absorb the heat from the copper very quickly; in fact, tests have shown that the copper winding can be designed quite independently of thermal considerations; the cross-section can be chosen so small that the wire would fuse instantaneously if suspended in free air.

---

*From the "Electrical Review," London.

The current density employed in a copper wire of 0.27 mm. was 250 amperes per sq. mm., or 150,000 amperes per square inch, and after 120 seconds the temperature of the wire was only just high enough to soften common solder.

By this means it is possible to obtain a rheostat in which the heating is taken care of by the iron wire and the exact resistance is obtained by choosing the copper of different cross-section. As the iron wire is preferably always of one and the same diameter, the copper cross-section being, however, very small, the general appearance of a rheostat for 15 amperes is about the same as one for 75 amperes.

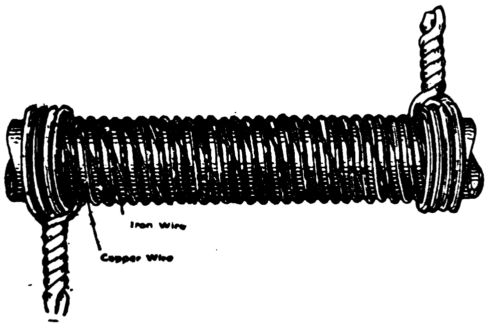

Fig. 1.

In the normal rheostats the iron wire is wound with about 6 turns per cm. length; the copper wire two or three in parallel, having only one-half turn per cm. length of tube. Iron wire and copper wire are in parallel, but as the former has a considerably greater length and considerably higher specific resistance only a small percentage—often from 5 to 15 per cent.—of the total current flows through the iron wire. This construction is shown in Fig. 1; the maximum current that can be conveniently carried in this way is about 100 or 150 amperes. Fig. 2 shows a tube for 125 amperes. It will be noticed that the greater the current the steeper becomes the pitch with which the copper wire is wound. For higher currents the construction in Fig. 3 is used which construction, in the form of honeycombs, can be used for almost any current.

The winding of the tubes shown in Figs. 4 and 5 has been done by hand, but, of course, to reduce labor cost, machine-wound rheostats would be employed in the factory, and suitable terminal caps would also be substituted for the twisted wires shown. The iron and copper wires can either be woven through each other in the manner familiar in covering copper wires with cotton insulation, or they could be wound in three stages: (1) One spiral of iron wire; (2) the copper winding; (3) a second spiral of iron winding between the turns of the first spiral.

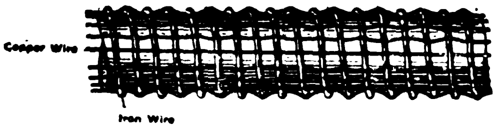

Fig. 2.

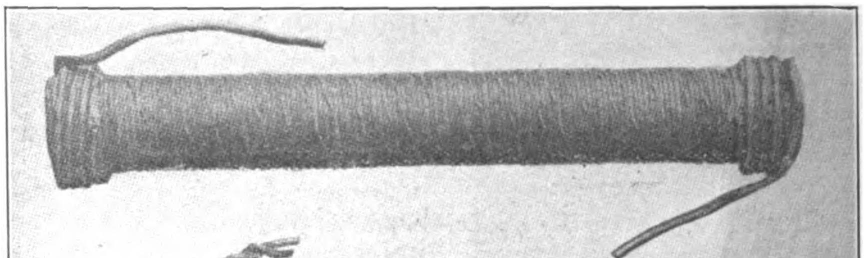
Fig. 4.



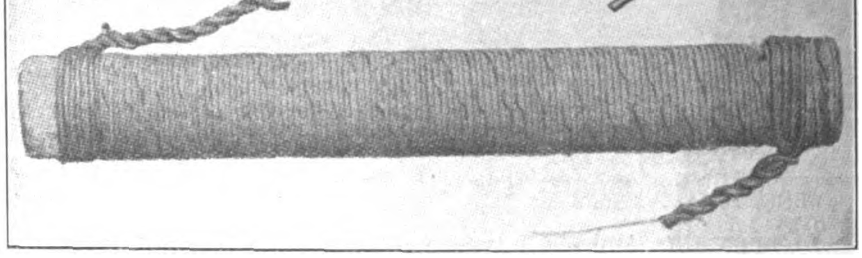


Fig. 5.

The winding itself is, however, not done for each tube separately, as is a necessary condition for the ordinary rheostats, but may be done in large quantities, 10 or 20 being wound in one continuous piece; terminals are wound round at suitable distances apart after the total length is wound and then single tubes are sawn out.

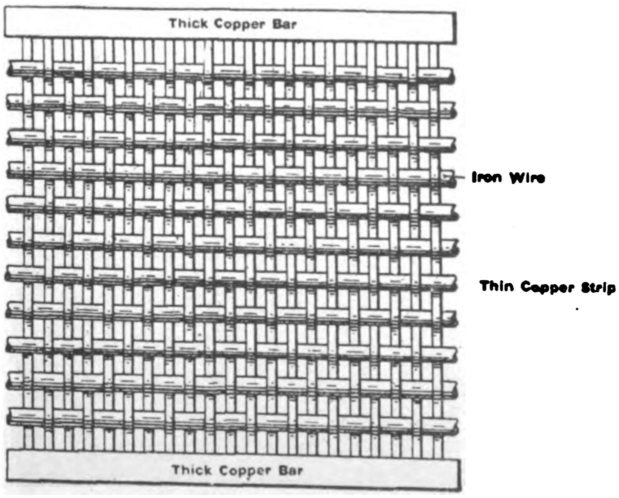

Fig. 3.

As there are generally no tubes in parallel, it is clear that the distance between two adjacent taps must be as many times larger as there are tubes in parallel for the ordinary construction; or, in other words, the length of a single tube can be chosen considerably larger than in the normal rheostats, and even then no taps from the middle of a tube will be necessary.

A Year's Work at the British National Physical Laboratory.

The following is a brief summary of the work accomplished at the British National Physical Laboratory at Bushy House, Teddington, during the past year:

In the physics department the work included among other things a comparison of the mercury standards of resistance constructed in the previous year, the investigation of certain anomalies in standard cells, of both the Clark and cadmium patterns, the construction of the electrical portions of the ampere balance for the British Association, and numerous tests of the dielectric resistance of different varieties of gutta-percha. Progress was made in equipping an electro-technical department to undertake the testing of electrical apparatus on a commercial scale, and electrical research work was carried out on behalf of the Engineering Standards Committee to determine the maximum temperature permissible in electrical machinery.

In the therometric department a considerable amount of new apparatus was installed and the work included the final stages of a research on the specific heat of iron at high temperatures and the beginning of a study of the resistance and thermo-electric properties of solid electrolytic conductors such as are used in Nernst lamps, with the view of designing a system of electrical high-temperature measurements based on some of the properties of zirconia, yttria, etc.

In the metallurgical department extensive tests were carried out on a series of nickel, carbon, and manganese iron alloys, prepared by Mr. Hadfield at the Hecla Works, Sheffield, and also an inquiry into the critical ranges on heating and cooling of modern high-speed tools.

In the photometrical department, intercomparisons were made by means of glow lamps with the National Standards Bureau, Washington, and the Electrical Testing Laboratories, New York, as well as with the Berlin Reichsanstalt, and further investigations are now being undertaken to determine the ratios between the standards of candle power accepted in America, Germany, France and Great Britain.

In the engineering department the standard leading screw lathe was fitted with a compensating bar to correct its errors and it is now true to within 0.0001 inch over the length of 36 inches. It has been used to cut a screw for Armstrong, Whitworth & Co., the errors in pitch of which, measured from one end, lie between — 0.0003 and + 0.0002 inch in a length of 36 inches. The effects of wind pressures on structures and the resistance of materials under alternating stresses have also been under investigation.

Much of this work is being continued during the present year, and among new researches proposed may be mentioned the influence of impurities on copper, the relation of carbon to iron in cast-iron, and the so-called constituents of quenched steels, the last being organized on an international basis.

PROVIDING FOR INCREASE OF POWER IN ISOLATED STATIONS.

ARTICLE V.—(*Concluded.*)

BY W. H. WAKEMAN.

The condenser has not been brought into these articles previously, as it may be applied to all engines mentioned with good results, therefore it belongs in the latter part of this series.

I have frequently objected to the statement which informs us that the addition of a condenser to a non-condensing engine makes it develop more power, for the simple reason that it is not correct. We are constantly seeking for devices and appliances that will cause our engines to develop less power and still do the work we want in every-day practice. This is a logical and business proposition, and when we add a condenser to a non-condensing engine the useless resistance to the piston of that engine is reduced, which is all that anybody can successfully claim for the change.

The following brief statement is presented for very careful consideration. The total load carried by an engine, as represented by a complete indicator diagram, may be divided into three parts as follows:

First—The part represented by the area of diagram.

Second—The resistance shown by the area of a space bounded on the top by the counter-pressure line (including the compression line) and on the bottom by the atmospheric line.

Third—The area of space bounded on top by the atmospheric line and on the bottom by a line representing a perfect vacuum under existing atmospheric conditions.

The first will remain the same after a condenser is added, although the shape of diagram will be changed. It is assumed that the same dynamos are operated and that neither voltage nor amperage are changed.

The addition of a condenser takes away the second altogether and it removes about three-quarters of the third, therefore it reduces the load shown by these two, forming a logical reason for the fact that when a condenser is added less coal is required. More power is not developed when considering the total load, but less.

Now if more dynamos are started, thus increasing the first item until it compensates for what is taken from the second and third, the result is that by adding a condenser and running more dynamos some of the useless work has been changed into useful work, and more electric lights can be furnished without increasing the coal consumption.

Fig. 7 illustrates an injector condenser as applied to this double engine, with a valve in each exhaust pipe, so that either can be shut off at pleasure. With the condenser in operation and both engines connected to it, also with enough more dynamos in use to keep the point of cut-off at one-sixth stroke, as assumed in a previous calculation, this engine will develop a mean effective pressure of 53

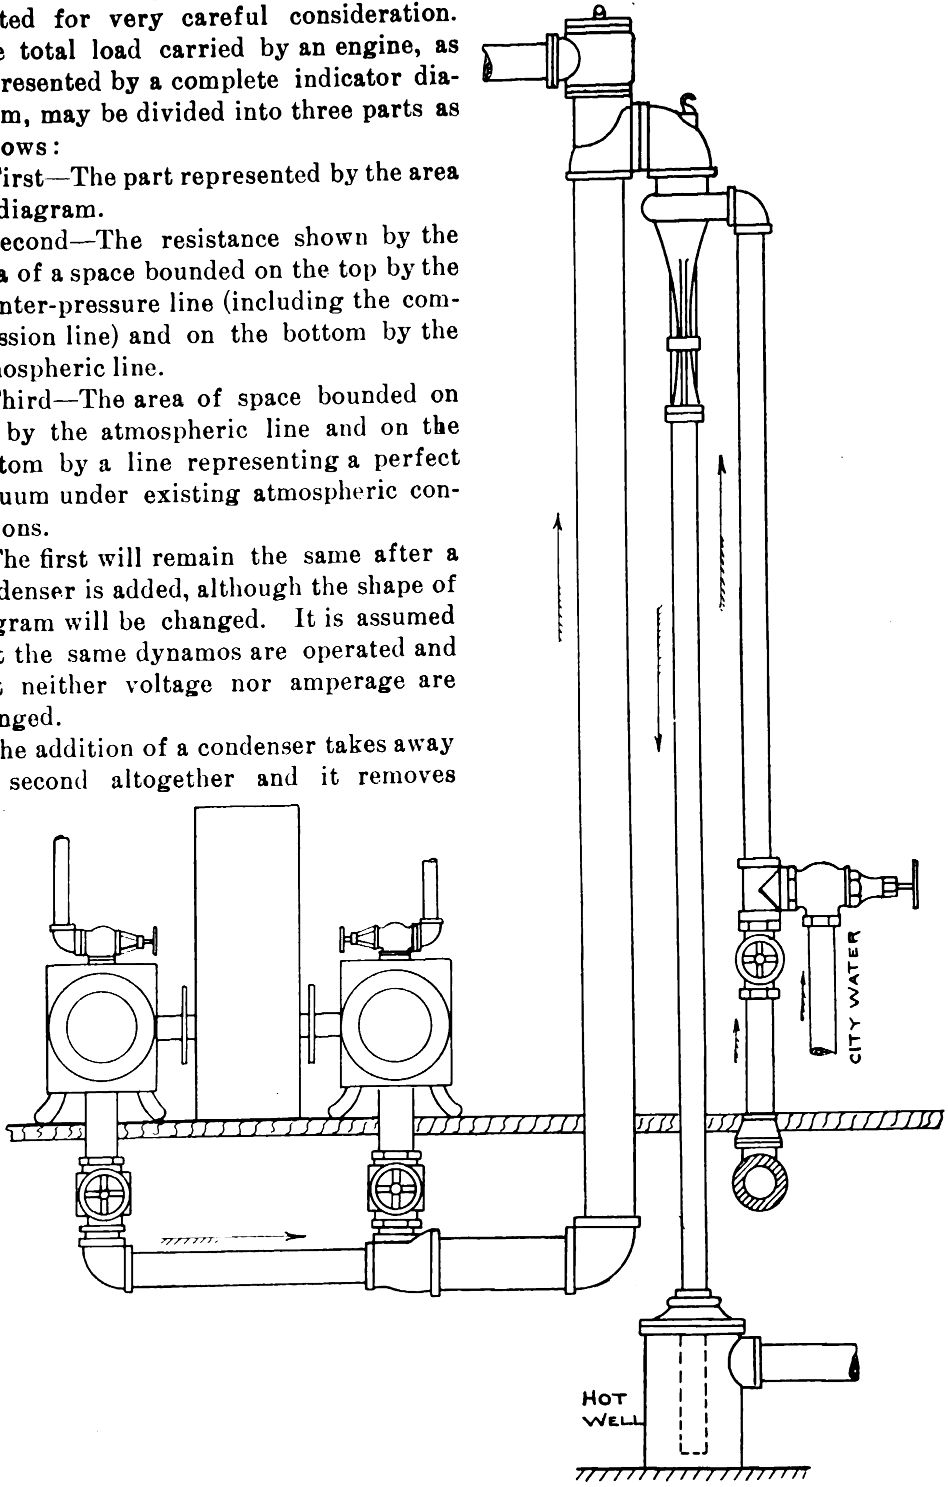

FIG. 7.

pounds, and as there are two cylinders it will develop power as follows:

$$\frac{314 \times 2 \times 53 \times 630}{33,000} = 635 \text{ hp.}$$

By advancing the cut-off to one-quarter stroke and assuming a back pressure of 3 pounds absolute the mean effective pressure is raised to 71.59 pounds and under these conditions (which are practical) the double condensing engine will develop 858 hp. This increase of power developed is due entirely to the addition of more dynamos or generators.

As the power in an electric station is usually stated in watts, which are reduced to kilowatts for convenience, as the prefix "kilo" means 1,000, an illustration of the calculation necessary to reduce horse power to kilowatts will not be out of place.

When calculating the power sent out, or developed by a dynamo, the amperes are multiplied by the volts and when the product is divided by 746 the quotient is the horse power developed, because 746 watts are equal to one electrical horse power. The term "electrical horse power" is used not because it differs from the steam horse power, for it does not, but as a matter of convenience when using it in connection with electricity.

As this engine is capable of developing 858 hp. it is equal to 858 × 746 = 640,068 watts, and dividing this by 1,000 shows that it amounts to 640 kilowatts.

However, this is on the basis of indicated horse power, and between the steam cylinders where pressure is secured and where dynamos send out current there is the friction of engine, shafting and dynamos. This will probably be not less than 20 per cent., or 640 × .20 = 128 kilowatts. Subtracting this from the total, shows that the actual output is reduced to 640 — 128 = 512, or, say, 500 kilowatts in round numbers. In other words, this engine is capable of driving ten generators of 50 kilowatts each, as shown in Fig. 5.

This load is too heavy for continuous service but it can be carried if required for a part of the night. As some of the lights are nearly always turned off about 10 o'clock in the evening, the reduction so secured will lighten the load enough to prevent heating of the machinery.

The Pennsylvania Tunnel.

(From the Philadelphia Ledger.)

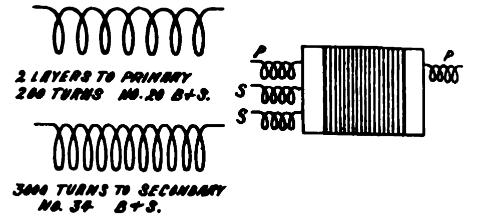
Among the interesting facts about the new Pennsylvania Railroad tunnel and terminal in New York are these: Total cost, $60,000,000, in addition to the $10,000,000 for the station site, on which were about 300 dwellings; daily train capacity, 900; passenger accommodation daily, 200,000; men at work, about 10,000; time required for trip under the Hudson, two minutes. In projecting this enterprise the engineers believe they have solved all the problems which baffled the most daring engineers of 23 years ago.

ELECTRICITY LEAFLETS.

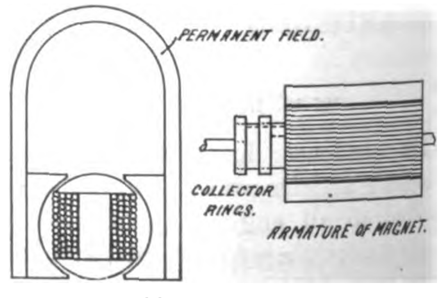
BY NEWTON HARRISON, E. E.

THE TELEPHONE.

The Induction Coil.—The success of a telephone system depends upon the employment of the induction coil, by means of which the pressure of the outgoing current is raised above that of the transmitter and its character changed into an undulating or alternating wave of electricity. The principle of its action is based upon the simple proposition of placing two coils in juxtaposition; one carrying the current which is directly employed, and the other the current resulting from this arrangement. Dr. Elisha Gray first introduced this idea in telephony, the object being to avoid the necessity of using a too powerful current in the transmitter and line. The transmitter, it is to be remembered, is used in series with a low pressure current, proceeding from either a primary battery or a dynamotor charging a storage battery. If the same current which is utilized for this purpose is also employed over the line then it would have to be capable of carrying that far. A current of this strength, and by this is meant both voltage and amperage, would be injurious to the transmitter and even then this would not possess the effectiveness of one produced by means of an induction coil. The current passing through a transmitter is always of one direction, simply varying slightly in strength with the variations in pressure in the transmitter. The current which will prove most satisfactory in a receiver is an alternating current. Therefore the transmitter current in the original form absolutely requires modification. To effect this modification of a unidirectional current into an alterating current at one time threatened to be a very difficult problem, but the introduction of the induction coil was the means of easily and inexpensively bringing about the transformation. The current entering the transmitter also passes through a coil of wire consisting of about 200 turns of No. 20 B. & S. gauge wound in two layers before completing its circuit. Around this first or primary coil is wound another or secondary coil which in its turn consists of about 1,500 turns of No. 34 wire wound in a double layer, that is, two wires side by side. This winding is therefore about 3,000 turns in all when they are connected in series or 1,500 double turns in multiple. The result of this juxtaposition, as previously stated, of the windings, is to raise the electromotive force of the current higher in proportion to the ratio of the windings. If the primary coil has 200 turns and the secondary 3,000 turns, then the ratio would be 3,000 to 200 or 15 times the pressure in the secondary as compared with the primary current. The changes in the transmitter are correspondingly magnified, with the result that the general effectiveness of the system is enhanced to an extraordinary degree.



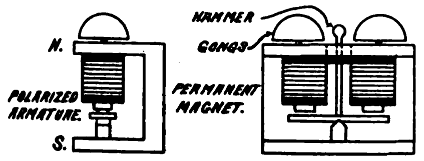
THE INDUCTION COIL.



THE MAGNETO.

The Magneto Generator.—Although the telephone system in Greater New York dispenses with the necessity of employing a magneto for ringing up a subscriber still the magneto call bell is required for signaling from the exchange itself to a subscriber. The subscriber, let it be understood, by this method signals "central" by merely lifting the receiver off the switchhook, though "central" signals by ringing the subscribers' bells. The employment of the magneto-generator has been the means of saving an enormous amount of possible trouble in the development of the signaling end of the telephone system in general use. A magneto generator is a dynamo having an armature wound with many turns of fine wire which produces and delivers an alternating current, and is in addition provided with fields or magnets which are "permanent." Thus the construction is as follows: A field of steel magnets, and a shuttle armature of soft iron wound with many turns of fine wire and collector rings or their equivalent for the conduction of the current. These devices are constructed so as to ring through 1,000, 5,000, 10,000 or even 50,000 ohms of resistance. It is therefore easy to estimate the value of this machine; of such simple and cheap construction; always ready to produce an alternating electric current with a few turns of the handle and able to ring through high resistances with comparative ease. The current when entering a call bell used in signaling is the means of causing a systematic tingle of a very vigorous character. This illustrates the difference between the generator and the call bell attachment, though both are generally found together in the so-called magnetos for telephone service.

The Call Bell.—The peculiarity of this device lies in the fact of its being partly magnetized. The armature and cores are so situated with respect to each other that when an alternating current passes through the coils of the magnets the armature is attracted and repelled and the bell hammer thereby strikes the two small gongs violently back and forth. The attraction and repulsion are the result of a permanent magnet being utilized to act both as a support for the magnet cores and a pivot for the armature. The two cores are thus magnetized by one pole and the swinging armature by the other. It is a simple matter to realize that an alternating current will be the means, by magnetizing these cores through their windings, to alternately weaken and strengthen their polarities respectively, of causing the armature to oscillate rapidly and thus to ring the bells by the hammer attached to it. Each of these devices represent more than they appear to be at first glance. It cannot be said that any one man was capable of originating and perfecting telephony to its present stage of excellence. On the contrary, each piece of mechanism was in some respects almost the life study of a group of scientists and inventors, their co-operation as it were being the foundation of all present successes.



Call Bell Construction.

Parts of a Telephone System.—A telephone system, theoretically, consists of a very simple combination of parts; a receiver at each end and a connecting line, but in practice more than this is required. Among a few of the important adjuncts, some of which have been noted, may be mentioned—

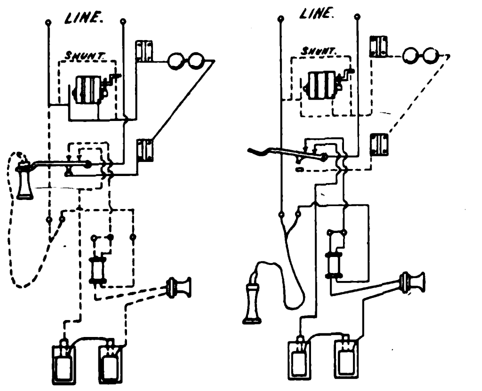
For transmission—the induction coil.

For speaking—the battery and the transmitter.

For hearing—the receiver.

For signaling—The call bell and the magneto.

The device, which represents only a connecting link between the two important parts of a telephone system, namely, the speaking and signaling circuits, is called the switch hook or hook switch. This is an automatic device by means of which the receiver when in use cuts out the signaling circuits and when not in use, by resting on the hook, throws them into circuit again. This idea is well represented in the illustration where the working plan is shown. The final resting place of the switch downward through the weight of the receiver cuts out the speaking circuit, composed of the battery, transmitter and primary of the induction coil. When the receiver is removed the switch hook cuts out the circuit composing the magneto and call bell; this, as is well known, being only done when the transmitter is to be employed and the receiver is held against the ear.



Station Circuits, Showing Switchhook.

Shunting the Magneto.—If the current entering the subscriber's call bell from a distance had to traverse the winding of the magneto armature, it would be weakened to a point that would probably render it useless. To avoid this difficulty a shunt or side path for the current is supplied wherever a hand magneto is used for signaling. This, in one of its simplest forms, consists of a round box-like device attached to the shaft. It is partly filled with small pieces of metal which are normally at rest, as shown, and thus provide a path for the incoming current which cuts out the magneto. When the magneto-handle is turned, however, the small metal pieces fly away through centrifugal force and break the shunt circuit otherwise formed by their being at rest. When they are at rest, the armature is, so to speak, short-circuited by them; when they are thrown against the sides of the box, the magneto is restored to its normal condition, and may be used for signaling.

Telephone Systems.—The telephone systems in vogue may be classified in various ways. Perhaps the most practical would be that of separating them into three general divisions as follows:

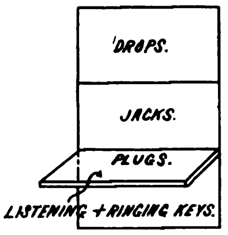
First—The party line and intercommunicating system.

Second—The central station, central exchange system.

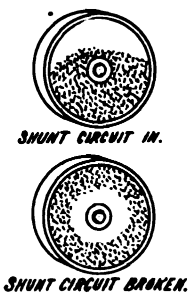
Third—The automatic central station system, or automatic exchange.

The intercommunicating system is of great service where the number of telephones is not too great. It finds its best application in hotels, factories and houses employing many 'phones. By this system of telephoning, any one in the system may be reached and spoken to readily, and is generally accomplished by means of a specially constructed switch. The party line or common circuit system is open to objections, among which the chief one might be regarded as lack of privacy. The central station system is by far the most important, and therefore calls for first consideration in the art of telephony.

The Central Station and its Switchboard.—Where more than 20 or 30 subscribers are dependent upon a telephone system for the purpose of exchanging remarks for business or social purposes, any other than a switchboard system, or at least a system employing a switchboard is out of the question. The central station or "exchange" system like everything else exists because it is the fittest to survive in the inventive and competitive struggle for first place. In barest detail it consists of a switchboard so equipped that two subscribers may be readily placed in communication with each other when one "rings up" and asks for the other. This apparently simple process is accomplished by means of a switchboard whose devices are adapted to this purpose and may be classified under the following heads:



Principle of the Telephone Switchhook.



Magneto Shunt.

1. For notifying "central"—Drops are employed.

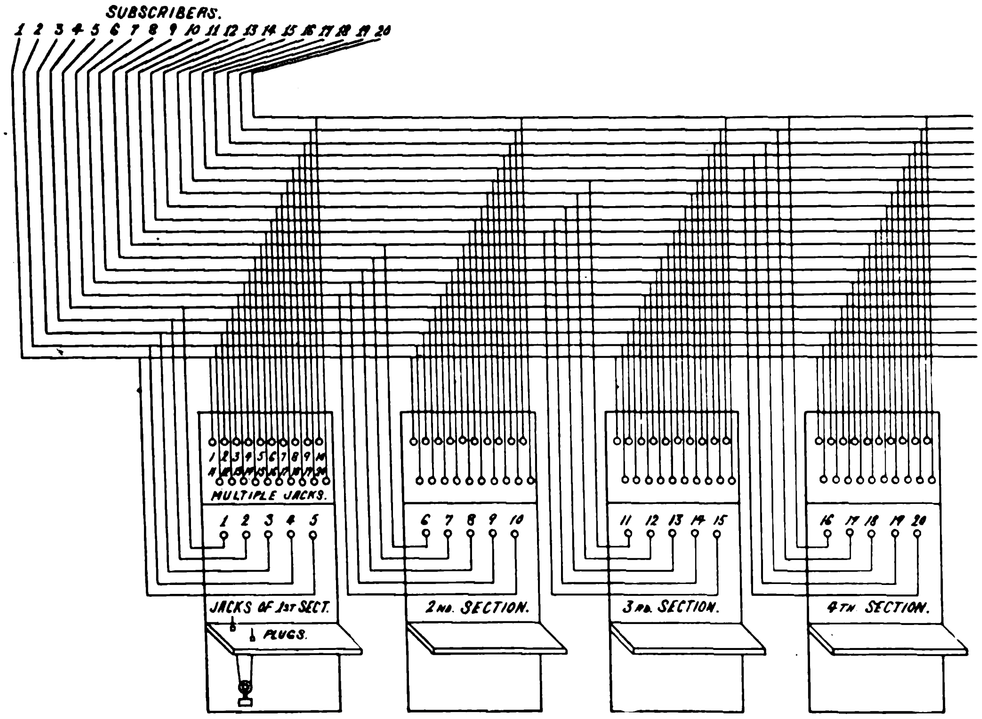
2. For connecting subscribers—Spring jacks are in use.

3. For line terminals of subscribers—Plugs with flexible cords are in service.

4. For listening and ringing up subscribers—Keys or switches are used.

The switchboard is so constructed that the operator or "central" can readily see and manipulate at the same time. The drops occupy the upper portion of the switchboard, as shown, and may run up in numbers corresponding to the number of subscribers' wires. Beneath these drops are the spring jacks, then on the horizontal portion of the switchboard are the plugs and keys, as indicated.

The Multiple Switchboard—The switchboards in use for city subscribers are necessarily very large and complicated. The smaller switchboard, serviceable for 50, 100, 200 or 300 subscribers, would not be great enough to cope with subscribers running into the thousands. Confusion and consequent delay would be the certain cause of failure in telephone service if allowed to exist. The operators are therefore given a certain number of subscribers apiece to take care of, with the means as well, in the switchboard construction, of connecting them to any other subscriber who is attached to the same board. Thus the labor is subdivided without any resulting delay or confusion, and each operator only takes care of 100 or 200 subscribers.



PRINCIPLE OF THE MULTIPLE SWITCHBOARD.

Principle of the Multiple Switchboard.—If a number of small switchboards were employed, and an operator with such a switchboard desired to connect a subscriber to another on a switchboard at the other end of the room, difficulty would naturally result of a most disagreeable character. To obviate this the subscribers are grouped into sections, and their lines brought to one large multiple switchboard, in which not only are the subscribers' lines in each section of easy access to the operator, but the connection permits the operators to connect the subscribers of the section in their individual charge to any other on the switchboard. This idea is shown in principle in the illustration where the employment of local jacks simplifies the proposition. Here the jacks of all subscribers on the multiple board are found in each section of the board. Each operator can therefore connect a subscriber with the utmost readiness with whosoever they may desire. In a multiple board, consisting of 4 sections of 5 subscribers apiece, if the operator in charge of section No. 1 ranges from 1 to 5, and No. 2 from 6 to 10, then they can manipulate as follows:

Operator No. 1 from 1 to 5, and to anyone from 1 to 20.

Operator No. 2 from 6 to 10 and to anyone from 1 to 20.

Operator No. 3 from 11 to 15, and to anyone from 1 to 20.

Operator No. 4 from 16 to 20, and to anyone from 1 to 20.

Following the diagram will clearly show the meaning of this important principle in multiple switchboards.

◆

Manila's Electric System.

The horse car system has been abolished in Manila and last week an up-to-date electric system was put in operation. Owing to climatic conditions, all the rails were painted with asphaltum. The destructive "white ant" exists in such large numbers that it was necessary to use teak for ties and sleepers. The rolling stock consists of 100 cars especially designed. The power plant is on an island in the center of the Pasig River and has a generating power sufficient to supply 500 arc lights, 30,000 incandescents, and current necessary for operating 100 cars over 40 miles of track.

◆

ENGLISH ELECTRICAL NOTES.

(From our London Correspondent.)

Electricity in Mines and Collieries.

During the past six months and more English electrical engineers, more particularly those who have specialized in the direction of mining installation work, have been very closely following the discussions which have been centering around the new Government rules and regulations relating to the equipment and operation of electric light and power plants in mines. The original draft was placed before colliery authorities and others for their comment and criticism with a view where necessary to emendations being effected before they came into force. We understand that the conditions are now about to come into operation, and in some quarters the view is expressed that they will lead to greater progress in English electric mining applications because they will make far safer and more efficient working. One inevitable result of the recent Governmental attention to the subject has been the further awakening of the English colliery owner and manager to the advantages accruing from electrical working under most conditions. There are distinct signs of important development just now. Much prejudice against electricity has been cleared away.

Quite naturally the new regulations have been the subject of discussions and papers at some of the provincial sections of the Institution of Electrical Engineers, and also at meetings of mining and engineering societies. Several of the papers prepared for these occasions by experts, have given much information relating to work done in different countries and the satisfactory economical results obtained. Practical data thus recorded have served the two-fold purpose of educating electrical engineers and convincing and converting mining officials. On March 28 a useful paper was read at Manchester by Mr. M. B. Mountain, M.I.E.E. Some mention was made of the work accomplished in the British Colonies, and in this connection, perhaps one of the finest installations in the world is that operating at the De Beers and Kimberley Mines.

At De Beers electrical working is used almost exclusively, and the installation is continually extending. The plant in 1903 had an output of 4,000 hp. steam turbines coupled direct to alternators being in use. Current is generated at 5,000 volts and distributed throughout the mines for working all classes of machinery and for hauling trains of trucks. Tables of performances of different types of coal cutting machines were among the statistical data prepared by Mr. Mountain.

Electrical Properties of Radio-active Substances.

Prof. J. J. Thomson has just concluded a series of three most interesting lectures on this subject before the Royal Institution in London. The chief conspicuous property of these substances was shown to be that of making the air around them a conductor of electricity. The behavior of a gas that was being ionized at a definite rate was described, it being pointed out that the number of electrified particles cannot increase indefinitely because destruction proceeds simultaneously with production, in consequence of the union of positively and negatively electrified particles to form non-electrified wholes. The saturation current was declared to be extremely important in the study of radio-active substances, because it represents a perfectly definite quantity and its measurement constitutes the most delicate method of detecting a radio-active substance. Prof. Thomson described the different kinds of radiation given out by radio-active bodies and said that the rays most recently detected were distinguished by want of penetrating power; they could only get through a few millimeters of air at ordinary pressures, whereas some of the other rays, which were unaffected by the strongest magnetic and electric fields, and were analogous to the Roentgen rays, could pass through six inches of solid lead. The new rays were detected by Prof. Thomson while he was trying to collect the electricity of the a rays which have been known for some time and which were positively charged and in mass were equal to nearly twice the hydrogen atom. It was found, said Prof. Thomson, that in an apparatus which should have indicated the presence of positive electricity, negative electricity was abundant; the cause of this was traced down to the fact that the radio-active body employed in his experiment was pouring out an immense stream of particles which were negatively charged but comparatively slow moving. Thorium and radium in particular are always giving off radio-active gas. In the case of thorium the gas rapidly loses its activity, the activity diminishing by one-half in the course of a minute, but radium takes four days to fall to half its value. The celebrated lecturer remarked that though radium was so very costly it seemed to be one of the most common elements. He had traced it in Cambridge tap water, in wheaten flour and so on. A radium atom he said lived for 800 years.

Among the many interesting things said by Prof. Thomson in the course of his entrancing lectures, was one relating to the stage at which radium showed its peculiar properties. These, he said, were only apparent at the end of its career, after persisting unchanged for centuries. This, he is reported to have said, "was a warning against assuming too hastily that because a phenomenon, such as the rising of the sun, had happened an indefinite number of times in the past, it was therefore going to continue indefinitely in the future. A spinning top might be made big enough to maintain its stability for days, but there came a time when a critical value was reached below which equilibrium could not persist. The case of radium was analogous."

THE FLEMING CYMOMETER.

The London Physical Society has recently had the pleasure of listening to Prof. J. A. Fleming, F.R.S., read a paper on the application of the cymometer to the "Measurement of Co-efficiencies of Coupling of Oscillation Transformers." The cymometer is an invention of Prof. Fleming's, by means of which the frequency of electrical oscillations can be measured as well as the length of electric waves. The present method is largely one of calculation; by means of which the number of oscillations per second, such as would proceed from a condenser for instance, are obtained from a knowledge of the values of the resistance, self-induction and capacity of the condenser and its circuits. When the number of oscillations per second are obtained, and they may range from one million to many millions per second, the length of a wave is obtained by dividing the speed of light, 192,000 miles per second by the number of oscillations in the same period of time.

For instance, if calculation shows that 192,000 waves are projected by a static discharge per second, the length of each wave would equal 192,000 miles divided by 192,000 waves, giving one mile as the length of each wave.

The cymometer consists of a sliding tubular condenser having two brass tubes separated by a thin ebonite tube, the outer tube capable of sliding off the inner tube. Parallel with this sliding condenser is placed an inductance coil or helix of bare copper wire wound on an ebonite tube. The outer brass tube of the sliding condenser carries a collar, which in turn carries a rod with a crutch at the end resting upon the inductance coil. The circuit of the instrument is completed by a copper bar, which joins one end of the inductance coil with the inner surface of the sliding condenser. When the outer tube of the condenser is moved by an insulating handle, the same motion reduces equally the capacity of the condenser and the position of the inductance coil included in the closed circuit. The circuit therefore consists of a variable capacity and inductance in series.

Prof. Fleming calls the square root of the product of the capacity and inductance in any position, the oscillation constant of the instrument. A scale is provided parallel with the inductance coil on which is engraved the oscillation constant and the corresponding frequencies. The formula generally given for a particular self-induction and capacity is that the frequency in waves thus resulting is equal to 1 ÷ (2 × 3.1416 × the square root of the product of the capacity and inductance.) The cymometer is also provided with a vacuum tube, preferably a Neon vacuum, which is connected between the inner and outer surfaces of the condenser.

The copper bar is placed parallel and near to a circuit in which oscillations are taking place and the handle of the instrument is moved, thus varying the oscillation constant, until the vacuum tube glows most brightly. Under these circumstances, it is known that the circuit of the cymometer is in resonance with that of the circuit being tested and their oscillation constants are therefore the same, hence the scale reading gives the product of the capacity and inductance of the circuit being tested. The instrument is also provided with a rectangular wire circuit the inductance of which is known. If this circuit is joined up with any unknown capacity and oscillations set up in it, the cymometer can be used as above, to determine the product of capacity and inductance in the circuit being tested, and the inductance being known, the capacity is therefore known also. Again, if we have any oscillation transformer, we can join up the primary and secondary circuits so as to inductively oppose or aid one another.

The inductance of any circuit can be

obtained for the high frequency currents by the cymometer in the following manner: The circuit to be tested is joined up in series with a known capacity and the rectangular circuit provided with the instrument. Two measurements are then made—first, when the inductance to be tested is included in the circuit; and second, when excluded from it. If the oscillation constants in both these cases are obtained, then the inductance will be equal to the oscillation constant of the first test minus the oscillation constant of the second test divided by the capacity, or

$$\text{Inductance} = \frac{\text{1st oscillation constant} - \text{2d oscillation constant}}{\text{capacity}}$$

The cymometer is particularly applicable to the measurement of the oscillation constant of a wireless telegraph aerial. The frequency in an open oscillating circuit and the length of ether wave resulting would be a valuable accomplishment from a direct practical standpoint. The frequency and length of wave received at a distant receiving point would also add greatly to knowledge required on the subject if measured, as claimed, with sufficient accuracy.

As regards the coefficient of coupling and the respective energies of the two rates of oscillation Prof. Fleming said he had not given sufficient attention to the theoretical side of the subject to be able to furnish expressions for the energies of the two oscillations.

In connection with wireless telegraphy and the antennæ or aerial employed, Prof. Fleming stated that if the mutual induction between the aerial wire and the cymometer were small, as it was in the case of the instrument exhibited, then the cymometer only detected the oscillations which existed in the aerial. There was no creation of duplicate oscillations in and by the cymometer itself.

The change in the dielectric capacity of such insulating materials as rubber and glass were discussed by Prof. Fleming in answer to a question asked; and he stated that rubber or ebonite was chosen in place of glass because in this material the change in this respect could not be detected with varying frequencies.

In glass the strange fact is presented, that under the varying stress of frequency the dielectric quality of it changes. To remove such possibilities in his apparatus, the only material reliable enough to give the element of accuracy required was ebonite. Thus the general nature of the application of Prof. Fleming's device as thus reviewed, is that of readily discovering the frequency and length of long electric waves. This is possible by means of an inductance and capacity that is adjustable. When adjusted and a certain degree of resonance is established the little Neon tube will glow. By this indication it is known that the circuit undergoing examination, and the cymometer are in tune electrically with each other. The immense advantage obtained by this device by those experimenting in the field of wireless telegraphy and telephony or to those conducting scientific experiments can very well be imagined.

With a definite knowledge of frequency and wave length during all experiments and tests, it seems that the striving after syntonic telegraphy will rapidly approach a successful issue. Sympathetic systems, which, unless awakened to action and response by a certain frequency, are inoperative, and thereby preserve the privacy so necessary to practical success, will now be tuned with accuracy. The cymometer is thus of peculiar value at this particular period in the development of wireless methods as in all probability time will so readily testify.

The Magnetic Club Dinner.

The Magnetic Club held its annual spring dinner on Thursday evening last, in the ballroom of the Hotel Astor of this city. Seated at the table with Col. A. B. Chandler, president of the club, were Thomas A. Edison, Clarence H. Mackay, Col. Robert C. Clowry, P. V. De Graw, Frederick P. Fish, U. N. Bethell and Patrick J. Murphy.

Never before, it was remarked, had the men practically in control of the electrical communications over the larger part of this continent and under the seas West and East met on an occasion of like character, and in this respect at least, the dinner was unique, attended as it was by about 220 of the most prominent and active telegraphers and other workers in the local electrical field. Although the Magnetic Club has four dinners a year, the spring dinner is the eventful one of the four.

When Colonel Chandler introduced the after-dinner period with a brief speech he was greeted at intervals with the clicking of telegraph instruments, the sound of the phonograph and the ringing of telephone bells.

If Mr. Edison, who had sat immobile on the right of Colonel Chandler, never before had been stirred from his well known passiveness, he plainly showed himself moved at the interpolations which had been carefully prearranged. When Colonel Chandler referred to the telegraph the company, led by a pianist and soloist, sang to the air of "My Grandfather's Clock" an original verse and chorus.

The dramatic event of the night was in connection with Colonel Chandler's comment on the electric light. Then the electric lights in the banquet hall were switched off and in the mellow glow of shaded light from the banquet candles the company sang "It Was Just Like This in the Olden Days." When the current was switched on and the diners arose and cheered Mr. Edison to the echo he, too, stood and bowed, the applause continuing after the famous inventor resumed his seat.

Other speakers, who were entirely informal in their remarks, no toast programme having been arranged, were Mr. De Graw, Mr. Fish, Mr. Van Wormer, Mr. Estabrook and Mr. Murphy.

Bids Wanted for Government Electrical Supplies.

The Bureau of Supplies and Accounts of the Navy Department is inviting sealed proposals until May 2 for furnishing Eastern navy yards with the following material: Schedule 161, panel boards, cable, wire, electrical supplies; schedule 162, cable, annunciators; schedule 164, cable; schedule 165, electrical supplies. Blank proposals will be furnished on application to the Navy Pay Office in New York or to the Bureau. Applicants should designate by number the schedules desired.

On May 9 the Bureau will open bids for furnishing the Naval Home in Philadelphia with electrical supplies during the next fiscal year. Blank proposals may be obtained on application to the Navy Pay Office in Philadelphia or to the Bureau of Supplies in Washington. The schedule number is 168.

The War Department, through the Signal Office, is inviting sealed proposals until May 11 for furnishing the Signal Corps with 10-drop telephone switchboards, according to specification No. 282, in lots of 10 and 20. Prices to hold good until June 30, 1906. Further information will be furnished on application to Gen. A. W. Greely, chief signal officer, Washington, D. C.

The Secretary of Agriculture is inviting sealed proposals until May 10 for furnishing and laying for the Weather Bureau 35 statute miles of one-conductor telegraph cable between Charlevoix and Beaver Island, Mich. Blanks and information for bidding may be obtained from the Chief of Weather Bureau, Washington, D. C.

Col. Charles S. Bromwell, in charge of

public buildings and grounds, Washington, D. C., is inviting sealed proposals until May 10 for furnishing electric battery supplies during the next fiscal year.

American Institute of Electrical Engineers.

The annual business meeting of the American Institute of Electrical Engineers will be held in New York City, Tuesday, May 16, at which the reports of the board of directors and the treasurer will be presented.

A Bargain in Motors.

Our readers are requested to take notice that a great bargain sale in motors will be held by Charles Shongood on April 26, 1905, at 10:30 A.M., at 113 Leonard street, New York City. These machines are of exceptional quality and are adapted to small power purposes and sewing machine service. The number of complete motors is 250 and in addition about 250 fields and many armatures will be sold. Business misfortunes on the part of the manufacturer have led to this opportunity. In addition to the above, several hundred electric sewing machine stands complete and others unassembled will be sold. The property may be inspected at any time before the sale and further particulars can be had on application.

A New Electric Clutch.

The Williams Electric Machine Company, of Akron, O., has recently brought out a new and improved electro-magnetic clutch, the invention of Mr. H. A. Williams. This clutch is the result of years of experimenting and is fully covered by 18 United States patents. The clutch is of the friction disk type, one-half of the disks being mounted on the driving, and one-half on the driven. These disks are interleaved and are a part of the magnetic circuit. When the current is thrown on the magnetic coil the moving member of the clutch compresses the disk which by their friction one with the other, take up the load similar to the operation of the well known mechanically operated fric-disk clutch that have long been on the market and which have been a decided success. A catalogue descriptive of this clutch may be had by addressing the company as above.

Entertaining and Interesting Publicity.

The New York Central's "Four-Track Series" has for 15 years been a recognized feature in railway advertising, and one which has been made so general as to include, directly or indirectly, scores of industrial and other American enterprises which are of interest not only to all citizens of this republic but also command the attention of our British and European cousins, and our brothers and cousins in the Far East. No. 38 of the "Four-Track Series" has just been issued and is a comprehensive presentation of the general information bureaus and city ticket offices of the New York Central lines in America and in Europe. It is beautifully printed and contains 82 illustrations. A copy will be sent, postpaid, on receipt of a two-cent stamp, by George H. Daniels, General Passenger Agent, New York Central Railroad, Grand Central Station, New York.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED APRIL 11, 1905.

Electric Railways and Appliances.

786,795. Trolley-Wheel. Edwin W. Clark, Columbus, Ga. Filed July 28, 1904.

786,832. Trolley-Wire Guide. Stewart P. McMullen, Sioux City, Ia. Filed June 4, 1904.

786,887. Trolley Device. Anton F. Flierboom, Elizabeth, N. J., assignor of one-half to John F. Conrad and William R. Bonnell, same place. Filed Jan. 28, 1905.

786,894. Railway Signal. Orlando W. Hart, Fall River, Mass. Filed Aug. 14, 1901.

787,033-034-035-036. Trolley-Stand. Boniface A. Grasberger, Richmond, Va. Original application filed Jan. 23, 1904. Last application filed Jan. 20, 1905.

787,169. Trolley Catcher and Retriever. Charles E. Gierding, Newark, N. J. Filed July 7, 1904.

787,343. Wire-Replacer for Trolleys. William Peck, Steubenville, O., assignor of one-half to W. W. Harper, Toronto, O. Filed Dec. 13, 1904.

Electric Lights and Appliances

787,043. Electric-Arc Lamp. Bruno Jackisch, Charlottenburg, Germany, assignor to the firm of Allgemeine Beleuchtungs und Heiz Industrie Actien Gesellschaft, Berlin, Germany. Filed Sept. 23, 1904.

787,338. Rosette or Receptacle for Conduits for Electric Wires. George A. Lutz, New York City, assignor, by mesne assignments, of one-half to Frank K. Boland, same place. Filed May 23, 1901. Renewed June 5, 1903.

Electrical Machinery and Apparatus

786,797. Electrical Stop-Motion. George B. Cocker, Frankford, Pa. Filed Nov. 20, 1903.

786,823. Electricity-Meter. Friedrich Lux, Heidelberg, Germany. Filed Nov. 29, 1902.

786,907. Electric Time Relay-Switch. William W. Lackie, William T. Calderwood and William H. D. MacEwen, Glasgow, Scotland. Filed April 26, 1904.

786,918. Continuous-Current Electric Motor. Henri Pecheur, Paris, France, assignor to the Societe Anonyme pour le Travail Electrique des Metaux, same place. Filed Jan. 6, 1905.

786,939. Transmission Gear. Gilbert R. Albaugh, Cleveland, O., assignor, by mesne assignments, to the Olds Motor Works, Detroit, Mich. Filed Dec. 15, 1902.

786,955. Emergency Brake-Valve. Fred B. Corey, Schenectady, N. Y., assignor to the General Electric Company. Filed Aug. 15, 1904.

787,027. Monophase and Polyphase Alternating-Current Machine. Michael von Dolivo-Dobrowolsky, Berlin, Germany. Filed May 18, 1903.

787,096. Power-Transmission for Motor-Vehicles. Stephen H. Hanson, Akron, O. Filed May 10, 1904.

787,147. Lock for Electric Switches. Charles L Buschmann, Indianapolis, Ind. Filed Feb. 20, 1903.

787,184. Dynamo. Edward B. Jacobson, Pittsfield, Mass., assignor to the Pittsfield Spark Coil Company. Filed Jan. 27, 1904.

787,187. Electric Time-Switch. Robert D. Jones, San Antonio, Tex. Filed Oct. 1, 1903.

787,227. Electric-Motor System. Charles P. Steinmetz, Schenectady, N. Y., assignor to the General Electric Company. Filed Oct. 5, 1903.

787,256. Direct-Current Meter. James S. Anthony, New York City, assignor to the General Electric Company. Filed Aug. 15, 1902.

787,292. Dynamo-Electric Machine. Tracy B. Hatch, Los Angeles, Cal. Filed March 7, 1904.

787,303. Alternating-Current Series Motor. Marius C. A. Latour, Paris, France, assignor to the General Electric Company. Filed Aug. 30, 1904.

787,305 Alternating-Current Motor. Maurice Milch, Schenectady, N. Y., assignor to the General Electric Company. Filed Oct. 12, 1903.

787,336. Method of Operating Alternating-Current Motors. Waldo A. Layman, St. Louis, Mo. Original application filed Dec. 28, 1903. Divided and this application filed Sept. 3, 1904.

Telephones and Telephone Apparatus

786,901. Telephone-Exchange System. John C. Hubinger, Keokuk, Ia. Filed April 18, 1904.

786,925. Means for Signaling and Telephoning on Electric-Trolley or Other Systems. Charles R. Van Trump, Wilmington, Del. Filed Aug. 4, 1904.

787,107. Telegraph or Telephone Wire Insulator. Robert J. McDaniel and Salathiel V. Graves, McFall, Mo., assignors to Samuel I. Hudson, Watkins Mo. Filed Dec. 10, 1903.

787,113. Apparatus for Telephone-Exchange Systems. John G. Roberts, Chicago, Ill., assignor to the Western Electric Company. Filed Jan. 18, 1904

787,119. Desk-Telephone Bracket. Thomas Q. Scott, Baltimore, Md. Filed May 14, 1904.

787,120. Trunk-Line for Telephone-Exchanges. Charles E. Scribner, Chicago, and Frank R. McBerty, Downers Grove, Ill., assignors to the Western Electric Company. Filed April 23 1897.

787,307. Jointed Adjustable Support for Telephone Receivers. Edwin D. McLean, Marissa, Ill., assignor of one-fourth to William W. McLean, Pittsburg, Pa., and one fourth to Edward S. McLean and one-fourth to James M. McLean, Marissa, Ill. Filed Jan. 9, 1904.

Miscellaneous.

786,843. Electric Signaling System. William F. Robinson and Columbus F. Broadhurst, Kansas City, Mo. Filed Oct. 3, 1903.

786,111. Electric-Conduit Terminal. William J. Miles and Jesse Patterson, Buffalo, N. Y. Filed June 21, 1904.

786,912. Burglar Alarm. Charles O. Miller, Estherville, Ia., assignor to the Millers Electro-Pneumatic Burglar Alarm Company, same place. Filed April 9, 1903.

786,946. Means for Recovering Magnetic Iron from Ore-Seperating Tanks. Erastus S. Bennett, New York City. Filed Oct. 17, 1903.

787,005. Electric Recording Instrument. David J. Steele and Charles Kratt, Glasgow Scotland. Filed May 7, 1904.

787,012. System of Electrical Distribution. William A. Turbayne, Lancaster, N. Y., assignor to the Gould-Coupler Company, New York City. Filed June 24, 1904.

787,024. Means for Controlling the Charging of Storage Batteries. Rufus N. Chamberlain, Depew, N. Y., assignor to the Gould Storage Battery Company, New York City. Filed Feb. 8, 1904.

787,032 Rheostat. Fred E. Goodall, Chicago, Ill., assignor to the Hanson & Van Winkle Company. Filed Oct. 6, 1904.

787,047. Electric Resistance. Harry W. Leonard, Bronxville, N. Y. Filed Dec. 8, 1904.

787,057. Wireless Telegraph Transmitter. Harry Shoemaker, Jersey City, N. J., assignor to the International Telegraph Construction Company, New York City. Filed July 29, 1904.

787,089. Variable Resistance or Conductor for Electric Currents. William H. Fahrney, Chicago, Ill. Filed Jan. 10, 1903.

787,192. Means for Transforming Direct Current. Osias O. Kruh, Schenectady, N. Y., assignor to the General Electric Company. Filed Dec. 9, 1903. Renewed Sept. 1, 1904.

787,193. Frequency-Changer. Osias O. Kruh, Schenectady, N. Y., assignor to the General Electric Company. Filed Dec. 12, 1903. Renewed Sept. 1, 1904.

787,221. Electrolytic Method. Alexander S. Ramage, Detroit, Mich. Filed Jan. 31, 1905.

787,228. Means for Transforming Direct Current. Charles P. Steinmetz, Schenectady, N. Y., assignor to the General Electric Company. Filed Dec. 17, 1903. Renewed Sept. 1, 1904.

787,318. Electric Signal Device. Ludwig S. Walle, Brooklyn, N. Y., assignor to Fridtjof Jebsen, Bergen, Norway. Filed Dec 29, 1903.

787,319. Protective Device for Electric Apparatus. Leonard Wilson, Pittsfield, Mass., assignor to the Stanley Electric Manufacturing Company. Filed May 12, 1904.

THE TELEPHONE WORLD.

Bell Company's Listings in New York.

The American Telephone & Telegraph Company has had listed on the New York Stock Exchange, $10,000,000 additional 4 per cent collateral trust bonds of 1929 and $7,000 additional capital stock, making total amount of collateral trust bonds listed $38,000,000 and capital stock $131,551,400. The Stock Exchange committee recommends that it be empowered to add to the list from time to time, but prior to October 1, 1905, $15,000,000 additional collateral trust bonds, on official notification that they have been issued, according to the terms of application, making total amount authorized to be listed $53,000,000.

Progress of Independent System.

The Citizens' Telephone Company, with headquarters at Barton, Vt., is just five years old. Its manager, Mr. Buzzell, has promised lower rates and extended service. The system now extends from Barton to Woodsville and from West Concord to West Danville and is constantly expanding. It has connections with the People's Telephone Company with 900 'phones, and beyond that is the Canadian People's line with about 2,000 instruments. On the south Mr. Buzzell's system connects at Woodsville with the Woodsville Telephone Company, and at Bradford with the Bradford Telephone Company, and other Independent companies having several thousand patrons. In Orleans County connections are had with the Maguire line, which has over 400 patrons. Mr. Buzzell has been very successful in developing the farmers' lines, and he is beset on all sides to open up new territory. He is extending these lines as fast as possible.

William Busby, president of an Independent telephone company operating in South McAlester and Eufaula, I. T., recently said that "extensions and improvements are the order of the day in telephone business in Indian Territory. We are making preparations now to rebuild our line according to the most approved modern methods. Cheap lines and crude methods might have done in the earlier days, but with the amount of business which is now being done in Indian Territory, the demands upon a system have become fully as exacting as in many larger communities, which have not grown up in times of stress and strenuosity, as have those in the territory."

There is a rumor that there may, in the near future, be lower telephone rates in Pawtucket, R. I., as there is reported a prospect of another company appearing in the field, providing sufficient encouragement can be secured.

The Benson, Minn., Telephone Company has been reorganized as a stock company under the name of the Swift County Telephone Company. The old lines will be removed and replaced by a cable and about 100 miles of farmer lines built.

At Crookston, Minn., the Polk County Telephone Company, capitalized at $50,000, was lately incorporated by F. M. Slyter, C. D. Carter, J. D. Pettit and G. W. Hooper, all of Crookston.

Independents Combine.

At a recent meeting held in Peoria, Ill., one of the largest and most complete Independent telephone associations in the West was perfected. Nearly 100 delegates representing probably one-fourth as many companies, were present, and after formulating a constitution and by-laws, the following officers were elected:

G. H. Glass, Pekin, president; C. A. Camp, Henry, vice-president; Albert Schuler Streator, secretary; B. F. Wasson, treasurer; members of executive board, L. C. Schwerdtfeger, Lincoln; O. C. White, Princeton.

The object of the alliance is to perfect a thorough long distance service in order to successfully compete with the Bell Company.

According to officers of the new association, uniform toll rates fully 30 per cent. less than those formally maintained will be adopted.

Ask State for Help.

The resolution by Representative S. D. Peterson, of New Ulm, Minn., directing the attorney general to investigate the complaint of business men of Springfield, Minn., that unfair methods were used to destroy an Independent telephone line, was unanimously adopted a short time ago by the House.

The resolution alleges that a telephone system is maintaining a general store at Springfield, selling merchandise below cost, for the purpose of destroying the competition of Independent local rural lines and coercing the business men into patronizing the exchange and lines of the telephone system.

At a special stockholders' meeting of the Shaw, Wis., Telephone Company, a resolution was adopted amending the articles of incorporation of said company, increasing the capital stock from $5,000 to $15,000, as it was necessary to do this inasmuch as the original capital had all been used constructing the present lines. With this additional increase of capital the lines will be extended in different directions, into the towns of Brunswick, Drammen, Washington, Pleasant Valley and Clear Creek. It will only be a short time before the farmers of that section of Eau Claire County will be in direct communication with Eau Claire, Chippewa Falls and all long distance points.

E. de los Magee, an attorney, and Dr. Ferdinand Butterfield state that in the interests of a number of San Francisco Cal., and Eastern capitalists they will within the present month make application to the board of supervisors for a franchise with a view to operating a new telephone system in San Francisco.

Superintendent Rice Macauley, of the Seneca-Gorham, N. Y., Telephone Company, has announced that extensions of the line are to be made from Rushville and Middlesex to Bellona Station, to Lewis Station and Flint Creek and to Cottage City on Canandaigua Lake.

The Blanchardville & Hollandale Farmers' Telephone Company of Blanchardville, Wis., has increased its capital stock from $1,000 to $2,000.

Telephones on Target Range.

The work of installing a complete telephone system at the national target range, two miles north of Junction City, Kan., on the Fort Riley reservation, has been completed. Each firing point at the range is connected underground with the butts, where eight telephones will be in operation during the firing. These connections are so distributed that there are two for each set of seven targets, one in front and one in the rear. This system is to be connected with the Fort Riley system, so that it will be possible to talk from any 'phone at the firing points with the post or city. Civilian organizations of marksmen of the West will probably get to use the target range for their events this year and the years following.

J. B. Marquis, Jr., proprietor of the Marquis Telephone Company, of Norwich, N. Y., has purchased 5,000 feet of telephone cable, and will commence the work of installing the cable in the center of the village. The Marquis line, which was established in 1895, with only three 'phones, had a steady growth until in January, 1904, it had 417 'phones. The business has increased 50 per cent. during the past year and Mr. Marquis now has 620 subscribers, and a large Independent line. He has established working relations with other Independent lines, and about June 1 expects to make connections which will afford a through line from Utica to Elmira. After the cables have been installed a new and improved central energy system switchboard will be added to the equipment.

The two telephone companies operating in York, Pa., will ask city councils to grant franchises to construct and operate an underground conduit for their cables and wires. The companies are to give bonds in the sum of $2,000 to restore the streets.

The Winona, Minn., Telephone Company has elected James A. Tawney, John Dietze, Edward Lees, S. L. Wright and J. R. Mitchell as directors, and these have elected the following officers: President, James A. Tawney; vice-president, secretary and treasurer, John Dietze.

The Lake Shore & Michigan Southern and the Pittsburg & Erie Railroad Companies are using telephones with satisfactory results.

The Beaver Dam, O., Telephone Company, of Allen County, has increased its capital from $15,000 to $25,000.

Telephone Incorporations.

The Banner Telephone Company, East Grand Forks, Minn. Capital stock $25,000. Incorporators: Arney Grundysen, O. Osmunden, P. J. McCoy and B. Johnson.

The Streator Independent Telephone & Telegraph Company, Jersey City, N. J. Capital stock, $200,000. Incorporators: Charles N. King, Le Grand Bouker and John J. Reilly.

The Spring Lake & Red Creek Telephone Company, Westbury, N. Y. Capital stock, $1,000. Incorporators: Newton Douglas, Westbury; Benjamin W. Moth and George G. Wood, Red Creek.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Central City, Ky.—C. H. Blandford, city clerk, has sold at public auction to the highest bidder the franchises for electric light and a street railway. B. F. Creech was the purchaser of both franchises. The conditions under which the sale was made are that the electric light plant shall be completed in eight months, and the street railway in 18 months.

Detroit, Mich.—The articles of association of the Peninsular Electric Light Company have been amended so that it may acquire franchises other than those of the original company in other counties than Wayne.

Everett, Wash.—The Snohomish Electric Light & Power Company will extend its lighting system.

Fairmont, Minn.—The citizens have voted to issue bonds to the amount of $18,000 for the purpose of improving the electric light and waterworks systems.

Glasgow, Mo.—The Glasgow Electric Light, Power & Industrial Company, with a capital of $7,000, has been incorporated by W. R. De Witt, of this place, and George H. Milburn, of St. Louis.

Grand Forks, N. D.—The municipal election to vote on the issuance of bonds to the amount of $30,000 for the installation of an electric lighting plant was lately carried.

Henry, Ill.—The electric light plant has been sold by the Sterrerts to J. J. Crickenberger.

Horton, Kan.—The Rock Island Company is contemplating the erection of an electric lighting plant at its shops here.

La Porte, Ind.—Frank R. Northam has been appointed receiver for the Edwards Railroad Electric Light Company.

Lindsay, Neb.—This place is in a fair way to get an electric light plant. There is a fine water power close to town, and parties are now figuring on a dam, and the plant is almost assured.

Middleburg, Pa.—Electric light franchises have been granted in Sunbury, Selinsgrove and Middleburg to George W. Wagenseller, of this place, and David Goltstein, of Pittsburg. It is proposed to organize a company called the Middle Creek Electric Company, of which P. H. Harter, of Sunbury, is to be treasurer, and combine the local companies of the three places and also of Northumberland, to furnish electric light by means of a water power in Middle Creek, two miles below Selinsgrove, where a tunnel will be dug through Naishe's Mountain for a distance of 1,200 feet.

Mishawaka, Ind.—The Indiana & Michigan Electric Company is to be incorporated. The company will have a capital of $200,000,000, and will control over 60,000 electrical horse power generated by huge plants located along the St. Joseph River in this State and Michigan.

Mitchell, S. D.—The Mitchell Gas Company, which is represented by C. C. King, of Scotland, has purchased the electric light plant of this city from J. B. Mikesel.

Mount Hamilton, Cal.—The Lick Observatory is soon to have an electric light plant of its own established on Mount Hamilton.

Muscatine, Ia.—A new electric plant is proposed for this city.

Muskegon, Mich.—The ordinance granting to the Morton B. Wheeler Company a franchise to furnish electric light and power within limits of this city, was recently passed by the council.

Platteville, Wis.—The Platteville Electric Light & Power Company, with a capital of $20,000, will increase the same to $50,000. M. S. Sickle is president, and J. H. Evans secretary.

Richmond, Va.—Plans are being considered for the erection of the new electric lighting, heating and power plant for which the Legislature appropriated $75,000. Samuel W. Bigger, clerk of the capitol rebuilding committee, may be addressed.

Stamford, Conn.—The Rector Electric Light Company of this city has increased its capital stock from $50,000 to $150,000.

Vandalia, Ill.—The Dieckmann Electric & Improvement Company, with a capital of $110,000, has been incorporated here by George A. Dieckmann, J. R. Myers, J. F. Hibbitts and others, to operate a heat, light and power plant.

STREET RAILWAYS.

Athol, Mass.—A corporation with $80,000 capital, to build a trackless trolley system from this city to Barre by the way of Petersham, North Dana and Dana Center, is likely to be formed within a few weeks. John A. Carter, a well-to-do resident of Petersham, is the chief promoter, and others interested are J. S. Noble, of Springfield, and the Noble Milling Company.

Bryan, Tex.—Interested parties in this city have received advices from Austin of the filing in the office of the Secretary of State of the charter for the Bryan-College Electric Railway Right of Way Company. Messrs. N. H. Brown and F. S. Johnston, of College Station, and Messrs. A. W. Wilkerson, J. W. Bates and W. P. Connelly, of Bryan, are named as incorporators of the company.

Buffalo, N. Y.—the Lima, O., Electric Railway & Light Company, which was owned by local men, has been sold to a syndicate representing the Widener-Elkins interests. One of the former stockholders said that the purchase of the road by the syndicate is for ths purpose of completing a line between Lima and Toledo.

Columbus Junction, Ia.—A trolley line will be run from here through Louisa and Henry Counties to Mt. Pleasant.

Mount Vernon, Ind.—The city council has unanimously passed the electric street railway franchise as presented by W. P. Larcy and assigns of Evansville and Princeton granting the company the right to construct and operate an electric railway through the streets of this city.

New Martinsville, W. Va.—The right of way is now being taken for the electric railway which is to be built from here to Middlebourne.

Norwalk, O.—A new electric road from Mansfield to Greenwich, and thence to this city, is projected.

Richmond, Va.—A movement is on foot for an electric line running from the extreme lower end of Charles City County through Charles City and lower Henrico County into this city.

Spokane, Wash.—J. P. Fitch says an electric line will be run from this city to Lewistown, Mont.

Springfield, Mass.—The Springfield Street Railway Company, controlling all of the electric car traffic in this city, and operating 93¾ miles of track, passed into the control of the New York, New Haven & Hartford Railroad Company last week.

Sunbury, Pa.—A trolley line will be built from here to Mifflintown.

Zanesville, O.—Arrangements for constructing the Zanesville, Cambridge & Northern traction line are going forward rapidly.

POWER PLANTS.

Beallsville, O.—L. S. Whitehead, promoter of the Whitehead Electric Light & Power Company here, has filed notice with the recorders of Monroe, Belmont and Washington Counties to the effect that he has appropriated the waters of the Muskingum, Sunfish and Captina Creeks and their tributaries, to be harnessed and used in the manufacture of power for his plant, which will be constructed with the intention of supplying light and electric power throughout Belmont. Monroe and Washington Counties.

Harrison, O.—In order to furnish electric power for factories and other purposes, the citizens of this place propose to harness the Whitewater River.

BIDS WANTED.

Des Moines, Ia.—Sealed proposals will be received by J. W. Campbell and W. W. Wise, of the board of public works in this city, until April 26, for lighting the public parks of the city with electricity, for the term of 5 1-5th months from May 1, 1905. A certified check for $200 is required.

New York City.—The Bureau of Supplies and Accounts of the Navy Department is inviting sealed proposals until April 25 for furnishing Eastern Navy Yards with the following: Schedule 149, cable and electrical supplies. Blank proposals can be obtained at the Navy Pay Office in this city.

San Francisco, Cal.—On May 9 the Bureau will open bids for furnishing the Mare Island and Puget Sound Navy Yards with the following: Schedule 156, conduit, lamp cord, clusters, transformers and miscellaneous electrical supplies. Schedule 157, motors. Applications for blank proposals should designate by number the schedules desired. Blank proposals may be had at the Navy Pay Offices in this city and Seattle.

Washington, D. C.—Sealed proposals for furnishing the Government Printing Office with electrical supplies during the fiscal year 1906 will be received until May 4. Specifications and detailed information furnished on application to F. W. Palmer, public printer, this city. The District of Columbia commissioners are inviting sealed proposals until May 4 for furnishing the various branches of the government of the District with electrical supplies and material during the next fiscal year. Specifications and blank proposals will be furnished on application to the property clerk, District Building, Washington, D. C.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 15⅛@15¼c.; Lake 15¼@15⅜c.; casting, 14⅞@15c.

The Edison Electric Illuminating Company of Boston has declared the regular quarterly dividend of 2½ per cent., payable May 1.

President Winter of the Brooklyn Rapid Transit Company says there has been no alliance between his and any other company and none is in contemplation.

The directors of the United Traction Company of Albany and Troy, N. Y., have declared the regular quarterly dividend of 1¼ per cent.

The New York, New Haven & Hartford Railroad Company has purchased the Westfield (Mass.) Street Railway by buying an option on the stock between $160 and $175 per share.

The Havana (Cuba) Electric Railway Company's annual report shows a total surplus of $138,270 for the past year. The surplus for the previous year was only $545.

The Lowell (Mass.) Electric Light Corporation has declared a semi-annual dividend of $4 a share, payable May 1. Books close April 20.

The Butte (Mont.) Electric & Power Company has declared the regular quarterly dividend of 1¼ per cent. on its preferred stock, payable May 1 to holders of record April 27.

The Edison Company of Boston will give its stockholders no new stock rights this year, as its present capital is sufficient to care for its business for another year at least.

The Federal Telephone Company, whose most extensive operations have been in Allegheny County, Pa., is retiring from business and has communicated the fact to the East McKeesport Council.

Approximately 14,000 shares out of a total of 19,854 shares of stock of the Springfield (Mass.) Street Railway Company has been deposited with Lee, Higginson & Co., of Boston, who are financing the deal.

The Municipal Subway Company of New York has been incorporated at Albany with $100,000 capital to build conduits for electrical conductors. The directors are J. Bears, W. J. Boroughs and George Stewart of New York.

Both General Electric and Westinghouse interests admit that the best of feeling no longer exists between the managements of these two companies, which fact is sure to be reflected in rather severe competition.

The Public Service Corporation of New Jersey has increased its capital stock from $10,000,000 to $12,000,000 for the purpose of further developing the property of the company. The new stock will be issued to shareholders at par.

The control of the Hartford (Conn.) Street Railway Company was formally transferred Saturday to the Consolidated Railway Company, the holding corporation of the street railroad properties of the New York, New Haven & Hartford Railroad Company.

The People's Light, Heat & Power Company of Springfield, O., has been incorporated with a capital stock of $2,000,000. The deal is practically closed by which the new company will purchase the Springfield Light & Power Company, now owned by the American Railway Company of Philadelphia.

An alliance between the Metropolitan Street Railway Company of New York and the New York, New Haven & Hartford Railroad Company is now regarded as practically certain, if the Metropolitan system secures the franchise for the construction of new subways between the Bronx and the Battery.

EDITORIAL NOTES.

When Large Cities Will Have Cheap Electricity.

Agitation and legislation cannot effectively alter the actual cost of electricity. They may impose restrictions, through which a fancied relief is obtained, but the three great fuels of mankind, coal, oil and wood, will still be charged for at a rate which nets a reasonable margin of profit to their owners. The State recognizes the impossibility of imposing its will upon industrial enterprises whose business methods are clean in this respect. It cannot force concerns to sell coal or oil or wood at a loss, and therefore it is in many respects similarly situated with regard to those corporate interests self-intrusted with the great municipal responsibility of supplying electricity for lighting the city streets. These facts are known to be applicable, not only to specific instances where public sentiment has cried out against extortion, but to the great majority of cases where electricity performs this public service.

Therefore, the absolute cost of fuel and the cost of the complete electric light installation are, in the aggregate, the sources of expense—the one permanent the other continuous—upon which are based the charges for electricity. If the fuel charges are reduced to figures admittedly fair by the purchasers, and the installation of a central station and its many accessories is laid down on such economic lines as those best justified by the opinions of the most competent of engineers, then the outlay has not been excessive and it is necessary to consider the financial conditions involved, which must be the cause of such prices as are charged for electrical energy. These, in detail, cannot be adequately reviewed without special provision being made for many pages of statistics. Yet the general reasons may be briefly presented in conjunction with those that will indicate the time when large cities will have cheap electricity.

Among those that may be presented are such as refer to the earlier experimental period of electric lighting, that time during which the system required creation. Plants were constructed and reconstructed, and the entire lower section of New York was covered with an expensive underground network of wires. The earlier history involved heavy expenditures, which partly composes the debt of older companies in the lighting field. Much money had to be sunk before success came, in the shape of enough consumers of current to found the basis of an assured industry. The details, which in the end will constitute the complete elements of a great plant, are not as yet all perfect. Every half decade or decade sees changes of a most important nature. And it can be readily understood that with the swift advance of new devices in the field of electric lighting, the new additions will make as marked a transformation in the central stations of ten years hence as those of ten years ago have made in the present.

While it may be added that overcapitalization also adds its load of financial responsibility to the shoulders of those promoting the interests of electric lighting, frequently this is done in anticipation of a natural industrial growth and for this reason becomes absolutely legitimate. When this is carried on to excess, however, and the dividends that must be paid on watered stock constitute a burden to the community in the way of overcharges for current, it is quite evident that radical measures must be taken to modify such conditions and transfer the load to where it properly belongs.

Large cities will have cheap electricity if the great natural sources of power are employed whose utilization would result in low prices and efficient lighting and heating for even the most humble.

It would be very much better to burn coal at the mines and transmit electricity to New York at high pressure than ship coal here by steam roads for the same purpose. No well-constituted body of electrical engineers would refuse to entertain this idea seriously. On the other hand, water power in the Appalachian and Rocky Mountain ranges for the inland towns, and Niagara toward the north, would supply large amounts of power for industrial purposes. A system of tide motors highly developed has shown great efficiency at several points on the Atlantic and Pacific coasts in the last few years. It may not be too much like unwholesome anticipation to predict the erection of trunk power lines carrying the electrical energy for whole States in the near future. Such a public necessity like light deserves just as much consideration as pure water or fresh air. It will be only a question of time before this idea will burrow its way into the minds of the general public whose wish in this land is law.

* * *

Steam Engine Research.

For some years past a committee of the English Institution of Mechanical Engineers has been carrying out investigations upon the initial condensation in steam engine cylinders. The committee has now issued a lengthy report embodying particulars of what has been accomplished during the past six years.

The engine used for the research was a horizontal compound, with cylinders placed side by side, and of 6½ inch and 11¼ inch diameter and 14 inch stroke. Among the points elucidated were the following: First, leakage through the slide valve had been quantitatively determined under defined conditions, and shown to be nearly independent of speed of sliding surface, and proportional to difference of pressure between the two sides of the valve. Further, the assumption that the leakage was inversely as the overlap of the valve was shown to be at least in the main well founded; and it appeared that with well-fitted valves the leakage might amount to over 20 per cent. of the steam entering the cylinder, and was rarely less than 4 per cent. Second, it had been shown that for an unjacketed engine with a given ratio of expansion initial condensation, expressed as a percentage of the steam in the cylinder, diminished with increase of initial temperature, while the total condensation increased with such temperature increase. This had never before been demonstrated with clearness, since, if leakage were not allowed for, the results were obscured or even reversed. Third, it appeared that the re-evaporation for a given ratio of expansion was as great, and sometimes greater, without jackets as with them, this result showing that the regenerative action of the cylinder walls with a given ratio of expansion was largely independent of their mean temperature. Fourth, the results obtained indicated the temperature at which for any speed of revolution with a given expansion, jacketing would become unnecessary or wasteful.

If the heat units per indicated horse power per minute required by the unjacketed engine for each speed of the series were plotted either on an initial pressure or a mean effective pressure base, the points for each speed would be found to lie on four curves, which became closer and closer to each other as the speed increased and converged to a point as pressure or temperature increased. When the heat consumption for the jacketed series was likewise plotted, the points for the different speeds at each pressure lay irregularly round a point, their exact position being determined by the accidentally slight variations of the conditions of each trial.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

Several electric vehicles will be seen in the annual automobile parade in this city next Saturday. The parade will be under the auspices of the Automobile Club of America.

Prof. Wilhelm Ostwald, of the University of Leipsic, regarded as one of the founders of the modern science of physical chemistry, has been invited by Harvard University to serve as lecturer during the first half of the coming academic year.

Prof. A. S. Eve, of McGill University, Montreal, has discovered that the mere presence of radium in his laboratory prevented him from making a delicate electroscope. He found that all the materials in the building had been effected with radium activity. He got rid of some of the infection by washing the articles in hydrochloric acid, but enough was left to spoil the laboratory. The scientists at Columbia University, New York, have also discovered that their physical laboratories are being injured by radium. Not only have hundreds of thousands of dollars' worth of instruments in the laboratories here and elsewhere been "radiumized," but the gas given off from the radium prevents and will prevent for years to come the manufacture of any delicate electrical instruments in the laboratories. It is like spoiling a storeful of watches by bringing a magnet in their midst. A little piece of radium no bigger than a pea will put a whole laboratory out of business in no time and keep it out of business for two generations so far as electrical instruments of precision are concerned. It is claimed that new laboratories will have to be built especially for radium.

Prof. H. W. Spangler, of the University of Pennsylvania, will open a discussion on "Internal Combustion Engines" to-morrow (Thursday) evening at a meeting of the Franklin Institute, Philadelphia.

Prof. M. I. Pupin has been nominated for the award of the Cresson medal by the Franklin Institute for his "Art of Reducing the Attenuation of Electrical Waves and Apparatus."

The New York "Herald" printed the following in its Sunday issue: "It is understood that the agreement between the General Electric and the Westinghouse Electric & Manufacturing Companies regarding prices has been ended and that a reduction in prices of electrical equipment may be the immediate result. The two companies, during the last few years, observed an arrangement concerning certain kinds of electrical equipment whereby each secured its share in the business field agreed upon. Relations between the companies became strained during the last few months and the climax was reached when the Allis-Chalmers Company entered into the electrical field."

Prof. Charles P. Steinmetz will present two papers at the annual convention of the American Institute of Electrical Engineers, to be held at Asheville, N. C., June 19 to 23. The subjects will be "High Potential Oscillations of High Power in Large Power Distribution Systems," and "Theoretical and Experimental Investigations on the Disruptive Strength of Air at Very High Voltages."

The Chinese Government, according to an official report to the State Department at Washington, D. C., has granted its first patent. It is for an electric lamp, the inventor being an inhabitant of Nankin, the old capital of the Chinese Empire. The patentee calls his invention "bright moolight."

THE FRENCH FAYET-CHAMONIX MOUNTAIN ELECTRIC RAILWAY.

BY FRANK C. PERKINS.

A most interesting third-rail mountain railway was constructed by the Compagnie des Chemins de Fer de Paris-Lyon et a la Mediterranee between Cluses-Fayet and Chamonix in the Mont Blanc region of France. The first section of the line between Cluses and Fayet-St.-Gervais was not difficult to construct, but the second section between Fayet-St.-Gervais and Chamonix extended a distance of 19 kms. with a difference of level between the two stations of 458 meters while at certain parts the grades were exceptionally steep and many difficulties were encountered which required great engineering skill. The last section was electrically equipped with the third-rail system and followed along the valley of the Arve, crossing the same at several points, a number of bridges being required with spans varying from 25 to 45 meters. The viaduct of Sainte-Marie on this section has an arch of 25 meters span and 50 meters high with seven additional arches each having a span of 15 meters. One portion of this viaduct has a curvature of 200 meters radius. There are also three tunnels, one of which is 126 meters in length between Fayet and Chamonix the grades varying from 2 to 9 per cent., one grade of the latter amount extending a distance of 2,155 meters and another of 8 per cent. being 1,386 meters long There are four intermediate stations including Bossons, Houches, Servoz and Cheddes.

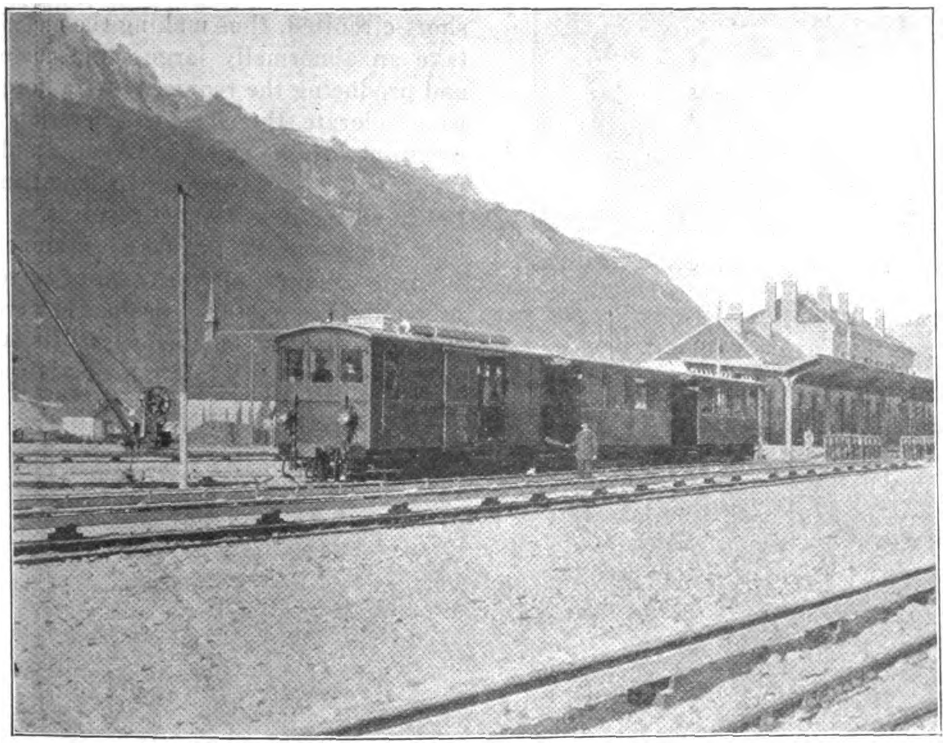

Fig. 1.—Motor Cars and Station of Mountain Electric Railway.

The current for driving the electric trains on this third-rail line is supplied from two generating stations, one located at Servoz, which supplies the first electric railway section, and another at Chevants, supplying the electric line extended towards the Swiss border and to Martigny. The Servoz station utilizes the water power from the river Arve, having an output of 12 cubic meters of water in summer and 6 cubic meters in winter, the effective head being about 40 meters. The Chevants power plant is supplied by a second branch of the Arve, the output being 11.5 cubic meters in summer and 5 to 6 cubic meters in winter with an effective fall of 94 meters. The current is supplied by four direct current electrical generators of 200 kw. each, directly connected to horizontal turbine shafts by flexible insulating couplings, the speed being 715 r. p.m. at no load and 450 r.p.m. at full load; the regulation is provided by compounding the generators. It is stated that the machines operate at no load at a speed o about 600 r.p.m. with a pressure at the terminals of about 550 volts, while with a load of 300 amperes, the speed dropping to 450 r.p.m., the pressure at the terminals is increased by over-compounding to take care of the loss in the feeders to over 650 volts. The Servoz station has a minimum output of over 2,000 hp. and a maximum output of 4,500 hp., the effective fall, as stated, being about 40 meters, and the water is utilized after leaving this plant by the he power station of the Cheddes Electro-chemical Works whose turbines operate under a head of 140 meters.

The Chavants power station was installed at a distance of about 10 km. from Fayet-St.-Gervais, the total capacity being 10,000 hp., the turbines having a normal flow of about 10 cubic meters under a head of 94 meters. A high tension alternating current is generated at a pressure of 10,000 volts for use on the transmission line, step-down transformers being utilized at various sub-stations along the line. The turbines and generators are of 1,200 hp. capacity, the current generated by these three-phase alternators having a frequency of 25 cycles per second. Rotary converters are installed at the sub-stations for supplying direct current to the mountain railway line and storage batteries are also provided for regulation.

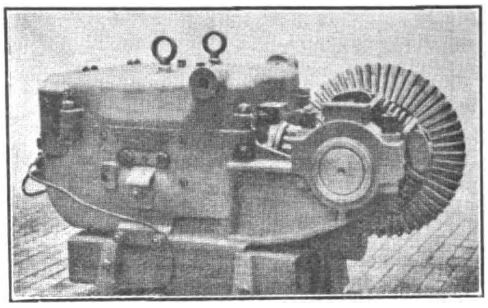

Fig. 2.—Electric Railway Motor and Reduction Gear.

The Fayet-Chamonix third-rail electric line has a gauge of 1 meter, the track consisting of Vignole rails 12 meters long and weighing 34.2 kg. per meter. The third-rail is used for supplying current to the electric motors on the trains and is of the same weight and section as the running rail, its upper surface being 23 cm. above the level of the track and located 1.083 meters away from the running track, in some cases on the right hand side and in others on the left. On this account two sliding contacts are provided on the cars so that current may be taken from either side of the track. In this way crossings and switches as well as changes of level do not cut off the current as one conducting shoe is always on a live rail. In order to prevent accidents from coming into contact with the live rail, which carries a current of 550 volts, it is protected by a wooden covering for a length of 10 meters on either side of the grade crossing. The third-rail is provided with brown plastic bonds and is insulated by paraffined wood supports. This mode of insulation is said to be very effective, the current leakage being less than 1 ampere per kilometer. It has been stated that the losses in winter from snow and from rain are very low, due to the fact that the water in the neighborhood of Chamonix is almost chemically pure on account of the purity of the atmosphere and is therefore a very poor conductor. It is stated that the rain washes off the dust from the insulating supports and there is even a less leakage than before.

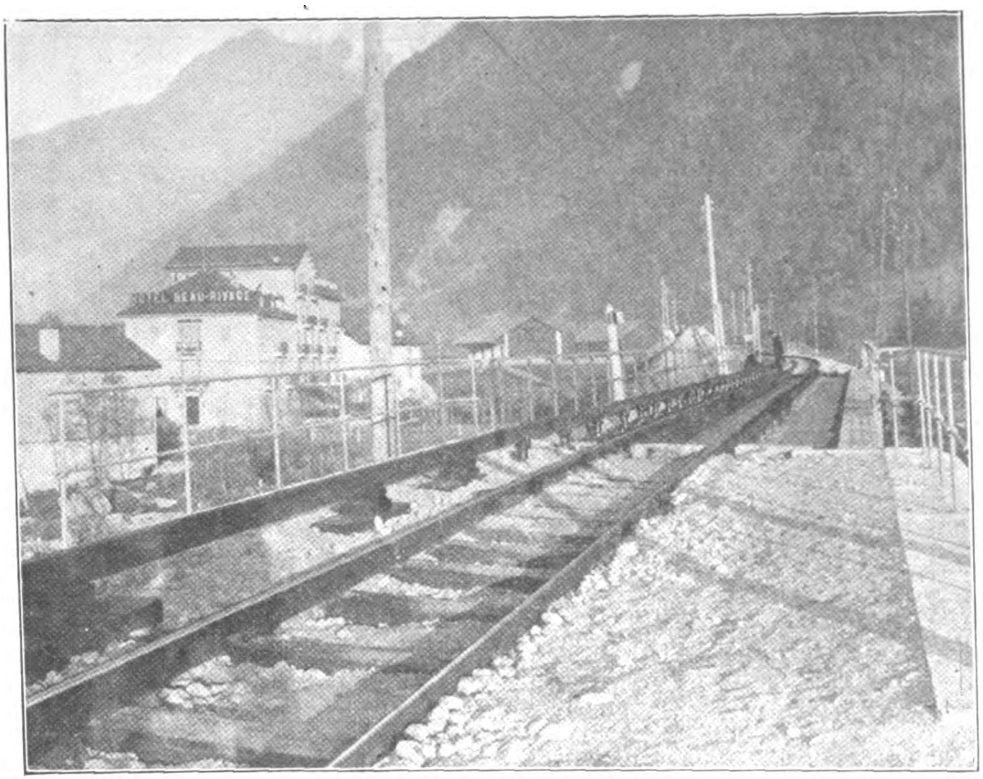

Fig. 3.—Track Construction and Third Rail of Mountain Electric Railway.

The cars and electric locomotives were constructed by the Societe Nouvellex des Etablissements de l'Horme et de la Buire of Lyons, France, while the electrical equipment of the same was supplied by the Society d'Electricite Alioth, of Munchenstein-Bale. There are on this line 80 motor cars as well as a number of trailers, the former weighing about 20 tons each and equipped with two 65 hp. electric motors each, the trains being operated on the multiple unit control system. There are ten passenger and freight trains operated on this line each way daily, a number of the motor cars on the passenger trains being provided with baggage compartments. The cars are provided with automatic and hand brakes as well as Christensen air brakes, an electrically operated compressor supplying the necessary air pressure. The trains operate at a speed of from 15 to 40 km. per hour, the latter speed being attained on the level portions of the line and the former speed when operating on heavy grades. The motors when operating at a speed of 275 r.p.m. take a maximum current of 200 amperes, when supplied with direct current of 550 volts pressure. The cars are lighted by a dozen 16 cp. incandescent lamps each and are also electrically heated.

Fig. 1 shows the motor car and one of the stations. Fig. 2 shows the motor inclosed and connected with its reduction gearing, which illustrates well the method of transmitting the power to the car axles on the Fayet-Chamonix line.

Fig. 3 shows the track construction and live rails at one of the stations while Fig. 4 shows a couple of electric railway motors used on these trains under test.

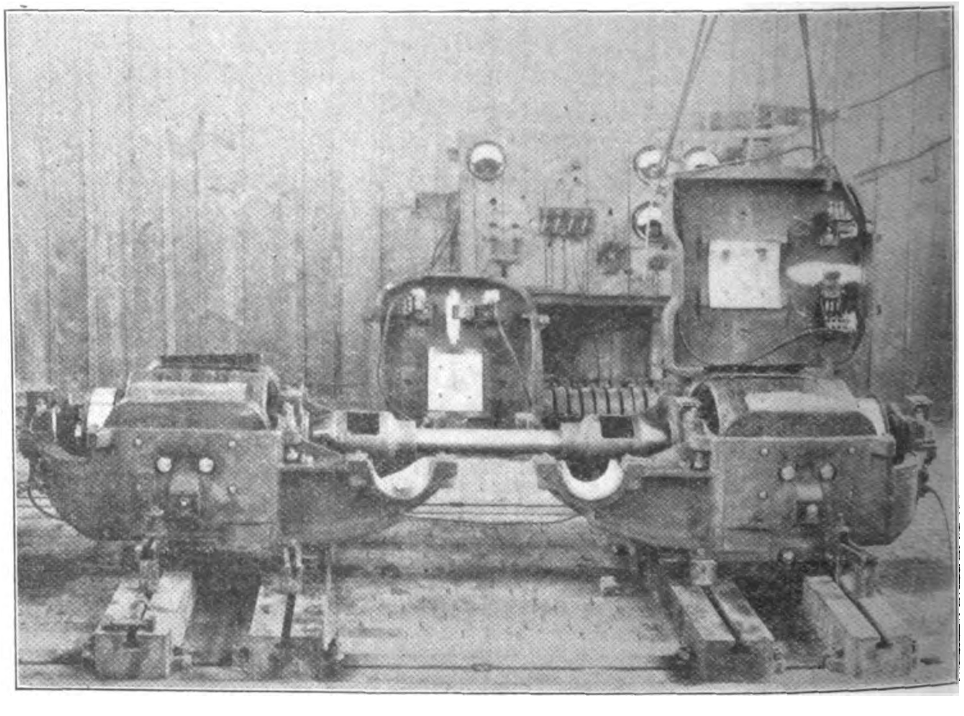

Fig. 4.—Test of Fayet-Chamonix Railway Motors.

* * *

A large amount of electrical business is coming to hand in New York from Central and South America, whose cities are now being equipped with electric street cars and electric lighting plants.

ELECTRICALLY-DRIVEN LIFTS.*

BY F. O. HUNT.

The question of the most suitable type of lift motor is a matter upon which considerable difference of opinion still exists. In some few cases series-wound motors have been used, but the practice can only be condemned as hopelessly bad. The choice lies, therefore, between shunt and compound winding. The reasons given by the advocates of shunt winding are mainly greater simplicity of only one magnet winding, less space taken by insulation, and greater simplicity of the controller. Where, however, shunt winding is used, it is usually designed as if for a lower voltage than that on which the machine is to be used, and a resistance is placed in series with it During the process of starting this resistance is short-circuited, thus making the machine take an abnormally large shunt current and producing the required extra torque to accelerate the load. Alteration of grouping of the shunt coils on a multipolar motor is also adopted by some firms, but in either case the net result is to obtain the required increase of ampere-turns by an addition to the shunt current taken by the motor. Seeing, however, that the greatest trouble with lifts supplied from public lighting mains is their tendency to cause fluctuation of voltage by their demand on the mains at the instant of starting, it is difficult to see how the shunt winding can be really as satisfactory as a properly designed compound-wound motor arranged to have its compound coils cut out after the process of accelerating is accomplished. The compounding merely takes the place of the last section of the starting resistance, so the complication of the controller is more imaginary than real. In this case the increase in ampere-turns is obtained by an alteration of the number of active turns, while the current value remains unchanged. In whichever way the increased excitation is obtained, it is essential that the magnetic density in the field magnet should be kept low so that the temporary increase in excitation shall be as effective as possible in augmenting the field strength, and consequently the starting torque. of the motor.

---

*Abstract of paper read before the Newcastle (Eng.) Local Section of the Institution of Electrical Engineers, March 20, 1905.

Where cheapness is an essential, hand-rope gear is at present the commonest method of operating the reversing and circuit-breaking switches. It usually consists of a more or less direct mechanical connection between what is virtually the handle of the switch and a rope. In many cases the reversing and circuit-breaking functions are both performed by the same switch, but there appears to be a tendency to separate the two operations. Probably this arises from the fact that with this arrangement it is possible to adopt more effective measures for magnetically blowing out the inevitable arc at the contacts. When speeds of more than 160 feet per minute are required it is now becoming usual to supersede the mechanical hand-rope transmission by an electrical method, in which the attendant merely moves a switch in the case. Where the cage-switch method is used the general practice is to avoid taking the actual power circuit to the cage, owing to the probabilities of trouble where heavy flexible cable is required. An independent circuit carrying a comparatively small current is led into the cage, this current being used to energize the operating solenoids of the power switches.

Formerly the American method of causing the motor to provide mechanically the motion necessary to cut out its own starting resistance was very much in favor and it is still retained by some makers owing to its inherent properties of preventing the motor being started against an overload, and also the certainty of a definite time being taken to cut out the starting resistance. It has, however, the serious drawback that, unless further auxiliary apparatus is employed, it is necessary that sufficient current to start the motor shall pass through it on the first contact stud. General practice now appears to tend in the direction of obtaining this motion electrically even when hand-rope control is in use. The time element during the process of acceleration is usually obtained by means of an air or oil dash-pot. To avoid the use of a dash-pot, some makers adopt an air-vane geared up to run at a very high speed. There appears, however, to be still room for improvement, as all methods of slowly-moving contact makers over studs are more destructive than intelligent hand working. What is wanted is a quick movement from one stud to the next and a prolonged pause on each stud, but an intermittent motion such as this is always difficult to obtain by mechanism that is at once cheap and reliable.

In the early days of electrically-driven lifts brakes were exclusively a mechanical matter and are so still in many cases where hand-rope control is adopted. When electrical control is used, it becomes necessary to lift off the mechanical brake magnetically, thus insuring that when current is "off" the break is "on," and vice versa. In the design of magnetically-lifted brakes there appears to be still room for improvement in the direction of arranging the link work so that the solenoid has a considerably greater mechanical advantage at the beginning of its travel than at the end, thus compensating for the inherent property of the solenoid that its pull is weakest where it is desirable that the greatest force should be available.

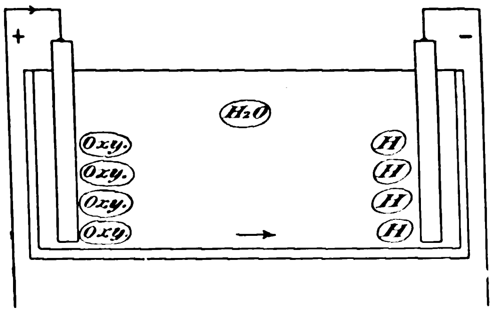
The supplementing or replacement of the mechanical brake by a retarding device depending on electromagnetic action, due to the motor being used as a dynamo, is a development which is growing in favor and undoubtedly further changes in the same direction may be expected in the near future. The facts that such a device can be made much more even in its action and is capable of much finer adjustment than any brake depending on an erratic coefficient of solid friction are strong points in its favor. Where only mechanical braking has been used, the writer has seen the end of the motor shaft twisted off by the action of the momentum of the armature combined with an excessively severe application of the brake. This latter circumstance is always liable to occur owing to the anxiety of the maker of the hoisting gear to reduce the error in stopping at floors to a minimum. The ideal brake evidently should be such that the armature will be caused to dissipate the whole of its own kinetic energy in the same time that the mechanical brake is performing a similar office for the mechanical parts of the system, thus relieving the motor shaft from all twisting stresses no matter how quickly the stopping may be done. Where push-button systems are in use the range of error in the stopping point becomes rather an important matter. Some makers provide two additional buttons in the cage to enable the user to adjust its position with regard to the floor. What really is required in such a case is a method of varying the braking effect according to the load in the cage.

ELECTRICITY LEAFLETS.

BY NEWTON HARRISON, E. E.

ELECTROPLATING.

Theory of Electrolysis.—That which is called electrolysis is a department of electricity which treats of the effect of a current upon a so-called chemical compound. By this is meant, that water, for instance, will succumb to the influence of electricity and become the two gases, oxygen and hydrogen, its actual constituents. And the same is true of other forms of matter as well. The action of a current is said to decompose the original body, and overcome in part or wholly the chemical affinity which exists between the elements of which it is composed. It is impossible to pay the proper attention to the effect of a current upon a solution within which are placed electrodes, unless the modern aspect of this branch of practical science is correctly presented. To accomplish this, it must be stated that the chemical theory has been supplanted by the electro-chemical theory, and this theory is based upon the idea that all elementary forms of matter possess charges of electricity. Some such a conclusion was necessary on account of the quality of valency possessed by atoms and molecules. By this is meant the peculiar choosing power, of oxygen for instance, for two atoms of hydrogen or of hydrogen for chlorine, etc. In other words, the elements when in the form of atoms have strange likes and dislikes which manifest themselves in the form of certain affinities for each other. Through these fixed affinities, the elements, as they are called, form chemical combinations, as in the case of water or acids or any other familiar or unfamiliar form of matter. This choosing power inherent in the atoms, given by chemists the name of valency, is attributed to varying charges of electricity by the electro-chemist. Thus the combination of oxygen and hydrogen is due to the electrical attraction of oxygen for hydrogen. On this basis, either one or the other must have a positive or negative charge. This charge, if powerful enough to form so intimate a combination, must be highly concentrated, because of the exceedingly small dimensions of the atoms and molecules themselves. In the case of water, it is a well-known fact that a current of electricity will decompose it into oxygen and hydrogen; and the curious phenomenon presenting itself under these circumstances will be that of the oxygen always clinging to the positive pole of the battery and the hydrogen to the negative. Placing two copper plates in a slightly acidulated solution, connected to a source of electricity, will demonstrate this principle. The great mass of bubbles at the negative pole will serve to prove that twice as much hydrogen as oxygen is evolved. The combination forming water being two of hydrogen to one of oxygen, the gases collected will be in harmony with this proportion. As far as the practical application of this principle is concerned, the amount of gas evolved by this process can be calculated with mathematical certainty. Not only is this true, but if the two poles of a battery, which when employed for electrolytic work are called electrodes, are used in connection with a metal salt solution such as water and sulphate of copper, a coating of copper will be deposited upon the negative electrode, which as well, can be estimated beforehand with the greatest accuracy. The estimates made in the case of the gas refer to the quantity of it which will be evolved per unit of time. In the case of the copper the same holds true. In both cases the fact is clearly presented that certain conditions must be considered as follows:



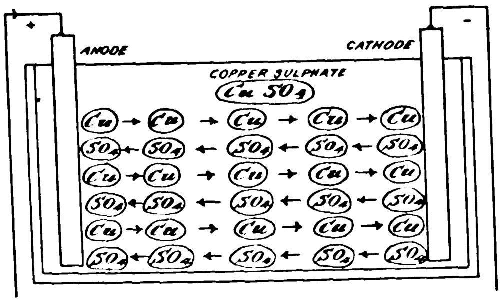
The division of the water molecule into oxygen and hydrogen.

First—The strength of the current in amperes.

Second—The time in seconds during which the current flows.

These considerations lead to an examination of the hypothesis which is supposed to explain that which is called electrolytic action. The two battery terminals, called electrodes, are also named with reference to further distinctions. The positive pole is called the *anode*, the negative pole the *cathode*.

The Grotthus Hypothesis.—According to this hypothesis framed by Grotthus, when metals are being deposited, a curious transference of metal is taking place within the solution. Take, for instance, the case of copper being deposited from a solution of sulphate of copper. The chemical aggregations composing the copper sulphate are as follows:



The migration of the anions and cathions under the directive influence of the current.

Copper sulphate = $Cu\,SO_4$.

This is divided up into two groups of atoms, one of which is positive and the other negative. The sub-divisions are those of the copper, and the oxygen and sulphur as follows:

Copper = Cu moves toward the cathode.

Oxygen and sulphur = SO_4, moves toward the anode.

According to this idea the electrolytic bath with the two electrodes immersed is traversed by two streams of atoms, one going to one pole, and the other to the other pole. But according to the Grotthus hypothesis, the solution of copper sulphate and the two streams of traveling atoms act in a very interesting manner toward each other. The solution of copper sulphate, for instance, permits a copper atom to leave the copper anode from which it has been electrically removed; seizes it, but sends on its own atom of copper in place of the first to its destination, the cathode. The same process is carried out with respect to the oxygen-sulphur molecule. Thus the solution acts as an intermediary, whose strength will remain unaffected as long as the anode replenishes the lost atoms.

An exchange goes on continually, with the result that the copper anode will gradually become lighter and its metallic equivalent will be found at the cathode or on the objects placed there to receive it. These two oppositely moving streams of electrified particles have been designated streams of ions, from the idea that these infinitesimal forms of electrified matter are, as the word expresses it, travelers.

If the anode is of a neutral metal, for instance, or of carbon, then the solution used in this experiment, will systematically weaken.

The Electro-Chemical Equivalent.—The carriers of electricity being these ions, it follows as a logical consequence of this hypothesis, that these ions may or may not carry equal quantities of electricity in the electrolytic experiment. To satisfactorily settle this question, a series of baths of silver solution, copper solution, etc., were prepared with electrodes of the proper character. The current sent into each was carefully measured, and the time during which this current flowed correctly gauged. It was found that in each case different results were obtained, although the current was preserved at a uniform value. The amount of metal deposited, of silver or copper as the case presented showed, were different in each case. In other words, a broad principle was discovered underlying these experiments, a principle which showed that each particular metal was unique in this respect, that its ions or charged atoms were each the carriers of only a specified amount of electricity which was different with every different form of matter tested. The metals particularly, displayed such differences that a table was drawn up, called the table of electrochemical equivalents, under whose heading was given the exact weight of metal carried over by one ampere in a second. This, in fact, is the definition of the electro-chemical equivalent of a metal; the weight of the metal in grams carried over by a coulomb of electricity, that is, an ampere second. On this basis, the weight of any metal, such as gold, silver, copper, lead, etc., carried over by a certain current in a certain time, can be readily ascertained by a simple calculation.

How to Calculate the Weight of Metal Deposited.—In practical electroplating the judgment and experience of the plater is employed to its fullest extent in the determination of the amount of metal deposited on an object being plated. The weight of metal can be calculated from a knowledge of the time in seconds and the strength of the current in amperes as follows:

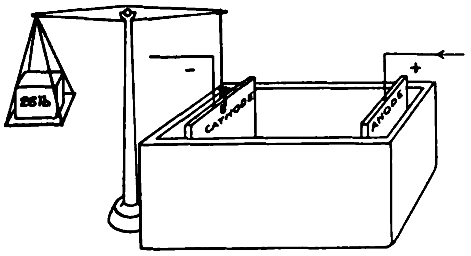
Weight in grams = weight per second per ampere × current in amperes × time in seconds. Reducing to symbols, the formula reads:

$$W = T \times E.C.E. \times C.$$

Where W = weight of metal deposited in grams.

T = time in seconds.

E.C.E = the electro-chemical equivalent (that is, the weight of metal due to one ampere in one second or one coulomb). To illustrate this idea suppose a current of 100 amperes is employed for copper plating for 100 hours, then as the electro-chemical equivalent of copper is .0003281 the total weight of copper plated over would be



Electrolytic deposit of 26 pounds of copper in 100 hours with 100 amperes.

Grams = 3600 × 100 × .0003281 × 100.
Grams = 11811.6.
Total weight = 11.8 kilograms.
Total weight = 26 pounds of copper.

This is the influence causing discrimination between the ions for either anode or cathode in electrolysis. When copper plating is done the Cu and SO_4, or copper and so-called sulphion, divide, the copper depositing on the cathode and the sulphion forming sulphuric acid by combining with hydrogen giving H_2SO_4 and thus intensifying the acidulation of the solution.

Table of Electro-Chemical Equivalents.—To calculate the weights of metal or gas carried over to the cathode by electrolytic action a reference table is supplied giving the name of the element, its atomic weight, its valency, its chemical equivalent and its electro-chemical equivalent:

TABLE OF ELECTRO-CHEMICAL EQUIVALENTS.

Elements.	Atomic weight.	Valency.	Chemical equivalent.	Electro-chemical equivalent in grams per ampere second.
*ELECTROPOSITIVE.				
Hydrogen	1	1	1	0.000010384

Nitrogen	14.01	3	4.67	0.00004849

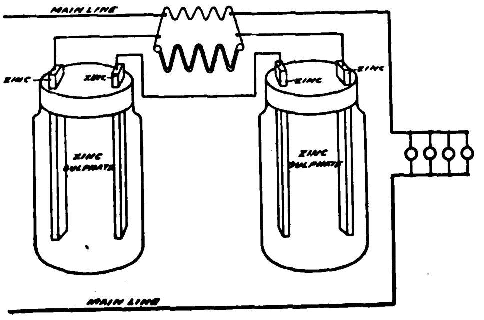
*Table from S. P. Thompson's "Electricity and Magnetism."

In the above calculation the 3600 is the number of seconds in one hour, then follows the E.C.E. and the 100 amperes.

Anions and Cathions.—The atoms carried forward to the negative plate or cathode are called cathions and those passing the anode are called anions. The metals all move toward the cathode and are therefore termed cathions, also the gas hydrogen, which thus betrays the properties of a metal in an electrical sense. The anions are oxygen, chlorine or other elements moving toward the anode. This peculiar qualification has led to the conclusion that the natural charge possessed by atoms determines their position in the electrolytic bath as anions or cathions. The so-called anions or ions with an attraction for the positive electrode are regarded as negatively charged and are called "electronegative." The cathions the reverse or positively charged.

The idea of employing an electrolytic meter to determine the amount of current consumed by customers from the increased weight of the electrode is based entirely upon the electro-chemical equivalent.

The original Edison Illuminating Company of New York used thousands of zinc sulphate meters, composed of two electrodes of zinc in a zinc sulphate solution and receiving a shunted current from the customer's mains. Each month the meters were replaced by new ones and the added weight of the cathodes of the old ones carefully ascertained. The number of ampere hours were thus determined on the basis of the electro-chemical equivalent.



Equipment of Edison meters of the Electrolytic type. Low voltage obtained from drop in shunt.

The final estimates were based upon the number of milligrams of zinc deposited, each of these costing a certain amount, the total weight giving the bill for current.

CONVERSION OF A TELEPHONE EXCHANGE FROM THE MAGNETO TO THE CENTRAL BATTERY SYSTEM.*

BY B. S. COHEN.

When an existing telephone system has to be converted from one method of working to another, a considerable number of important points immediately present themselves for consideration, the point of chief importance being the necessity for carrying out the conversion with the minimum of inconvenience to the telephone public.

It may be interesting to many to outline the methods which have been adopted for carrying out such a conversion.

The methods to be described have been employed in the main in connection with a considerable number of large exchanges in this country.

The requirements of the new exchange as regards commencing equipment and ultimate capacity are the first consideration, and to this end the department dealing with the traffic furnishes complete records of the normal daily exchange load for the various kinds of local and junction services, and also particulars of the past rate of increase and estimated future increase in the various types of services.

From these particulars the number of lines which an operator can deal with and the number of operators' positions required are determined. In the conversion of a large area with a considerable number of exchanges, the design is complicated by the necessity for allowing for a lighter operator's load during the transition period when the exchanges in the area are working partly on the old magneto and partly on the new central battery system, and the junction work is consequently more difficult than when the conversion of the whole system is completed.

The operators' load is settled on the

---

*From the "Electrical Review," London.

basis of calls per busiest hour, and it is interesting to note that there is a constant ratio between this figure and the total calls per day which varies very slightly, if at all, in any one exchange.

This ratio, however, varies for different types of exchanges, and is largest in exchanges where a considerable proportion of the area served is residential, as in such cases the calls are spread well over the whole day, the morning and afternoon maxima and the lunch and early and late minima on the load curve not being so steep as in the case of an exchange in a business area.

The ratio of local calls to calls for other exchanges is another important particular which must be supplied by the traffic department. As illustrating the importance of this point, it may be mentioned that in many exchanges the local calls form such a small percentage of the calls for other exchanges that the subscribers' multiple used for the former gets very little work and in such cases it is quite feasible to economize in the number of multiple spring jacks by spreading out the multiple. For example, in a 12,000-line exchange, by making the subscribers' multiple repeat every 9 panels, or 6 feet 4½ inches, instead of every 8 panels, or 5 feet 8 inches, a saving of about 67,500 multiple jacks is effected, costing with labor of wiring, etc., about £2,250, and it must be borne in mind that this is effected without detracting from the commercial efficiency of the switchboard. It follows from this that if the proportion of local calls became very small, it would pay in practice to do away altogether with the subscribers' multiple. As the junction multiple on the incoming junction boards is used for every connection, the foregoing does not apply, and indeed it is customary to reduce the number of panels per complete multiple on such boards.

Fig. 1.—Conversion of a Telephone Exchange.

The size and general design of the exchange having been settled, the selection of suitable premises is the next consideration. The situation of the exchange with respect to the subscribers depends to a great extent on the variation in the density of the subscribers in the different localities served, and is complicated to a certain extent by wayleave considerations and the physical nature of the area.

Assuming that the old exchange is in the most suitable position for serving its subscribers, the new premises would be obtained as close as possible to the existing one.

It very rarely happens that the latter can be utilized for the new exchange, and whenever possible new premises are built specially designed for the work. It is advisable to put the apparatus and accumulator rooms as near as possible to the switchroom, in order that the cables between the two should be of a minimum length. On the other hand, the operators' dining rooms, etc., should also be in close proximity to the switchroom. In practice a satisfactory arrangement for exchange premises which is often met with would have the apparatus and accumulator rooms on one floor, the former containing the main and intermediate distributing frames, power apparatus, etc. The operators' dining, recreation and cloak rooms would be on the next floor above, and the switchroom on the top floor, to allow of roof lighting.

The ideal shape of such a building should be rectangular with a minimum width, such that a whole number of switchboard sections can be turned in the switchroom, thus avoiding the use of dummies at the bends. This is an important point, as in an exchange known to the writer the bad shape of the building has necessitated a considerable number of dummies, the capital locked up in which represents an annual revenue of several hundreds of pounds.

Fig. 2.—Norwich Exchange, Apparatus Room.

A plan of "North" switchroom, a new exchange of the National Telephone Company serving a portion of the north of London, is illustrated in Fig. 1. It will be seen that the subscribers' sections sweep round one side of the room and the incoming junction boards round the opposite side, both runs of boards starting from the same corner. The capacity of this switchroom is quite small, being only about 4,200 subscribers and 486 incoming junctions, but it has been selected as an example approaching the ideal arrangement. It may be of interest to mention that this exchange is built in an old chapel, at one time the property of the Sandemanians, at which it was stated Faraday himself was wont to attend.

A typical method of arranging the apparatus room is illustrated in Fig. 2. This shows the method adopted at the Norwich exchange. The outside lines terminate on the main frame, which also carries the lightning and stray current arresters. This frame is generally arranged to give a capacity for outside cable leads of at least 25 per cent. more than the ultimate capacity of the exchange, in order to allow for non-utilized wires in cables. This frame can be extended when necessary. The main frame has displaced the old-fashioned test board as with the central battery system the nature of practically all faults can be determined from the multiple.

The intermediate frame cannot be conveniently extended and is installed with the ultimate capacity. A detailed description of the foregoing and other apparatus shown in the plan in Fig. 2 is beyond the scope of this article. The racks which carry the cables between the various pieces of apparatus are made of strap and angle-iron and are carried overhead.

As a very large number of cables are required, all of which must be brought out in a certain consecutive order at both ends, the design of the racks and the arrangement of the cables demand careful forethought. An example of cable work is shown in Fig. 3. This is the rack carrying the multiple cables from the intermediate distributing frame at Holborn Exchange.

The arrangement of the power apparatus is shown in Fig. 2. The motor-dynamos for charging the battery are in duplicate as are also the machines for providing 15-cycle alternating current for ringing purposes. If possible, there should be two distinct sources of power for driving the charging machines, and the ringing motor-generators are driven generally one from the main supply and the other from the battery.

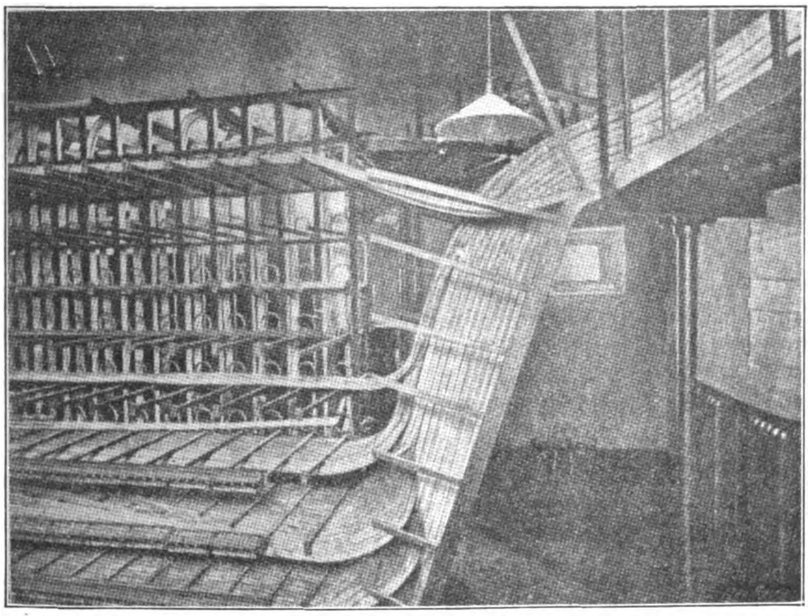

Fig. 3.—Holborn Exchange, I. D. Frame and Cable Rack.

The accumulator room contains the main 11-cell battery and the smaller 4 cell battery, which acts as a booster for the service registers—i. e., call-recording meters. The main battery should be provided with sufficient plates to hold a two day's load for the first three or four years' life of the exchange, and the tanks with room enough to take plates for the ultimate capacity of the exchange.

The power apparatus is generally so designed that one of the charging machines, running for two or three hours in the morning and afternoon at the peaks of the day load, keeps the cells full, besides which they are given a weekly "milking" to keep them in good condition.

(*To be continued.*)

A public conference will be held in Chicago at an early date between the traction interests, the committee on local transportation and the Mayor of that city, with a view to ascertaining a basis for the purchase of all of Chicago's traction lines.

A NEW USE FOR ELECTRICITY.

(From the New York Times.)

In conversation yesterday, a practical electrician who at one time acted as selling agent for a firm manufacturing electrical supplies, including incandescent lamps, disclosed "a trick of the trade" which, though it has some slightly dubious aspects, is certainly interesting and, to us at least, entirely novel. What he said was that while "on the road" in winter he was often obliged to pass the nights in hotels where, though most of the "modern improvements" were present, the bedrooms were usually very cold and the sheets often very damp. When it was a hotel that had electric lights he materially mitigated these woes by extracting from his "grip" a 32 candle lamp, equipped with insulated wires long enough to run from the bed to the nearest fixture, and ending in a "plug" that would take the place of a lamp destined for illuminating purposes. When ready for retirement he would remove the lamp, usually a small one, attach his own big one, and, with the latter for companion, seek the seclusion of the icy sheets. They never remained icy long, he declared, for a 32-candle lamp gives out a considerable amount of heat, mild and continuous. In the circumstances, this would obviously be a simple and efficient expedient, although we have more than a suspicion that the hotel keepers would not regard it with approval and we have more than half a suspicion that practice of the plan would be attended with some danger of accidents of several kinds. Shoved well down towards the foot of the bed, the light of the lamp would be no annoyance, while it would make no trouble as long as the insulation remained perfect and no unguarded movement with a bony heel shattered the fragile globe. That once broken, however, there would be an explosion that would at least give a somewhat painful start to the lamp's bedfellow and other mishaps might follow, possibly to the imperiling of the whole house. That is a question for the experts to decide, and as the expert who made the revelation was not afraid to try the experiment, presumably the peril is not excessive. At any rate the idea is a queer one, and the opportunities for exploiting it, if it is of any value, are not confined to hotels in the hinterland.

ANCHORING POLE LINES.

It is absolutely essential that every pole line should be properly guyed. To accomplish this very many street railway, telephone and electric light companies are making use of what is known as the Stombaugh guy anchors, manufactured by W. N. Matthews & Bro., 219 North Second street, St. Louis, Mo.

Some idea of the holding power of these anchors may be had from interesting tests made by Prof. R. C. Carpenter of Sibley College, Cornell University. Referring to the matter, he says:

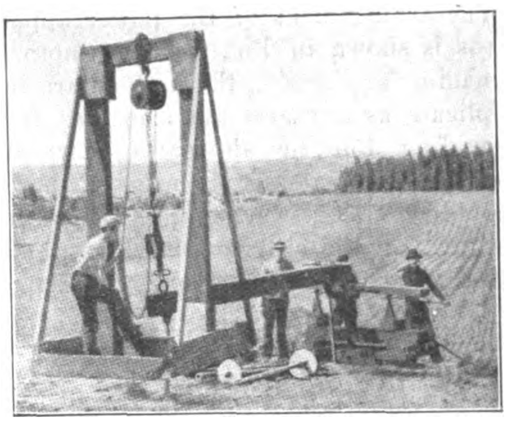
"Nearly all the important pole lines need lateral support, which is best given the poles by attaching guy wires to some suitable anchorage. Various forms of anchors have been used, varying from bars of iron driven in the ground, flat plates buried some distance, pieces of trees, cross-ties as 'dead-men,' and parts of poles as stubs, to complicated and expensive forms. In many cases the lateral pull on poles, due to the weight of the wires, wind stresses, etc., is of such an amount that unless the pole was thoroughly guyed laterally to some anchor, it would not maintain its position.

"During the past few months, the writer had an opportunity of investigating the holding power of a simple anchor, the results of which are believed to be of considerable general interest, as this anchor can be placed in the ground without any digging and will hold an enormous strain.

"The anchors to which I refer are termed after the inventor, the 'Stombaugh Guy Anchor.' They are made of various sizes and consist in each case of one full helix or screw thread of cast-iron, which is attached either to a long iron bar or to a guy wire, as desired. In general, the anchors are quickly and readily inserted in the ground.

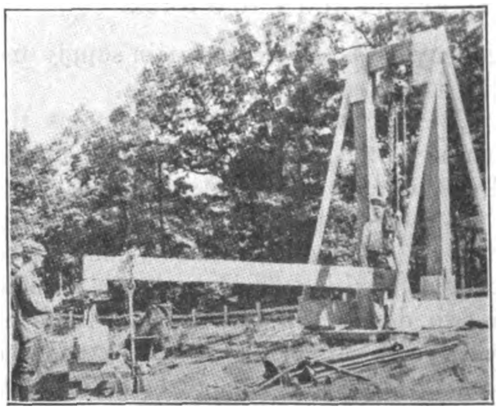
"Before making the tests, the writer considerably underrated the holding power of these anchors and was much astonished to find the magnitude of the resistance which they offered.

"The anchors were inserted in both sandy and clay soil, a suitable location being selected near the University. For the purpose of drawing the anchors from the ground, a dynamometer was arranged, which consisted substantially of a long wooden lever, one end of which was supported on rolling knife edges by a cross bar, which could be raised or lowered by jack screws; the other end was connected to a recording dynamometer, which could be raised or lowered by chain blocks. The anchor was attached to a rolling knife edge by a chain yoke connected to the eye of the anchor, so as to give a mechanical advantage of eight to one to the arm of the lever connected to the registering dynamometer. The reading of the dynamometer, multiplied by a constant factor, gave the holding power of the anchor. During the operation of testing, the long horizontal lever was kept level by raising both ends at the same rate. The arrangement for testing, as described, is very clearly shown in the accompanying illustrations.



SHOWING TEST IN SAND.

"During the tests, a slight movement of the anchor was always obtained before the maximum resistance was reached. After a movement which varied from ½ inch to 2 inches, the resistance fell off very rapidly. The holding power in clay was essentially greater than that in sand when the average of all cases are considered, the resistance being from 15 to 20 per cent. greater, but the range of testing could not, on account of conditions, be extended so far.



SHOWING TEST IN CLAY.

"The anchors were in every case pulled up very shortly after being inserted in the ground, so that it is extremely probable that the results of the tests are considerably less than would be experienced in practical use after the ground had settled.

"By comparison of the various results, it was found that the resistance of the anchors in sandy ground can be expressed very closely by the formula:

$$R = 100\,D\,H^2$$

in which R is the resistance offered by the anchor, in pounds; D is the diameter of the helix of the anchor, in inches; H is the depth of the helix, in feet, from the surface. The resistance for clay ground would probably be 20 per cent. more.

"As an example: A 10-inch anchor should have a holding power, in sandy ground, when 3 feet deep, of 100 × 10 × 9 = 9,000 pounds. This was less than was found with an anchor of this size. In a similar way, the 12-inch anchor, 4 feet in the ground, should have a holding power equal to 100 × 12 × 16 = 19,200 pounds. In an actual test, the anchor in this condition resisted 18,400 pounds. This was about the only case found when the holding power of the anchor was less than would be given by the formula. For these reasons, the formula is believed to be a safe one, especially when it is considered that the resisting power of the anchors will be increased after they have remained sufficiently long for the ground to consolidate.

"Taking all in all, the test gave some valuable data as to the holding of ground anchors, and indicated that great resistance can be secured by the use of simple helix form of anchors."

Municipal Electricians' Convention.

The tenth annual convention of the International Association of Municipal Electricians will be held in Erie, Pa., August 29, 30 and 31. At this meeting will be presented the following papers:

"Electrical Induction, Its Effects and the Application of Methods Used to Counteract It."

"Advisability or Inadvisability of Fusing Fire and Police Telegraph Boxes."

"Suggested Improvements in Fire Alarm Telegraphs."

"Underground Construction."

"The Necessity of a Rigid Inspection by the Municipality."

"Electric Light Engineering."

"Electric Light Plants."

These papers have been assigned to men who are thoroughly conversant with the subjects selected.

* * *

Dynamo Tender Wanted.

The United States Civil Service Commission announces an examination at San Francisco, Los Angeles, Fresno and Marysville, Cal., and Reno, Nev., on May 3, for dynamo tender. There is a vacancy at this time in the quartermaster's department at large, Presidio of

San Francisco, at $780 per annum. Age limit, 20 years or over on the date of examination. Apply to the United States Civil Service Commission, Washington, D. C., for application form 1,093, which should be properly executed and filed with the Commission at Washington.

Shell Type Transformers for High Voltages.

Editor Electricity.

Sir: We note in Mr. A. Frederick Collins' article on "High Potential Apparatus for Wireless Telegraphy," in your issue of April 12, he makes the statement that the transformer usually employed for wireless telegraphy is known as the core type. This broad statement is apt to be very misleading, inasmuch as the shell type transformers have been wound for 20,000 volts and very successfully used by the Government and leading wireless telegraph companies for some time, so that experience has shown that carefully designed shell type transformers can be built for high voltages fully as well as any core type transformers. Yours truly,

Edward A. Wagner.

Fort Wayne, Ind., April 19, 1905.

"American Exporter's" Compliments.

Electricity Newspaper Company:

Gentlemen: Please change the address of the "American Exporter" from Bennett Building to 120 Liberty street, New York City.

Let me take this opportunity to compliment you on the appearance and high grade of Electricity. Our editorial department would regard it as a misfortune to miss a single issue.

Very truly yours,

Edgar Allen Forbes,
Managing Editor.

Proposals Invited.

Sealed proposals are being invited until May 3 for furnishing and installing interior and exterior electric wiring and fixtures, and supplying current at Fort Brady, Mich., for one year, with privilege of renewal. Information will be furnished on application to Lieut. C. S. Hoffman, Fort Brady, Mich.

The Bureau of Supplies and Accounts of the Navy Department is inviting sealed proposals until May 9 for furnishing the Boston, New York and other Eastern Navy Yards with the following: Schedule 197, generating sets, magnet wire, slate slabs, conduit fittings, thermostat springs, etc.; schedule 198, motors, etc., batteries. Blank proposals will be furnished on application to the Navy pay office in New York or to the Bureau. Applicants should designate by number the schedules desired.

SOCIETY NEWS.

New York Electrical Society.

The 250th meeting of the New York Electrical Society will be held at 19 West 44th street, Wednesday, April 26, at 8 P.M. Mr. N. J. Neall will lecture on "Lightning Protection for High-Voltage Circuits." The lecture will be a resume of the development of lightning protection apparatus in America and abroad. A description will be given of the problems, their scientific character and bearing on the important question of lightning protection for high-voltage circuits, with a presentation of the favorable way in which these problems may be solved.

American Institute of Electrical Engineers.

The New York meeting of the Institute will be held at 154 West 57th street on Friday, April 28. Instruments and measurements will be discussed, the announced papers being as follows: "Polyphase Metering," by Prof. J. D. Nies of Lewis Institute, Chicago; "Notes on the Use of Instruments on Switchboards," by F. P. Cox of the General Electric Company, Lynn, Mass.; "The Oscillograph and its Uses," by Louis T. Robinson of the General Electric Company, Schenectady, N. Y., and "Maintenance of Meters," by W. J. Mowbray of the Brooklyn Edison Company.

PERSONAL MENTION.

Mr. John M. Mack has resigned as president of the Keystone Telephone Company of Philadelphia and Jacob E. Ridgeway has been chosen his successor.

Mr. Wilbur B. Driver, of Newark, N. J., has disposed of his interest in the Driver-Harris Wire Company and resigned as president of that company.

The Allis-Chalmers Company to Remove its Offices.

After May 1, 1905, the general offices of the Allis-Chalmers Company will be removed from the New York Life Building, Chicago, and will be located at Reliance Works, Milwaukee, Wis., which will hereafter be the headquarters of the vice-president and general manager, comptroller, assistant treasurer, office counsel, accounting and credit departments and also managers of power, pumping engine, mining and crushing machinery, flour mill and saw mill departments. The Chicago district sales office of the company, including that of the electrical department (the Bullock Electric Manufacturing Company) will also be removed from the New York Life Building and will be located in the First National Bank Building, Chicago.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED APRIL 18, 1905.

Electric Railways and Appliances.

787,527. Trolley-Retriever. Francis M. Miller, Arcadia, Ind. Filed Feb 2, 1905.

787,595. Electric Train-Signal. Albert W. Sullivan and William Renshaw, Chicago, Ill. Filed Aug. 5, 1904.

787,684. Trolley. Louis Leuenberger, Van Ness, N. Y. Filed Jan. 28, 1905.

787 810. Trolley-Pole Catcher. John H. Walker, Lexington, Ky. Filed June 6, 1904.

787,827. Electrically-Controlled Railway-Switch. Robert V. Cheatham, Louisville, Ky., assignor to the Cheatham Electric Switching Device Company, same place. Filed Aug. 9 1904.

787,856 Switch for Suspended Electric Railways Rudolf Pfaffenbach, Leipsic, and Hermann Muller, Leipsic-Gohlis, Germany. Original application filed Jan. 13, 1904. Divided and this application filed Oct. 29, 1904.

Electric Lights and Appliances.

787,428. Incandescent Electric Lamp. Frank H. Blackburn, Fostoria, O., assignor to the National Electric Lamp Company, Cleveland, O. Filed Jan. 6, 1904.

Electrical Machinery and Apparatus.

787,653. Electrical Stop-Motion Mechanism for Textile Machinery. Joseph B. Whitney, New York City. Filed June 30, 1903.

787,722. Motor Controlling and Regulating Device. Otto C. Britsch, New York City, assignor to David Wald, same place. Filed Aug. 31, 1903.

787,738. Motor-Starting Device. Arthur C. Eastwood, Cleveland, O. Filed Sept. 9, 1904.

787,820. Insulation for Electric Conductors. Lawrence E. Barringer, Schenectady N. Y., assignor to the General Electric Company. Filed Jan. 30, 1905.

Telephones and Telephone Apparatus.

787,361. Telephone-Transmitter. John Erickson, Chicago, Ill., assignor to the Strowger Automatic Telephone Exchange. Filed May 4, 1903. Renewed Oct. 3, 1904.

787,386. Support for Telephone-Receivers. Eldridge H. Little, Oskaloosa Ia. Filed Aug. 24, 1904.

787,507. Automatic Annunciator-Restorer. James I. Gemmill, Cleveland, O., assignor to the Gemmill Telephone & Manufacturing Company, Orrville, O. Filed Dec. 22, 1902.

787,583. Telephone Receiver. Charles T. Mason Sumter, S. C., assignor to the Sumter Telephone Manufacturing Company. Filed Feb. 27, 1905.

787,610. Telephone-Transmitter. Henry P. Clausen, Chicago, Ill., assignor to the American Electric Telephone Company. Filed Aug. 19, 1901.

787,879. Telephone Call or Ringer. Charles E. Egan Durham, N. C. Filed Aug. 13 1902.

Miscellaneous.

787,371. Lightning-Arrester. Lara M. Gates, Charlton, Ia. Filed Aug. 16, 1904.

THE TELEPHONE WORLD.

Receiver for Telephone Company.

News from Trenton, N. J., states that Edwin Robert Walker, of that city, has been appointed receiver for the State Telephone Company by Vice-Chancellor Bergen. The application was made by J. Pratt Cramer. The company has a line running from Trenton to Bound Brook, and one from Bound Brook to Jersey City, consisting of wires and poles on the Lehigh Valley Railroad Company's right of way. The company has no local system in any of these cities.

A Trenton, N. J., dispatch says that "an arrest on the charge of fraud has followed the appointment of a receiver for the State Telephone Company of New Jersey, which formerly issued $1,000,000 bonds and put up wires from Trenton to Jersey City, but never installed any service."

The People's Telephone Company, of Fall River, will extend its line from Fall River Mills, Cal., through Burney Valley to Montgomery Creek, down Oak Run to Millville, and then go to Redding by way of Palo Cedro. Bella Vista may also be included. The farmers of Oak Run are anxious to have the line go through and will lend financial assistance for its construction. This will mean the initiation of direct communication from Redding to Fall River Mills without any transfer of messages, and will be of great benefit to the public in general.

The Federal Telephone Company has notified its patrons and the borough officials at East McKeesport, Pa., that it intends to retire from business. The company asks for the repeal of the company's franchise in the borough and the surrender of its bond. The borough council will refuse to surrender the charter until a sufficient amount of money is deposited to defray expenses connected with legislation necessary.

At present telephone activity is very noticeable in the villages of Shortsville and Manchester, N. Y., and the surrounding country, and more telephones have been ordered than can be installed for some time to come. The Red Jacket Company, located in Shortsville, has a large patronage through both villages, and has several miles of rural service all through that vicinity. It is extending its lines daily, and is expecting to build seven miles of new line at once.

The Cecil Farmers' Telephone Company, of Elkton, incorporated by the last Legislature of Maryland, is building lines in the upper section of Cecil County. At a recent meeting of the stockholders of the company it was decided to increase the capital stock from $5,000 to $25,000.

A long distance telephone line from Decatur to Birmingham, Ala., is being constructed, a distance of 87 miles.

The Orange County, N. Y., Telephone Company is understood to be negotiating for the New Hampton & Bloomingburg telephone lines.

A dispatch from Vienna, Austria, states that automatic telephones have just been introduced among a limited number of subscribers in that city.

Two Nebraska Independent Companies Increase Capital.

The Platte County Independent Telephone Company has amended its articles of incorporation increasing its capital stock to the authorized limit of $40,000.

The Hastings Independent Telephone Company has increased its capital stock to $300,000 to provide for an issue of $150,000 of preferred stock, to draw 6 per cent. dividends annually.

The Ellis County Independent Telephone Company has now direct connection with Hillsboro, Waco, Houston, Austin, San Antonio and other South Texas points. A long distance line connecting Waxahachie with Waco was completed recently. The Independent has had connection with Corsicana two or three years. Material has been purchased for the construction of a line between Waxahachie and Fort Worth. When this line is built the long distance service will then be complete to St. Louis. This company has made several unsuccessful efforts to get into Dallas, and it yet hopes to establish a system in that city within the next year or two.

The Diamond State Telephone Company has begun the erection of a line between Elkton and Cowentown, Md. The company has lines running to almost every town and village in Cecil County, and has about 500 subscribers. Recently the line has been rebuilt between Elkton and Rising Sun and Cherry Hill and Elkton.

The Nicholas Telephone Selector Company, of Rochester, N. Y., has been formed to deal in electrical apparatus, with a capital of $10,000. The incorporators are Willard C. Rich, G. W. Rich and William H. Boutell, of Rochester; Charles E. Nicholas, Columbus, O.

An automatic telephone service, costing thousands of dollars, is being installed throughout the Solvay Process Works, and in the homes of the officers and employes in authority in various parts of Solvay and Geddes, N. Y.

According to the franchise given by the corporation board to the telephone company in Mohawk, N. Y., the rates can in no case be advanced from present prices, $12 for dwellings and $24 for business places, as they were said to be permanent when the franchise was granted

The Glen Telephone Company will on May 1 raise the rates of 'phones in Fonda, N. Y. All business 'phones will be $2 per month instead of $1.50 as at present. The price of the residence 'phones will not be increased, but they will only have the privilege of talking to residents in Fonda and Fultonville.

A farmers' mutual telephone company has been organized to furnish telephone service in Oceana County, Mich., at cost. The officers of the new company are: President, C. W. Taylor; secretary and treasurer, Roger Southwick; directors: Lucius Slocum and Kim Croff.

A stock company is being organized in Montrose, Miss., to build an Independent telephone system from Newton to Bay Spring, taking in Garlandsville, Baxter and Montrose.

Mortgage for $15,000,000.

A corporation mortgage for $15,000,000 has been given by the Independent Securities Company to the Security Trust Company, of Rochester, N. Y. The corporation has its home in Utica and includes nearly all the Independent companies in this State.

D. A. Reynolds, vice-president and manager of the State Line Telephone Company, has organized an Independent company at Peekskill, N. Y., to compete with the Hudson River Telephone Company. The new company will have its line in operation by July 1 and will reduce the price of 'phones to $18 per year. The company will have special fire and police calls.

The Arkansas City, Kan., Commercial Club has started a fight on the Missouri & Kansas and the Pioneer Telephone Companies, with the object of having the two companies, which are now understood to be under the same management, consolidate their exchanges, and relieve the patrons from the necessity of paying for two telephones, and also for the purpose of improving the service.

Citizens of Bloserville, Pa., and vicinity, have organized a telephone company, which will be known as the Bloserville Telephone Company. The company will begin the construction of a line from that place to Newville, where it will connect with the United Telephone & Telegraph (Home) lines.

The Oklahoma Rural Telephone Company, operating seven rural lines, and the Pioneer Telephone Company at Enid, Okla., have at last settled their differences and a contract has been signed whereby the patrons of the two systems are to have free exchange over all lines.

Gloversville, N. Y., is to have a new Independent telephone company. A canvass for subscribers was lately commenced, and it is the intention of the new company to form an organization and install a modern plant for the cities of Johnstown and Gloversville. LeRoy W. Stanton, an electrical telephone engineer, of Cleveland, O., is promoting the project.

The Providence, R. I., Telephone Company is to erect a telephone exchange at Narragansett Pier, and it is expected that it will be finished in time for the convenience of the summer patrons. The building is to be two stories high and a common battery board is to be installed.

Arrangements have been made by the New England Telephone Company, to extend its service at reduced rates for the benefit of the farmers at Amherst, Mass.

Telephone Incorporations.

The Danby Telephone Company, Danby, N. Y. Capital stock, $7,200. Incorporators: J. E. Black, Charles E. Bruce, C. F. Denman, all of Danbury.

The Watkins Telephone Company, Watkins, Minn. Capital stock, $10,000. Iocorporators: H. J, Wartman, J. P. Olson, H. J. Kainer and C. C. Vitrance, all of Watkins.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Bamberg, S. C.—The citizens have voted to grant a 30-year franchise to Messrs. Howell & Jordan for a waterworks system and electric lights.

Bellefontaine, O.—The citizens have voted in favor of issuing $50,000 in bonds for improving the municipal electric lighting plant.

Cleveland, O.—The People's Electric Lighting & Power Company, of this city, has been incorporated by H. T. Emerson, William Brodie and others. Its capital stock is $10,000.

Detroit, Mich.—At a recent special meeting of the council the by-law to raise $30,000 for the rebuilding of the electric plant was passed provisionally, and will be voted on along with the other by-laws May 12.

Douglas, Ga.—Superintendent Putzel is rushing the work of wiring the streets and buildings, and within a short time this city will be fully equipped with electric lights.

East Hampton, Mass.—The directors of the East Hampton Gas Company will install a new electric lighting plant here.

Far Rockaway, N. Y.—The work of installing electric lights in the Wave Crest section will begin in a few days.

Goldendale, Wash.—H. W. Fellows, an electrical engineer of Spokane, has applied to this city council for an electric light franchise.

Hampton, Ia.—L. A. Little, of this city, has traded a farm of 1,200 acres for the electric lighting plant at Missouri Valley, the amount involved being $18,000.

High Point, N. C.—The High Point Ice & Fuel Company, with a capital of $125,000, has been incorporated by Charles Behee and W. G. Burnett, of Atlanta, and Westcott Robertson, of this place, to conduct a general electric lighting business.

Kelso, Wash.—The town council has granted a franchise for electric lighting to the Kelso Water & Light Company

Madison, Mo.—The election to vote on the issuance of bonds to the amount of $5,000, for the erection of an electric light plant, was lately carried.

Melrose, Minn.—A special election will be held April 29 to decide whether or not to issue electric light and water bonds.

Miamisburg, O.—The board of public affairs has instructed the clerk to advertise for bids for the construction of a new electric light plant in this city.

Newark, N. J.—The New Jersey Beck Electric Lighting Company has been incorporated here with a capital of $125,000. The incorporators are Charles A. Woodruff, Thomas J. Butler and Eli Teeter.

Paterson, N. J.—The Paterson Electric Light, Heat & Power Company has been incorporated with a capital stock of $500,000. The new company will be the most formidable rival of the Lighting Trust in this State, as it is the intention of the stockholders to extend the business outside of this city.

Pine Bluff, Ark.—The St. Louis Southwestern Railroad Company will install an electric lighting plant in its shops. Harry H. Sanborn, an expert electrician of St. Louis, will superintend the work.

Sanborn, Minn.—The citizens have voted the issuance of $6,000 bonds to install an electric light plant.

Shelbyville, Tenn.—The Legislature has passed an act authorizing the board of mayor and aldermen of this place to issue bonds aggregating $40,000 to buy an electric light plant and waterworks system.

Walker, Minn.—The citizens have voted to issue bonds for an electric light plant.

Wasco, Ore.—The city council has ordered a special election to be held May 10 to vote on the question of issuing bonds in the sum of $23,000, to be used for the installation of an electric light plant, sewerage and water system.

Williston, N. D.—The citizens have voted to bond this city in the sum of $27,500, for the purpose of constructing a system of waterworks and an electric lighting plant.

Wisner, Neb.—A special election is to be called to vote on the proposition of issuing $9,000 worth of bonds to construct an electric light plant.

STREET RAILWAYS.

Albert Lea, Minn.—The Collins Construction Company is now preparing plans for a trolley line to run from this city to St. Cloud.

Alexandria, La.—A largely attended meeting of citizens was held here a short time ago to listen to the proposal of T. G. Bush, of Mobile, and G. N. Borde, of New Orleans, to establish an electric line. The promoters were assured of a franchise and assistance on the part of the citizens.

Ashland, Va.—The electric car line between Richmond and this city, is now an assured fact.

Bunker Hill, Ill.—There has been organized here the St. Louis, Bunker Hill & Eastern Traction Company, with the purpose of building and operating an electric line from East Alton to Litchfield. J. H. Belt, Jr., is president and W. B. Powell, secretary.

Frederick, Md.—The Maryland Construction Company, a corporation formed for the purpose of constructing an electric railway between Baltimore and this city, has acquired 60 acres of land near the Monocacy River near Ceresville, a couple of miles north of here. It is understood that the land is to be used as a site for the power plant of the railway.

Gallatin, Tenn.—The friends of the proposed electric railway from this city to the Cumberland River and Castalian Springs held a recent meeting with 15 additional advocates of the enterprise, to form a plan to immediately organize and elect officers for the purpose of acquiring right of way and making a survey of the route over which the line will run. Temporary officers have been elected as follows: Charles A. Whitesides, president; W. G. Schamberger, vice-president; William Hall, treasurer, and E. O. Buchanan, secretary; committee on right of way, C. H. Fiddler, E. E. Chrisman and J W. Carmichael.

Greenfield, Ind.—A "cross-country" electric railway is proposed by a company organized to build from Fortville to Shelbyville, through Maxwell to this place and Fountaintown. The promoters are M. B. Walker, of Fortville; J. M. McCreery, of Indianapolis; Arthur Jones, of Alexandria; Edwin Downey, of Anderson, and W. A. Hough, of Greenfield. It is said that the line has already been surveyed from Fortville to Greenfield.

Sayre, Pa.—The council has voted to grant the request of the Sayre & South Waverly Electric Railroad Company for a franchise and privilege to build an electric road through the borough.

Ticonderoga, N. Y.—There is a movement in progress for the construction of an electric railway in this vicinity. Capitalists of Troy, N. Y., and Vermont, are said to be considering the plan. The proposed road, it is said, will be 14 miles long, running from Hague to Baldwin and hence to Addison Junction and connecting with the Rutland Railroad system. It is said that the ultimate extremity of the road would be at the end of Lake George, where connection with the Hudson Valley Road would be made.

Walla Walla, Wash.—There is an electric line proposed that will connect this city with the Columbia River at Wallula.

Webster City, Ia.—Lester Gailey, an Eastern promoter, is in this city to interest local business men and capitalists in a proposed electric line from Fort Dodge to Webster City and thence south to Des Moines. He roughly estimates the cost of such a line at $20,000 per mile, including all equipment.

POWER PLANTS.

Jackson, Mich.—The Commonwealth Power Company is preparing plans for a $100,000 power plant to be built here.

Williamsport, Pa.—An official of the combined electric companies of this city lately made the statement that the proposed big power plant will be built during the coming summer.

York, Pa.—The much talked of electric power plant on the Susquehanna River, near McCalls's Ferry, York County, looks like an assured fact, since the New York capitalists have agreed to furnish the money when a favorable report has been made by the engineers. It is said that $10,000,000 will be forthcoming if the engineers make a favorable report.

BIDS WANTED.

Binghamton, N. Y.—Sealed bids will be received by the city clerk until May 8 for lighting the city streets with electricity.

Joplin, Mo.—The board of public works of this city will advertise for bids for the construction of betterments and the addition of equipment to the city lighting plant; the capacity is to be more than doubled. Improvements will cost $30,000.

Port Arthur, Ont.—Sealed bids will be received until May 5 by the chairman of the electric railway and light commissioners for the purchase of the following electrical machinery: One 150 hp. Wheelock compound condensing engine; one 80 hp. boiler, shafting, pulleys and belting; one 500 volt. 45 kw. railway generator; one 60 kw. 2,000 volt, 125 cycle alternator, with all necessary switchboard and attachments. J. McTeigell, secretary of the electric railway and light commissioners.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 15@15⅛c.; Lake 15⅛@15¼c.; casting, 14¾@14⅞c.

The New York, New Haven & Hartford Railroad Company has bought the Suffield (Mass.) Street Railway for $75,000.

The regular quarterly dividend of 2 per cent., declared by the directors of the Chicago Edison Company, will be payable May 1.

A dispatch from Schenectady says the pay roll of the General Electric Company's plant in that city is now the largest in the history of the company.

The Providence & Burrillville (R. I.) Street Railway Company has issued $750,000 five per cent. 20-year bonds and will double-track 20 miles of main line.

A reorganization committee of the Eastern Ohio Traction Company has requested holders to deposit their securities for the purpose of effecting a reorganization.

The United Metals Selling Company has made a reduction of ⅛ cent in the price of refined copper, which is the first change that has been made for several months.

The Hewitt Motor Company of New York was recently incorporated at Albany with a capital of $100,000. The directors are E. R. Hewitt, Erskine Hewitt and C. O. Snyder, New York.

It is expected that the bonds of the Keystone Telephone Company of Philadelphia, which are being underwritten, will be allotted by May 1, and all arrangements completed for placing them.

The American Light & Traction Company has declared the regular quarterly dividend of 1½ per cent. on its preferred stock, and a second semi-annual dividend of 1½ per cent. on its common stock, both payable May 1.

Stone & Webster of Boston report a semi-annual dividend of $5 per share, payable May 15, on the capital stock of the Tampa Electric Company, to stock of record May 5. Books close May 4 and reopen May 16.

The New York State Board of Railroad Commissioners has authorized the Rochester Railway Company to increase its capital stock from $5,500,000 to $6,000,000. The increased capital is stated to be needed for new construction and reconstruction.

A special meeting of the stockholders of the Montreal Street Railway Company has been called for May 8 for the purpose of voting on a proposition to issue $1,000,000 of 4½ per cent. 20-year bonds, the proceeds of which are to be utilized for extensions, improvements, increased electrical power facilities, etc. The new bonds will be issued to stockholders at par. The present bonded indebtedness of the company amounts to $2,473,000, and the capital stock is $6,600,000.

It is reported in Wall Street that the annual report of the General Electric Company will not be as good as some people expected. Last year the profits of all manufacturing companies were smaller than the previous year, and, while the business of the General Electric Company was comparatively well maintained, prices were lower in many instances and business restricted, and this condition will be reflected in the annual report covering the last fiscal year. It is feared in some quarters that a trade contest with the Westinghouse Company and with the Allis-Chalmers Company (the latter having spent $3,000,000 in extending its plant to compete with both General Electric and Westinghouse), foreshadows still smaller profits in the future.

EDITORIAL NOTES.

The General Electric's Annual Report.

The annual report of the General Electric Company was made public on Friday last, and it shows that the gross earnings of the company last year were about $2,500,000 less than the previous year and the orders received were $4,000,000 less.

The total profits of the company, less the debenture interest, but prior to the drastic writing off for depreciation of factory plants, patents, etc., were equal to 17.61 per cent. on the capital stock of $48,247,943, against 22.38 per cent. on the capital stock of $43,866,700 in the previous year. After all charges and writing off, the balance applicable to dividends on the $48,247,943 capital stock was equal to 12.35 per cent., as compared with 14.40 per cent, on $43,866,700 capital stock in the previous year.

Third Vice-President E. W. Rice, Jr., notes in detail in his report the engineering results of the year. He says that the commercial success of long distance transmission systems is generally recognized and the number of such undertakings has increased. One interesting instance of the constantly increasing number of applications of electric motors is that of the high-speed electrical motor centrifugal pump, which promises to replace the steam pump for supplying water to cities. This electric pump occupies about one-quarter the space, costs much less and is more efficient than the present steam pump. Mr. Rice says that the combined turbo-generator has such manifold advantages in economy, reliability, simplicity and low cost that it is certain to replace all other forms of steam engines in generating electricity. The new alternating current motor, he says, has been successfully employed on two tramways, and numbers of additional orders have been received. The report further says: "Our inventors have been actively at work for several years to discover more efficient and better methods of electric illumination than the present carbon arc and incandescent lamp. As a result, this last year we have introduced the 'magnetite' arc lamp, which gives a light equal to the present carbon arc with about one-half the consumption of energy, and have also made important improvements in the economy of the incandescent lamp."

Of the work of electrifying steam railroads, the report says:

"The electrical work of the New York Central Railroad has excited much interest among the officials of other railroads, and from the numerous inquiries and requests for plans and estimates which we receive, it is evident that we are entering upon a most interesting phase of electrical development in connection with steam railroads, and that it will not be many years before all suburban trains in the vicinity of our large cities will be operated by electric power."

President Coffin summarizes the report as follows: "While our total business was less in 1904 than in 1903 in money value, the number of contracts and orders was greater, resulting in more work for the organization."

* * *

Instructors in Engineering and the Carnegie Pension.

Philanthropy is the sublime art, and its benefactions have extended to the inner sanctum of academic life. Mr. Carnegie has made millions out of the technical knowledge of his colleagues and is spending them like an intellectual king. Neither is he neglecting, so to speak, his co-workers, their children or their children's children. To them he is offering the gift of knowledge, which leads to independence, and thus is intensifying the spirit of Americanism in its highest sense. And this gift of knowledge, laid at the door of every workman by the spread of great technical schools, is not to be the means of adding misfortune to the lives of those entrusted with the task of transmitting this knowledge. They have not been forgotten, they will not be forgotten, when old age and decrepitude lay weighted hands on their feeble forms. The new plan outlined and crystallized by the munificence of Mr. Carnegie will give them financial support in their declining years—and the links of reasoning which connect the labor of the pedagogue with the wealth of the steel king are readily made self-evident. A teacher of pure or applied science is fitting men for the task of earning a living in the world. The industralism so characteristic of American life calls for an unusual army of technicians. Gigantic schemes are projected whose pilots, captains, lieutenants and other workers must undertake purely technical responsibilities. Those whose early lives have been moulded by the influences of technical training occupy all positions from the bottom of the ladder to the top. In large or small electrical establishments this is emphatically true, and many large corporations devoted to the design and construction of electrical equipments request in their printed application blanks for positions, knowledge of what technical school the applicant is from. These graduates become the builders of great fortunes either for themselves or for others. They become the competitors of their own instructors, who might perchance find a better field in practical life for their talents than teaching. Mr. Carnegie owes his wealth to technical knowledge fundamentally, although the financial co-operation of great concerns lifted these great steel industries from the shadows of simple manufacturing life into the bright light of public observation. The preliminary school for industrialism is the technical school, and the protection afforded in their old age to the instructors thereof will drive away many of the disturbing worries presented by a review of the possibilities of the future.

A fund of $10,000,000, the interest of which at 5 per cent., or $500,000, with which to ease the last years of merited repose of our teachers in technical schools and colleges, rises before the mind's eye as a splendid act of exalted philanthropy.

Many of our teachers and professors of electricity who have yielded up their life's fiber in imparting instruction in this science will be benefited by this donation. With this provision in store for them their work will be rid of unpleasant thoughts of the future.

How strange it seems to know that the profession of teaching is poorly paid, so badly, in fact, that out of the small salary it yields it is not expected that the instructor can save enough to secure future independence. Millions are spent on magnificent temples of learning, but the power and brains that give them a name in the world remain as of old the recipients of barely a living. It has taken Carnegie, the man of heart and intellect, to recognize this fact.

Another Reduction in Telephone Rates.

The fight which has been waged for years against the exorbitant rates of the New York Telephone Company has not been barren of results. Beginning June 1 another reduction in rates will go into effect. The latest concession, however, only benefits a certain class of subscribers, namely, large establishments, such as hotels, brokers' offices, etc., or senders of more than 3,600 messages annually in Manhattan. The present rate for the above number of messages a year is $240 while the new rate will be $216.

As announced by an officer of the company the mileage charges for circuits connecting station of the premises to private branch exchanges, or for tie lines connecting one private branch exchange with another, which heretofore have ranged from $60 to $84 per mile, have been reduced to range from $48 to $60 per mile.

The charges for circuits crossing the North River (when used for connecting extension stations to a private branch exchange or for tie lines) which heretofore have ranged from $204 to $300 per circuit, have been reduced to range from $180 to $240 per circuit.

The charge for local messages from private branch exchanges in excess of 3,600 will be as heretofore, 4 cents each, or, when contracted for in advance, in lots of 400, $3 per hundred.

The charge for an auxiliary line and stations—i. e., a second line supplementing a direct line—which heretofore has been $48, has been reduced to $36 per year.

From this it will be seen that the monopoly has condescended to reduce its charges in this case from 5 to 10 per cent.

But allowing for the concessions already and about to be made there will be little danger of the company going into the hands of a receiver and it will not be necessary to omit declaring a dividend on its stock.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

The annual meeting of the General Electric Company will be held in Schenectady, N. Y., May 9.

Mr. Marconi is at present in Cape Breton watching the progress of the construction of his new wireless station.

The Stevens bill presented to the New York Legislature Monday night provides for 75-cent gas and 10-cent kw.-hour electricity in New York, also adequate inspection of quality and pressure, the repeal of the law authorizing the formation of the lighting combine, and the creation of a State board to supervise all lighting, telephone, telegraph and transportation companies.

Mr. George F. Porter, master of transportation for the National Electric Light Association, has appointed Mr. Charles H. Hodginson, of the Boston Edison Company, to look after transportation matters in New England in connection with the coming convention at Denver-Colorado Springs, June 6 to 11.

The wages of the gatemen and guards in the employ of the Interborough Rapid Transit Company of New York have been advanced from 10 to 15 cents a day, according to the length of time they have been on the payrolls. The order went into effect May 1.

A cable dispatch from Berlin says the International Congress, called to celebrate the tenth anniversary of the discovery of the Roentgen ray and to collate the latest applications and developments, opened in that city on Sunday and will continue in session the greater part of this week. Prof. Roentgen is present. Among the Americans attending the Congress are Dr. Leonard of Philadelphia, Dr. George Kunz of New York, and Dr. Rudisjicinsky of Cedar Rapids, Ia.

The next meeting of the Chicago branch of the American Institute of Electrical Engineers will be held on May 23. Mr. J. R. Cravath will read a paper on "Light Electric Railways."

FARMING BY ELECTRICITY.

BY A. FREDERICK COLLINS.

That great peninsular stretching southward between the Adriatic Sea and the western part of the Mediterranean, and which is bounded on the north by the Alps, separating it from Austria and Switzerland and from France on the west by the Maritime Alps, is remarkable for the fertility of its soil and famous for its gigantic water powers.

For this reason Italy is a country teeming with agricultural interest and hydraulic power developments, the latter having in recent years been utilized extensively for the generation of electricity, and the fecundity of its soil is only excelled by its growth of hydro-electric plants.

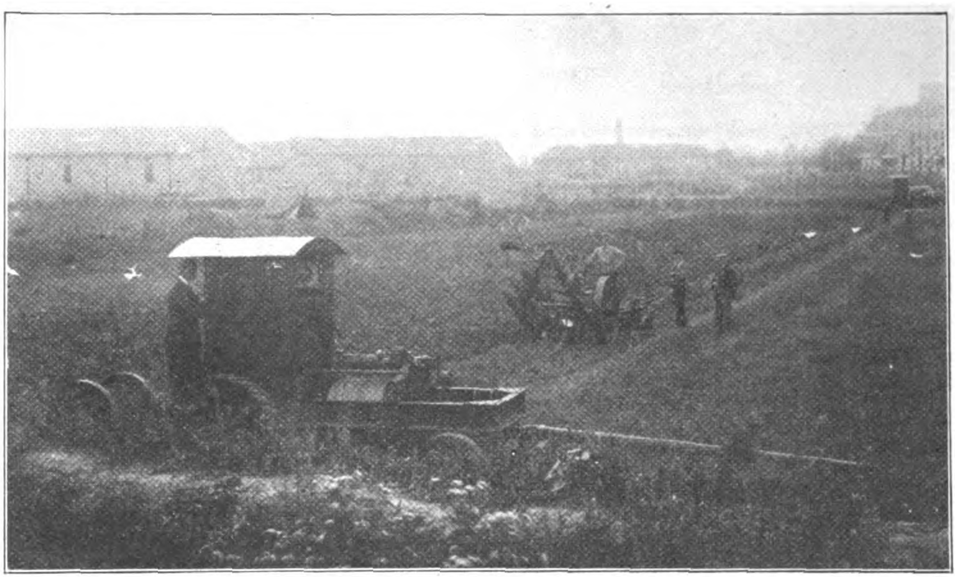
From these great hydro-electric central stations, located at the very head of natural sources of power, many thousand kilowatts are sent through overhead high-tension lines across the fertile fields, rendering feasible the application of electricity to agricultural pursuits easy of accomplisment and economical in its results.

Since hydro-electric power can be obtained at exceedingly low prices—much lower in fact than in the United States—it is evident that these domestic applications, which have practically just begun, shall in the immediate future be greatly extended, and even now manufacturers of farming machinery are designing and building special machinery for the utilization of electricity instead of animal and other tractive powers.

In Turin, the Societa Elettrotecnica Italiana, one of the most important companies building electrical machinery in Italy, has become deeply interested in this basic problem and is now developing a full line of farm machinery, the result thus far seeming to point to the final elimination of the ox and horse as a factor in the tillage of the soil. As the fundamental operation of turning up the soil has, where animal power was used, been the most tedious as well as requiring the largest expenditure of power in agriculture, the advent of any means to lighten the labor and decrease the expense must be hailed with interest.

On this primary and important work hinges to no small extent the products of the field. In England, Germany and America steam cultivating machinery is in extensive use; in the steam system gigantic plows that will turn from three to five furrows at a time are connected up to a traction engine which draws the implement from one end of the field to the other and then back again. While the plows are made so that they need not be turned around and the engine runs with equal facility in either direction, there is a considerable amount of time lost at either end in uncoupling the plow and manœuvring the engine.

Notwithstanding this untoward feature steam power in husbandry has proven of great value on large farms, for the agriculturist is made more or less independent of the seasons and is enabled to get in his seed at more nearly the proper time and to do away with a large number of horses, applying the food they would consume to more profitable places. Besides plows, harrows, cultivators, harvesters and other implements for quick work have been designed for operation by steam and have proven successful in every way in the countries where they have been used; but steam machinery is not very economical in a country where coal is expensive and labor and water power cheap.



Electrically-Operated Plow at Work.

The Societa Elettrotecnica Italiana has taken cognizance of the facts and in the electric plowing system devised by it has fully met the conditions, both agricultural and electrical, of that country alone, but there are many places in the far West of the United States where the same method could be used with excellent results, as, for instance, in the sun-baked but fertile valleys of Southern California.

The Italian system consists of two electric winches mounted on separate trucks and these, when the field is to be plowed, are placed opposite each other when they are connected together by means of a steel cable of small diameter. The plow used is of the Fowler type, similar to those employed for steam plowing, except that it is not quite so heavy, but it is balanced and made double and this is coupled to the transmission rope which is carried in either direction by means of winches.

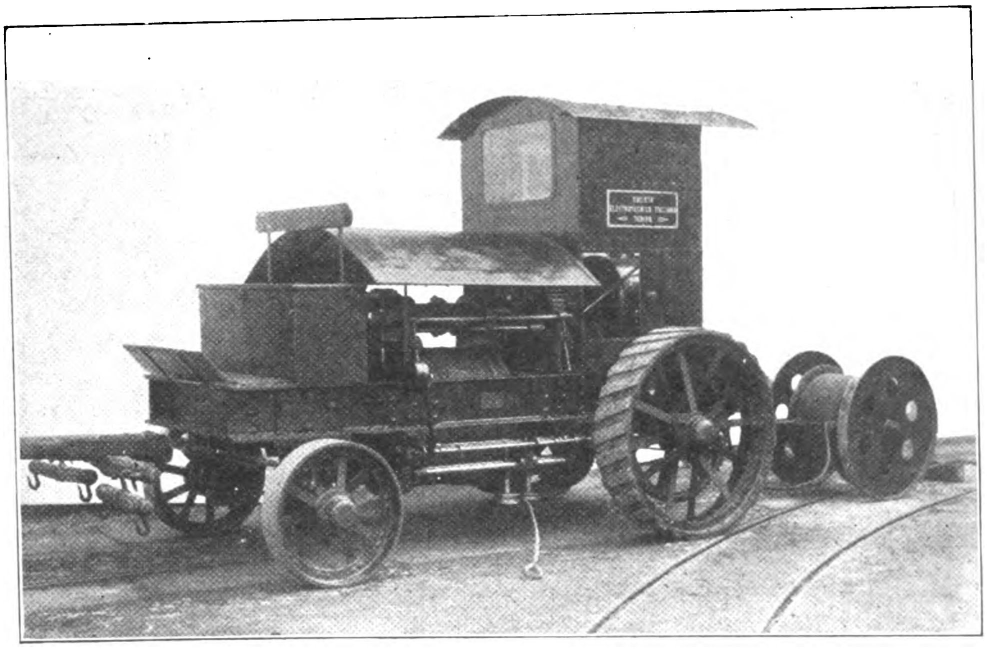
The winches are operated electrically by an induction motor which transmits its power to the drum of the winch-rollers through the medium of a reduction gear. The motor of each outfit is of 20 hp. and develops a cable speed of 50 meters when the plow is cutting furrows to a depth of 25 cm. By reducing the speed of this motor the depth of the furrow may be increased to 60 cm. (about 2 feet), which is the limit prescribed in that country.

To change the speed the winches are equipped with interchangable gears making it possible to run at 0.80, 1.20, 1.60 or 2 meters per second and in this way the most variable conditions of the soil are met. There are devices mounted on the truck for winding the rope on the drum evenly during the traction of the plow and for braking the drum at the moment of stopping.

There are also automatic arrangements for braking the current when the plow is at the end of the run so that the grossest carelessness of the employes cannot cause a collision of the plow and the winches. When the run is completed, the balance plow is instantly shifted and the opposite drum begins to do its work, carrying the plow back again. The trucks are equipped with small switchboards, carrying all the controlling apparatus necessary for the motor.

Though horses are employed to draw the trucks where any considerable distance is to be traversed, the trucks are arranged with wide traction wheels which are operated by the motor, so that it follows progressively and automatically the plow as the latter changes furrows.

The handling of the whole portable installation is very easy and the operation of propelling the plow through a length of furrow of 350 meters and getting the plow ready for the return trip consumes only about eight minutes. Therefore if it were possible to work without interruption at this speed and plow three furrows at a time it would require about four hours to plow one hectar (equal to about 2½ acres. This speed is more than eight times that which can be obtained by animal traction and the depth of the furrow is much greater, and naturally the plowing by means of the former is vastly superior to that of the latter.



Electric Winch Used in Plowing.

The current is conveyed to each of the two electric windlasses from the overhead transmission lines and a special system of movable contacts are connected to a flexible cable wound upon a reel and carried on wheels. These flexible conductors give the plow a wide latitude and hence the apparatus can be worked in any vicinity where current can be had.

A high-potential oil-insulated transformer is also provided to step down the voltage from the high tension lines to a value suitable for the local lines. The simplicity of all the individual devices which goes to make up the electromechanical units for the system of electrical plowing make it especially valuable, for the trucks are usually operated by ordinary workmen who are not at all skilled in the art. Another feature worthy of mention is that the different parts are easily get-at-able and this is important in a class of apparatus constantly exposed to the variations of the weather.

Again the same trucks can be used for many other purposes on the farm, as, for instance, in combination with harrows and harvesters, and during the winter they find a ready application for sawing wood, pumping water, churning, etc.

A pair of these winches can be kept almost constantly at work during the entire year on every farm of any considerable size to an advantage, and its economy can easily be calculated providing the two following factors are known—the price per kilowatt of electrical energy and the wages of three farm-hands, which of course vary in different countries and in the same country under dissimilar conditions.

* * *

THE ARNHEIM PARTY-LINE TELEPHONE SYSTEM.

A most ingenious development of the party-line telephone system has been worked out by Prof. Paul Arnheim and is now being placed on the market in England by the Berliner Telephone Manufacturing Company. By a party-line is meant a telephone line shared by several subscribers, and provision must be made for "selective ringing"—that is to say, for calling up any one of the subscribers without disturbing the others. On the postoffice and national telephone exchanges in this country this selective ringing is provided for by connecting the subscribers' bells either between the A line and earth or the B line and earth, and by giving the bells a "bias" for positive or negative currents, so that four subscribers may be placed on a party line if necessary without the introduction of a code of ringing signals. This has the disadvantage, however, that any subscriber can cut-in and listen to or take part in the conversation of another subscriber. The main object of the Arnheim system is to remove this defect without having recourse to the complicated "lock-out" systems which have been tried from time to time in the United States. Another object is to increase the number of instruments which can be connected to a party-line.

Each party-line terminates at a selector switch, to which all the subscribers' instruments are connected. When one of the subscribers wishes to use the line, he depresses a button and removes his telephone from the hook. This sets the selector switch automatically so as to connect his instrument to the line and leaves the other subscribers disconnected and the rising of the button shows him that he is through to the line. The subscriber then rings the exchange. Should any other subscriber try to get in while the first subscriber is still on the circuit, his button does not rise after it has been depressed, showing that the line is engaged. The automatic switch works in such a way, however, that his instrument is connected to the line as soon as the first subscriber clears by hanging up his telephone.

In connection with the instruments at each operator's position at the switchboard is a "selector disk" with a number of finger holes in it, corresponding to the number of subscribers on the party line. To ring up one of the subscribers, the operator, having plugged into the jack in the usual way, places her finger in the hole marked with the subscriber's number and pulls the disk round. This sends a number of impulses corresponding to this number to the automatic selector switch, already referred to, which connects the subscriber in question to the line.

We had an opportunity of inspecting an installation for a 10-subscriber party-line this week, and were able to see these successive operations carried out. To give a more detailed account of the system, we add a diagram (Fig. 1) applying to a magneto exchange. It may be mentioned, however, that the system has also been fitted on a central-battery exchange—in fact, one is under trial by the National Telephone Company at its Holborn exchange, the party-line serving some of the offices of the heads of the engineering departments at the company's chief office.

On subscriber 2 depressing the button N (the position of this button is seen at

---

* From the "Electrician," London.

N_1 on the instrument of subscriber 1) and removing his telephone from the hook, he places his own A line to earth through the releasing coil R. At first this coil is not energized as there is a high resistance in circuit, and the button is retained by a clutch. A circuit is formed through the spring at F corresponding to this subscriber's instrument to the bar upon which it rests and thence through the relay R_1 (which has a resistance of 1,000 ohms) to the actual A line and through a pendulum contact and battery at the exchange to earth.

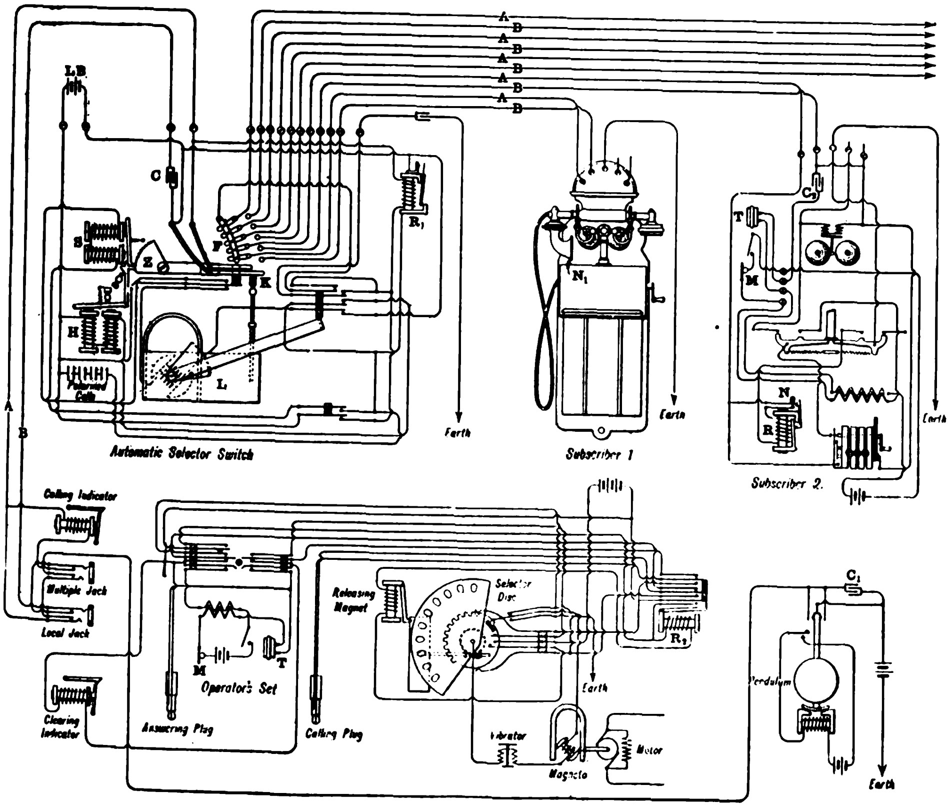


FIG. 1.—DIAGRAM OF CONNECTIONS.

The tongue of the relay oscillates backwards and forwards, and a current impulse is sent from the local battery LB through the step-by-step electromagnet H. This moves the ratchet Z, causing the arm K to travel over the spring contacts above it. As it moves along, it disconnects the subscriber's line springs one by one from the common bar, and as soon as it reaches the spring corresponding to the subscriber who is called, it breaks the coil-circuit of the relay R_1. As this relay is no longer operated the arm cannot travel any further and stops at this position, connecting both the A and B line to the corresponding lines leading to the subscriber's instrument. The B line is connected through a condenser C. As the A line is now connected direct to the subscriber's line instead of through the resistance of the relay R_1 sufficient current flows through the releasing coil R in the subscriber's instrument to release the button N, and the earth connection is at the same time removed from the loop. The subscriber now is connected to the exchange and his ringing current passes through the indicator which is bridged across the A and B lines. As soon as the operator plugs into the jack she cuts off not only the calling indicator but also the pendulum circuit.

It should have been mentioned that as soon as the lever K starts moving the arm of the second mechanism, L, is released and drops slowly, opening the contacts seen above it, one of which is included in the circuit of the relay R_1. At the end of its travel (which occupies 50 seconds) the lever L closes the two contacts below it. If now another subscriber plugs in, nothing further happens after he presses his button N, for the circuit of the relay R_1 is open on these upper contacts. When the subscriber has finished speaking he hangs up his receiver and the bell coil is placed across the line. This closes the circuit through the A line to the relay R_1, and thence through the bottom contact closed by the lever L through the local battery LB and back to the B line at the selector switch. The secondary contact of this relay now closes the circuit of the releasing electromagnet S, which allows the ratchet Z to fall back to its initial position; and when the arm drops the circuit of the coil L is also closed, so that the arm of this mechanism is raised to its normal position. When the arm has risen to its top position and is locked there, it opens the circuit of its own coil by means of the contact immediately above it. Everything is thus restored to its normal position.

A point worthy of notice is the introduction of "polarized cells" with aluminum electrodes to take the induction current on breaking the inductive circuits in connection with the local battery, and so diminishing the report heard in receiver.

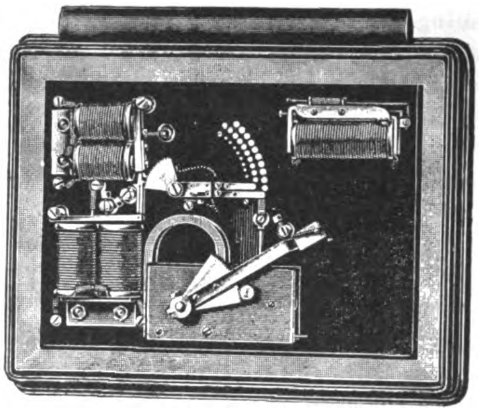

FIG. 2.—AUTOMATIC SELECTOR SWITCH.

We have now to consider the process of calling up one of the subscribers from the exchange. The jack of the subscriber being plugged with the calling plug in the usual way, the operator pulls over the disk selector, as already explained, and then momentarily presses to the left the ringing key seen above the operator's

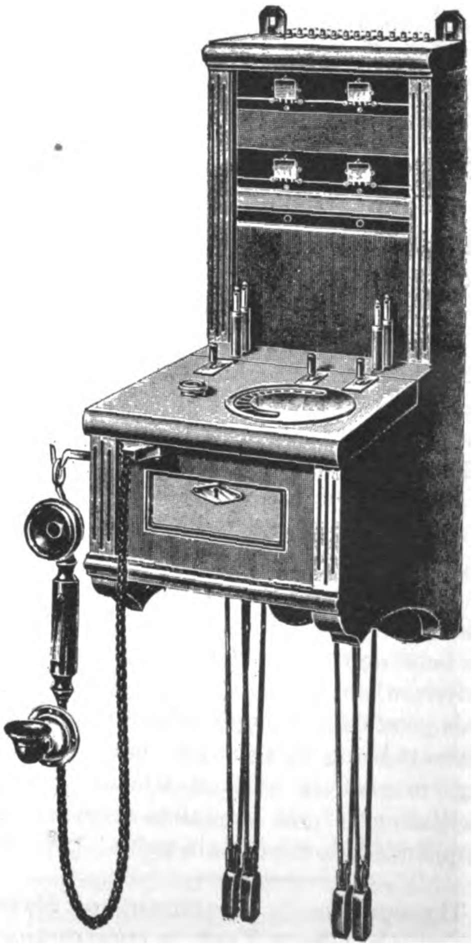

FIG. 3.—SMALL EXCHANGE FOR FOUR LINES.

set in Fig. 1. The disk selector stays in osition until the ringing key is pressed. The circuit of the retaining coil R_2 is then closed through the battery B and the releasing magnet, and as the disk flies back it closes a succession of contacts, sending impulses from the magneto over the A line through the coil R_1 controlling the automatic switch. The arm of the switch is therefore moved up to the position corresponding to the number of the subscriber wanted, and at the same time the arm of L starts traveling downwards. As soon as the selector switch makes contact with the subscriber's instrument, the disk selector, just before reaching its zero position, sends a ringing current from the magneto through the loop for a few seconds. A vibrator at the operator's position shows that the bell is ringing. If the subscriber does not answer, the operator can ring again with her ordinary ringing key. As it takes 50 seconds for the arm of the lever L to drop, after this period she no longer rings the subscriber unless she turns the selector disk again. The period of 50 seconds is selected to give the subscriber time to answer the call.

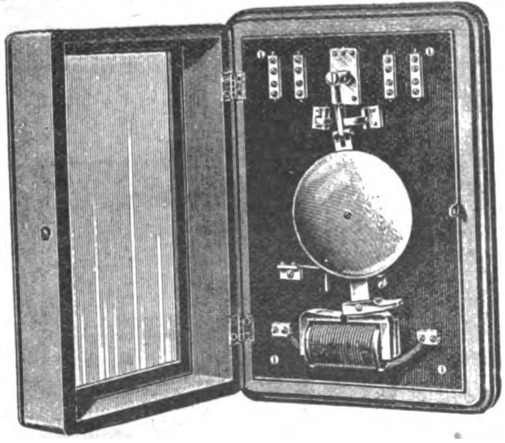

Fig. 4.—Electrically-Controlled Pendulum.

Fig. 2 shows the automatic selector switch, the relative positions of the various parts being the same as shown in Fig. 1. Fig. 3 is a small exchange for four lines and shows the relative size of a selector disk and Fig. 4 is the pendulum for sending the impulses to the selector switch when the subscriber is calling. This pendulum is electrically driven, the contacts being so arranged that the driving magnet is excited whenever the oscillations of the pendulum decrease in amplitude below a certain point.

The equipment department of Mare Island (Cal.) Navy Yard is constructing two sets of the Lodge-Muirhead system of wirelsss telegraphy which will be installed at Honolulu and Guam under the direction of the Navy Department.

ELECTRICITY LEAFLETS.

BY NEWTON HARRISON, E. E.

ELECTROPLATING.

The Deposition of Metals.—The general process of depositing metals by means of electricity has developed into an industry represented by several distinct branches. Each of them is of importance in the commercial world and covers the fields respectively of:—

1. Electroplating.
2. Electrotyping.
3. Electro-metallurgy.

Electroplating.—This process might be defined as one in which a thin layer of metal, such as copper, nickel, gold or silver, is deposited by means of electricity from appropriate solutions called plating baths. The thickness of metal deposited is known in the case of those that are termed precious, as gold and silver, and in consequence expressions are used such as triple or quadruple plate, etc.

Electrotyping.—The common expression, electrotype, is employed in all printing and publishing houses in connection with the duplicates of photo-engravings, used so extensively in this class of work.

An electrotype therefore is the exact duplicate, or as some term it, *fac-simile* of such cuts or engravings as would be endangered by use in printing. These facsimiles are obtained by a plating process finally, though certain important preliminary processes are necessary. The name was probably derived from the practice of taking a wax impression of type and plating this impression with copper; hence the term electrotype.

Electro-metallurgy.—The refining of copper and other metals cannot be better done than by means of the electric current. Instead of delicate preparations being made for a thin film of metal, as in the last two cases, the current is utilized for the purpose of separating the pure metal from all impurities and depositing it in thick plates at the cathode. The anode would therefore be the crude ore, probably in the shape of a block, dipping of course in the correct solution. Although this process is much more magnified than either of the last two, it is evident that it does not differ essentially from either, though the skill required in each case is of an entirely different character. The last is more associated with mining plants, particularly of copper ore, while both electrotyping and electroplating are fine arts.

Principles of Plating.—That which might be outlined as the principles of plating would embrace questions of correct current, electromotive force, solution and certain preparatory processes. In other words, the current must not be too strong and in addition the EMF. must be capable of carrying the metal over. Cleanliness is an important item in this process as the pressure of oil or grease in any form will prevent the cathode from receiving its proper coating. The principles of plating can therefore be best defined as follows:

1. Current of the proper strength per unit area of cathode.
2. Voltage suitable for the metal to be plated.
3. A solution electrolytically correc for the deposition of the metal at the anode to the cathode.
4. A perfectly free surface at the cathode with no traces of oil or grease.
5. A uniform current and EMF.

In all arts, human skill, which is the direct result of extensive experience, is rarely if ever limited in its exercise by set rules. In electroplating, skill of this character has developed to a high point and it may be considered as relating to two important features of the work as follows:

First—Skill in the mixing and preparation of solutions.

Second—Skill in the adjustment of the amperage and voltage employed.

It is necessary to consider the solutions from which various metals can be obtained by plating. These, as in the case where alloys are deposited, are only produced as the result of great knowledge of the art of plating. The dynamo has displaced the battery in the art of plating and electrotyping, though small equipments can be purchased which are only operated by a few cells. A shunt wound dynamo is generally employed whose voltage can be readily varied from 10 or 12 volts to 3 or 5 by means of the rheostat in circuit with the field winding. By this means the pressure can be adjusted to suit the metal to be plated over.

Plating Solutions.—The plating solutions in greatest use to-day are gold and silver among the precious metals, and copper, nickel and the alloy brass among the baser metals. The basis of these solutions are metallic salts manufactured with reference to the object in view and therefore called plating-salts.

Copper Plating Solution.—Too great a density in the copper solution must be avoided or the deposit will be brittle and crumbling and in addition very slow in making its appearance. A strong, tough deposit is obtained by a current of about 15 amperes per square foot of cathode surface. This solution may be made up either acid or alkaline. If acid, the deposit cannot be had upon iron or any other metal affected chemically by the acid. The following is an acid solution: "Prepare a saturated solution of copper sulphate by pouring hot water on the crystals of nearly the bulk required; add to this for each gallon of solution, a quart of water, and finally stir in for each gallon of solution four ounces of sulphuric acid. In the preparation of the solution it should be noted that by "saturated" is signified that state of the liquid when it will not dissolve any additional salt. The crystals may be dissolved in a separate vessel and then poured into the depository trough, or the trough may be nearly filled with warm water and the crystals dissolved into it from a few muslin bags suspended in the liquid. The water used must be either distilled or filtered or at least the solution filtered when complete. This solution is well adapted for most purposes of the electrotyper and has been tested repeatedly. It will deposit well upon metals or upon blackleaded moulds, and will be found to dissolve the anode freely when the current is passing. Some electrotypers use a large percentage of sulphuric acid, but this is seldom required except in very cold weather."—From Urquhart's Electrotyping.

An alkaline copper solution suitable for deposits upon iron, zinc or pewter, is here given: "Prepare a solution of copper sulphate, and also one of cyanide of potassium: add the latter to the former when a copious deposit of copper cyanide will take place. The liquid should be poured off and the residue washed, when it may be finally dissolved in a fresh solution of cyanide of potassium (two pounds to the gallon), to form the depositing liquid. As the cyanide of copper is not freely soluble in the potassium cyanide, it should be desolved to saturation. Free cyanide should be afterwards added to the extent of two ounces per gallon. This will promote rapid working, but there is also a stronger tendency to give off hydrogen at the cathode, the deposit at which may contain large quantities of gas. This solution works best at a temperature of 100 degs. Fah."—Urquhart's Electrotyping.

Nickel Solution.—The double nickel salts are generally purchased in commercial form ready for solution according to these directions: "Dissolve the compound in hot water to saturation; afterwards dilute with water. The proportions are three-quarters of a pound of salts to one gallon of water. The solution should be neutral or nearly so, that is neither acid nor alkaline. To ascertain this, test it with blue litmus paper; if the paper turns red increase the alkaline by adding ammonia sulphate. If red paper be turned blue, increase the acid by adding nickel sulphate until the mixture is as nearly as possible neutral. If there is a tendency to either side in working, it is better to have it utter alkaline."

Brass solution.—The making of a brass solution, the components of which are copper and zinc salts, given in the following formula: "Dissolve in 1,000 parts of water, 25 of copper sulphate, and 25 to 30 of sulphate of zinc; or 12½ of acetate of copper, and 12½ to 15 of fused chloride of zinc. Precipitate the mixture by means of 100 parts of carbonate of sodium dissolved in plenty of water and stir the mixture. Wash the precipitate several times by adding water to it, stirring and allowing the precipitate to subside, pouring the clear liquid away. Add to the washed precipitate a solution composed of 50 parts of bisulphide of sodium dissolved in 1,000 of water, and whilst stirring add a strong solution of ordinary cyanide of potassium until the precipitate is just all redesolved, then add three parts of free cyanide. This solution is used warm or hot. A current of about 12 volts must be employed and an anode of brass. When the deposit is white it can be attributed to too strong a current and if the deposit is red it is due to too weak a current. It is a simple matter to experiment with a small bath of solution, and a small anode and cathode, before attempting heavier work. A strong deposit of brass is a very handsome form of plating, which wears well and is not very difficult to obtain."

Slow Deposits.—The slow rate of deposit observed in plating is due to the employment of a weak current. This is frequently the case when an attempt is made to get a deposit upon a black leaded surface. In this case the resistance is naturally very great, and in consequence, very little current passes. The remedy for this is a higher pressure, the use of which in moderation, will hasten the process of deposition.

Unclean Anodes.—Absolute cleanliness is a guarantee of success in plating or electrotyping, and the reverse simply invites failure. Unclean anodes, on the surface of which dirt and oil or grease may be present, will greatly interfere with the work of plating. Some of this dirt, which is called by a philosopher, "matter in the wrong place," has been analyzed by a chemist and found to consist of particles of a great many different kinds of metals in the proportions in one particular instance of tin 33, copper 9, antimony 9, arsenic 7, silver 4, sulphur 2, and nickel 2. A certain amount of organic matter also is found present, which militates against successful plating. Thorough cleansing is the effective means of disposing of this, such as washing after a dip into an alkaline bath.

Electrotypes of Coins and Surface Pieces.—The surface is put through a preparatory process by first varnishing the back with beeswax of some rapid drying insulating solution. The face to be plated must be cleaned thoroughly and then rubbed over with turpentine in which a little beeswax has been dissolved to avoid absolute adhesion between the electrotype and original. The use of small trays is recommended, with a connecting wire attached. These depositing trays just hold a coin securely, and make perfect contact between it and the cathode.

When a dry, clean surface is first placed in the solution the liquid may not take hold, due to a minute film of air on the surface. This must be removed by wetting the coin until signs entirely disappear.

Wax Impressions.—The intaglio or impression of a coin in wax is obtained by cleaning it thoroughly, and then dusting its surface very carefully with plumbago, leaving only a delicate film. It is then placed flat upon the wax plate of composition and pressure applied in the electrotyper's press. If a good impression has been obtained, the surface is dusted over with plumbago by means of a soft camel's hair brush.

Formula for a Conducting Solution for Moulds.—To obtain a conducting surface without the use of plumbago, the following formula is recommended: "Dissolve phosphorous in pure alcohol until a strong solution is obtained and wash the mould with the mixture. A silver solution is prepared by dissolving nitrate of silver in aqueous ammonia to saturation. It is to be poured evenly over the surface of the mould, and allowed to float over it for a few minutes; the solution is poured off and the mould allowed to become partly dry, when it is again floated with the mixture. Spots that do not appear to take the solution readily must be wetted with it by means of a soft brush." A surface prepared in this manner is actually covered with a film of precipitated silver, highly conductive, and by some considered far superior to the old-established plumbago process. From what has proceeded, it may be learned that the degree of saturation of the solution, and the strength of current, are always related to each other in a manner that can only be ascertained experimentally. Thus, if a saturated solution of copper is employed, the deposit is crystalline. If the solution is diluted with from two to four times its bulk of water, the metal is deposited in a malleable state, and a still further dilution will invite deposits of a granular character. A weak solution and a strong current will cause a black, spongy coating to appear associated with hydrogen bubbles. Under conditions which remain uniform, a definite deposit per second, per minute and per hour, is assured. An ordinary electrotype takes about five hours to become thick enough for service.

Pewter Vessels.—This class of vessels are first copper-plated before undergoing the gilding or silvering process. The process of gold plating requires the use of the salts called the double cyanide of gold and potassium, and silver plating the double cyanide of silver and potassium. In plating with either of these solutions, the above mentioned precautions are necessary as regards absolute cleanliness, etc. When silver is being plated too heavy a current, which forces the deposition, will give rise to a gray and crumbling coating. Bisulphide of carbon in a minute quantity, will make the deposited silver bright if introduced into the solution. In gold plating, generally performed in the insides of silver plated utensils, the gold solution is poured into the vessel, and a gold anode suspended in the center from the positive pole of the dynamo, the negative being attached to the article itself.

CONVERSION OF A TELEPHONE EXCHANGE FROM THE MAGNETO TO THE CENTRAL BATTERY SYSTEM.*

BY B. S. COHEN.

(Concluded from page 237.)

While the exchange is under construction the outside engineering and the instrument-fitting departments will be at work.

The work to be done by the former will vary according to the existing conditions. If the subscribers' lines are already underground it will merely be necessary to divert the ducts and cables into the new premises, making the diversions in such a manner that the existing cables leading into the old exchange are teed or looped into the new cables and can be cut away from the latter when the change-over is effected.

If the system is an overhead one, and owing to wayleave difficulties it is quite impossible to put the wires underground, then the only alternative is to put as many of the open wires as possible into aerial dry-core cable.

For underground work, the modern tendency is to use cables with a large number of pairs, 306-pair cables and considerably over being quite commonly used. For conduits, glazed earthenware pipes laid in cement or cement blocks are probably the most satisfactory.

The distribution from the termination of the underground cables to the subscribers' offices is generally effected by means of open wires, and with a properly designed system the aim should be to keep the length of the open distributing wires to a minimum consistent with reasonable expenditure. With an underground system already existing, the new cables will be either looped or teed in, the method adopted depending on the distance between the old and new exchanges, and the position of the new exchange with respect to the heaviest cable routes.

Figs. 4 and 5 show arrangements of the cable generally adopted when the new exchange is quite close (within a couple of hundred yards of the existing one). In the first arrangement tee joints are made and in the second the cables are looped in. It will be seen from the drawing that the operations at the change-over are simple, it merely being necessary to disconnect the old exchange by inserting wooden plugs into the test jacks. The old leads can be cut away after the opening of the new exchange. When Fig. 5 is adopted, the old exchange can be immediately disconnected by cutting away the temporary cross-connections at the new exchange, and the old cables can be recovered without interfering with the live cables. With the teed-in system, however, the live teed joints have to be stubbed. On the other hand, the looped-in system is not so economical in cable. Further details of the change-over will be described later on. When the new exchange is some distance from the old one and is on the heaviest side of the routes, as it should be if its position is an improvement on that of the old exchange, a modification of the looping-in method must be employed.

FIG. 5.

Fig. 6 illustrates this method. The cables passing the new exchange are cut into and cables leading both in and out are brought on to the main frame. The subscribers to the right of the new exchange have thus had their lines shortened and the lengths of cable between the old and new premises will be used temporarily for maintaining the circuits through to the old exchange, and when the change-over is made are available for bringing in the circuits to the left of the new exchange. To illustrate this, two lines are shown on the drawing, viz.—Nos. 840 and 300—of which 840 is assumed to be a subscriber to the right of the new exchange and 300 is one to the left of the old exchange. The cable carrying the line in from 840 is terminated on a pair of horizontal terminals on the main frame in the new exchange and cross-connected to the pair of arresters in connection with No. 840 line inside the new exchange, and it is assumed that the line out from 840 to the old exchange will be ultimately used for bringing in No. 300 to the new exchange. This line out is terminated on another pair of terminals and cross-connected to 300 line inside the new exchange. In order to keep No. 840 working until the change-over takes place, temporary cross-connections marked A and B are run, connecting the line-in to the line-out. Now turning to the old exchange, the working test jacks and arrester in connection with lines 840 and 300 are shown and an additional test jack, C, which is a temporary arrangement, is also shown, wired to both 840 and 300. A wooden insulating plug is inserted in this test jack, and it will be seen that when the plug is withdrawn 300 and 840 will be connected together as far as the old exchange is concerned.

FIG. 6.

When the change-over takes place, the insulating plug is withdrawn at the old exchange and the temporary wires A and B, which are of a different color to the permanent wires in order that they may readily be identified, are cut away in the new exchange; 300 and 840 will then be working through to the new exchange.

The permanent connections are also shown in Fig. 6. It will be realized that great care must be taken in planning this method out. The leading-in cables from the pothead joints to the horizontal side of the main frame are generally made up of 22 S.W.G. wire, insulated with a combination of silk and cotton, and protected by a lead covering. They are made with a similar number of pairs to the cables to which they are joined, and are very compact; thus the 306-pair size is only 2 inches overall diameter.

We must now consider the work to be carried out by the instrument fitting department. As a temporary measure, in order to enable the existing instruments to work with both the old and new systems, a condenser of 2 mfd. capacity is inserted in series with the subscriber's bell, so that when the telephone is in the normal position the bell and condenser are across the loop. In most cases the condensers can be fitted in the battery boxes. No other modification is necessary in the circuits of the instruments, but as the receiver and secondary of the induction coil will close the loop during conversation, the former must be so arranged that the current from the central battery will produce a magnetic field in the same direction as that of the permanent magnet. If the receiver is connected up in such a manner that the field set up by the current from the central battery opposes that of the permanent magnet, the hearing will be faint. When the instrument fitter is inserting the condensers, he tests for this with the testing clerk at the exchange, who puts current in the proper direction on the line,

Condensers are also inserted in series with all bells or indicators in connection with switching apparatus of any description fitted at the subscribers' offices. The instruments are now capable of working on both the old and new systems, and after the change-over has taken place they can be replaced by new central battery instruments. The methods of working a number of extension and exchange lines on the central battery system at a subscriber's office are many and varied, in order to give the facilities for secrecy and intercommunication which are demanded in this country. Special bells are run from the central exchange to the subscribers' branch switchboards, to supply the power necessary for both speaking and signaling between the extensions, private lines, etc.

Whilst the conversion of the system is in progress, the lines are repeatedly tested from the new exchange as they are connected up to the main frame. With the voltmeter method of testing adopted, this work is carried out with ease and rapidity, and the test clerk can in a few seconds determine the insulation and copper resistance of any line.

A maximum copper and minimum insulation resistance is fixed for both subscribers' and junction lines, and the exchange relays are adjusted in order to operate through the maximum copper resistance with a sufficient factor of safety and to release with a resistance well below the minimum insulation resistance. When adjusting the relays, the maximum working current is also passed through them in order to allow for the effects of residual magnetism. The traffic department has to furnish lists showing how the subscribers' and junction lines are to be distributed on the switchboard. This is obtained from the records of calls per individual subscriber and calls per operator's position in the old exchange. A curve should be plotted showing the calls per operator's position per busiest hour, and an average line drawn with maximum and minimum lines at 10 per cent. above and below this respectively.

The exchange instrument modifications and outside system having been completed, the change-over can take place immediately after a complete test of the whole system has been carried out.

Owing to the large number and complex nature of the circuits, and the amount of apparatus, considerable time must be allowed for the final testing in a large exchange.

First comes the testing of the multiple jacks. In the new London Wall Exchange of the National Company, which has just been opened, there are a total of 681,550 jacks connected with the subscribers and outgoing junctions; each of these jacks is provided with three connections, the two lines and the engaged test, and each jack must be tested for disconnection, reversal of the three wires on the one jack or transposition with the wires on another jack, and for contact. Test boxes are generally provided for this purpose fitted with plugs and cords which can be inserted in the corresponding jacks at any part of the multiple, and relays and lamps so arranged that reversals, contacts, etc., will be indicated by lamps glowing. In order to obviate the liability to personal error in this test, and to increase the speed of test, an automatic arrangement provided with a form of Morse inker has been used.

The testing of the various circuits and

the relays in conjunction with them is carried out by means of test sets equipped with relays, lamps and resistance coils arranged to allow the maximum and minimum currents to flow through the circuits under test.

The tests of the charging and ringing machines, besides including the usual tests for efficiency, temperature-rise, etc., include a test for disturbances set up by the commutation, the charging machines having to take a varying exchange load direct without the cells in circuit and without the introduction of any serious disturbances on the lines.

The internal resistance of the battery is also taken and a test for cross talk made. Besides these tests, a proportion of the deliveries of all apparatus, such as plugs and jacks, relays, heat coils, fuses, lamps and keys are tested, both mechanically and electrically, in the test rooms at the headquarters of the telephone company to whom the exchange belongs and the remainder of the apparatus examined and passed by the clerk of the works, who is stationed at the exchange which is under construction, before it is allowed to be fitted up.

When all the faults discovered during the testing are rectified, a certificate of completion can be signed by the engineers responsible for the various branches of the work.

The change-over can now take place. This is usually carried out at the week end. To consider an actual case, it is assumed that the looping-in system has been adopted (see Fig. 6), and that the time for changing over, say 4 o'clock Saturday afternoon, has arrived.

Men are stationed at the old exchange test board by the temporary jacks c in order to pull out the wooden pegs, and others at the ordinary test jacks with a supply of wooden pegs to insert in them and thus disconnect the old exchange.

At the new exchange arrangement has been made to cut off the temporary cross-connections, and the heat coils have already been inserted in the arresters (these completing the connection between the inside and outside lines). Previous to this, however, the covers have been removed from the working line and cut-off relays and slips of thin insulating material inserted between the contacts of the cut-off relays. By this means the line apparatus is kept disconnected from the lines until the first insertion of the plugs into the jacks, when the actuation of the cut-off relays releases the insulating slips, which fall to the floor.

All the operators are in attendance, the majority at their positions in the new exchange, only sufficient being left at the old exchange to take the normal Saturday afternoon load, which is generally small. The operators in attendance at the new exchange will not find their surrounding entirely novel, as they have spent some time, in detachments of two or three, at the new board, familiarizing themselves with the multiple and the location of the various junction lines, order wire keys, etc., under the guidance of a senior operator or instructress from an operating school, if such exists. The actual change-over takes a surprisingly short time, even in a large exchange.

It is customary to provide the operators attending at the new exchange with lists of numbers which can generally be obtained during the slack time, such as hospitals, fire and police stations, and other public institutions, also doctors. These lines can be tried directly the change-over takes place, and the remaining lines on the first normal day.

Neutralizing Static Electricity.

At a meeting of the New England Cotton Manufacturers' Association, held in Boston April 26, a paper upon the above subject was presented by Philip Dana, of Westbrook, Maine. The writer stated that most mill men familiar with the manufacture of cotton, have been troubled by static charges on cold, dry mornings, either with a card or drawing frame, and that it has been greatly desired to overcome it completely. It has been found necessary to keep a fairly high degree of temperature and humidity in the rooms, partly to obtain more uniform and stronger work, and partly to overcome this static electricity. The use of moist steam is unhealthy, and a separate power plant for running humidifiers before the machinery is started up is not feasible.

The warps become thoroughly charged in passing through the rolls and cling to the trumpets, becoming greatly snarled and cutting down production on winders and beamers. Mr. Dana said that he had applied the Chapman process of removing static electricity to his unwinding machines with entire success, and that he anticipated using it next winter on drawing frames, especially where long stapled cottons are used, both carded and combed.

The device consists of a source of alternating current, such as any 110 or 220 volt a. c. lighting system, a transformer to raise the alternating current voltage from this potential to 10,000 to 20,000 volts, and an inductor to distribute this high voltage influence over the substance to be treated. The inductor consists of fine steel wires incased in hard rubber, the steel points being flush with the rubber case. The apparatus operates on the principle that a static charge spontaneously selects from a neighboring alternating charge the kind and quantity of charge sufficient to neutralize itself. As static electricity in any material is usually very small in quantity, although of very high voltage, the transformer may be constructed so as to limit the maximum output to a few milliamperes, thus making it perfectly safe for the operatives even if a person should take the whole charge. The process has also been successfully used in paper machines, printing presses, paper bag machines and woolen mills.

The International Railway Congress.

When the International Railway Congress opens in the city of Washington to-morrow the United States will, for the first time, entertain the eminent railroad men of the world in one of their quinquennial gatherings. Five years ago they met at Paris; ten years ago at London; fifteen years ago at St. Petersburg. There will be offered in conjunction with the formal meetings of the congress an ocular demonstration of all that is wonderful in American railroad science. For this undertaking, the manufacturers of railroad goods have clubbed together and made a small world's fair near the Washington monument. Congress granted them permission to use public ground for the purpose of the exhibition.

Mr. J. Alexander Brown, who is running this adjunct to the congress, says that neither the world's fair at Paris, the Chicago fair of 1893 nor the St. Louis Exposition last year had such displays of modern railroad machinery as this week's show will contain. There will be no "Dewitt Clinton" locomotives or other antiques, but the latest wrinkles in railroading will be plentiful. The manufacturers say the exposition will represent an outlay of over a million dollars, while the space occupied by exhibits will be greater than that devoted to similar displays at any of the world's fairs.

The General Railway Signal Company, which makes block signals and other devices, is spending $20,000 in setting up a life-sized locking station.

One of the interesting exhibits will be a battery of 60 sets of airbrakes, ranged side by side, so that the way they would work from end to end of a long train may be seen at a glance.

Electric locomotives for use in tunnels and mines are also among the exhibits.

Owing to the temporary character of the exhibit, and the fact that the parking cannot be cut up with ballasted tracks, no locomotives will be seen on the exposition grounds, but in the Pennsylvania yards, a half mile distant, 1,800 feet of trackage has been set aside for locomotives and cars. There, the principal locomotive companies and car building concerns of the country will show their wares under practical conditions.

The American Electrochemical Society's Boston Meeting.

The seventh general meeting of the American Electrochemical Society was held last week in Boston. Nearly 100 members were present.

A large number of papers were presented and those principally discussed were on the subjects of "Reversible and Irreversible Electrolytic Polarization," "The Aluminum Electrolytic Condenser," "Economic Temperature for Copper Refining," "Electrolytic Conduction," "Absoute Potentials," etc.

The newly-invented cell for the production of caustic soda and chlorine was described by the inventor, Mr. C. P. Townsend.

There were several exhibits of electrochemical apparatus and electric furnaces.

Consolidated Electric Smelting Company Organized.

The organization of the Consolidated Electric Smelting Company of Sault Ste. Marie is announced from Calumet, Mich. This new company will take over the interests of the Hatch Electric Smelting & Refining Company, combining the interests of both the old American and the old Canadian organizations. The new company has elected the following officers: George P. McCallum, president; F. C. Bowman, of Duluth, vice-president; A. E. Marriott, secretary; Cyrus W. Baldwin, treasurer.

The initial operations of the company will be directed toward handling zinc ores.

Iowa Electrical Association's Officers.

At the recent convention of the Iowa Electrical Association held in Dubuque the following officers were elected for the ensuing year: President, Austin Burt, Waterloo; vice-president, A. W. Zahm, Mason City; secretary, P. E. Bellamy, Knoxville, and treasurer, N. A. Maul, Belle Plaine.

Dixon Crucible Meeting.

At the annual meeting of the stockholders of the Joseph Dixon Crucible Company the old board consisting of Edward F. C. Young, John A. Walker, Edward L. Young, William Murray, George T. Smith, Joseph D. Bedle and George E. Long, was unanimously re-elected. The board of directors re-elected the former officers, namely, Edward F. C. Young, president; John A. Walker, vice-president and treasurer; George E. Long, secretary. Judge Joseph D. Bedle was also re-elected as counsel.

The stockholders present expressed themselves as thoroughly satisfied with the management of the company by its officers.

Of the total number, 7,345 shares, there were represented 7,145 shares.

PERSONAL MENTION.

MR. JOHN I. BEGGS of the North American Company has been elected president of the United Railways Company of St. Louis, succeeding Mr. Murray Carleton.

MR. J. M. BRAMLETTE, general superintendent of the East St. Louis (Ill.) & Suburban Electric Railways, has accepted the position of general manager of the Philadelphia & Western Interurban Electric Railway.

Inquiry for a Motor Generator.

Electricity Newspaper Company :

I am in need of a motor generator of about 13 to 15 kw. to be used at the coming dental convention of the New Jersey State Dental Society at Asbury Park this summer. I desire to run from the street electric car current wires 500 volts and reduce the same so that 110 volts direct current can be used in the building for running motors, dental furnaces, etc. If you have knowledge of any such generator will you kindly communicate with me and oblige Yours very truly,

Harvey Iredell.

New Brunswick, N. J., April 26, 1905.

Revolving Field Alternators and Rotary Converters.

The revolving field alternator for medium and large size machines, is now the standard type, and has been adopted by practically all American and European manufacturers. Bulletin No. 56, just issued by the Electric Machinery Company, Minneapolis, Minn., illustrates and describes in detail the revolving field generators and rotary converters, manufactured by this well-known concern.

In the revolving field machines, the base, bearings and armature are of massive construction to insure stiffness. The frame is of sufficient length to permit the armature being moved parallel to the shaft to give access to the fields and armature.

The bearings are strongly constructed, each one having two oil rings, and carefully cut oil grooves to insure perfect lubrication and cool running under heavy overloads.

The pole pieces have laminated tips and are provided with air ducts communicating with the inside of the field ring. The field air ducts index with the armature ducts so that good ventilation is easily obtained with little waste of power.

The rotary converters are built on lines similar to the direct current apparatus turned out by the above concern. Solid pole-pieces, extra heavy shafts and a rigid commutator are characteristics of these machines.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED APRIL 25, 1905.

Electric Railways and Appliances.

788,280. Electric Railway. Leon W. Pullen, Philadelphia, Pa., assignor to the Wireless Railway Company. Filed July 18, 1904.

788,290 Protected Third-Rail System. Isaac C. Thorne, Glen Cove, N. Y. Filed Jan. 2, 1904.

Electric Lights and Appliances.

788,477. Aerial Telegraphy. James F. King, New York City. Filed June 23, 1903.

THE TELEPHONE WORLD.

Reduction in Rates.

The New England Telephone Company has made some substantial reductions in its rates for certain classes of service in the Boston, Mass., Metropolitan and suburban exchanges. The new rates took effect May 1. These reductions have been made according to the policy recently inaugurated of reducing the rates so far as the operating expenses would permit.

For the suburban measured service, exchange rates allowing communication only between subscribers to the suburban exchanges on special circuit have been cut from 4 to 3 cents for additional calls, the rate for 600 calls, $48, remaining the same. On the two-party circuit the rate also remains the same, with a cut from 4 to 3 cents for additional calls.

On the unlimited suburban exchange, rates for residence stations for the special line have been cut from $66 to $54. On the two-party circuit from $51 to $42, while for four parties on one circuit there will be a new rate of $30. It is thought that these reductions will benefit a large number of the company's patrons and will enhance the value of the exchanges.

A number of citizens of Glasgow, Ky., met recently for the purpose of talking over the advisability of organizing a telephone system at that place. Something like $4,000 has already been subscribed to the fund, and the promoters claim that they will have no trouble in interesting enough money to put the enterprise through. The system in Glasgow is owned by the Gainesboro Telephone Company of Sparta, Tenn. The one to be established will be operated by the Home people.

News from Middletown, N. Y., states that the annual election of the Warwick Valley Telephone Company was held recently. W. A. Hynard, W. E. Bailey and F. M. Cummins were unanimously re-elected directors. The report of the treasurer showed the finances to be in excellent condition. It was voted that no dividend should be paid until the debts of the company are discharged.

The property, franchise and all appurtenances of the United States Telegraph & Telephone Company, with exchanges in 14 counties in Iowa, were sold last month to Thomas Cascaden, of Waterloo, for $55,000 at a public sale on order of the Federal Court.

The Grand Blanc, Mich., Telephone Company, an Independent organization, has been incorporated by Grand Blanc farmers and the following officers were elected: A. D. Banker, president; Dr. Parker, secretary; Cranston Clark, treasurer. About 50 farm residences will be connected on the start.

The Union Telephone Company of Trump, Md., of which Mr Charles L. Almony is president, and Mr. S. S. Van Trump manager, has increased its capital from $3,000. to $10,000, and will extend its lines.

The Van Dermark Telephone Company has been organized at Scio, N. Y., with a capital of $1,200. The company will build a line from Van Dermark Creek to Scio, there to connect with the Inter-Ocean Telephone Company's line.

Independent Telephone Movement in New York State.

A mortgage has been filed in the county clerk's office at Rochester by the Independent Union Company for $500,000, given to the Knickerbocker Trust Company to secure bonds for the same amount. The purpose of the company is to acquire and operate telephone lines and exchanges in Erie, Niagara, Chautauqua and Orleans Counties. The promoters of the Independent Union Company, in the Rochester Telephone Company and in the Independent Telephone Securities Company, whose home is in Utica, are in many cases the same and the expansion of the Independents gives promise that the Rochester company will ultimately be taken over.

The Independent Telephone Securities Company at present controls about 1,000 miles of telephone wires and 250 stations in Oneida, Lewis, Herkimer, Jefferson, Oswego and Otsego Counties. This is the result of the plan to establish a system by acquiring central of companies wherever it can do so on satisfactory terms, and this plan has led up to the important action now being considered.

The latter company recently executed a mortgage to the Security Trust Company of Rochester for $15,000,000 to secure a bond issue of equal amount, the proceeds of which will be used in acquiring companies. As fast as the Independent companies signify a desire to join the new company and participate in the long-distance service, they will be taken in and the bond issue authorized will be used to complete the financial arrangements. The whole amount of $15,000,000 in bonds will not be issued at once, but in amounts required to take in the companies as they are ready.

The Standard Manufacturing Company, makers of speaking-tubes and private-line telephones, will shortly move from Meriden to Bridgeport, Conn. Considerable Bridgeport capital has now been invested in the enterprise.

The proposed increase in the telephone rates has been discussed quite freely in Ilion, N. Y., and several of the business men and others have already taken steps to form a local stock company and operate an exchange in the village. The trustees will be asked to grant a franchise.

A new exchange of the Auburn Telephone Company, was opened lately in Watertown, N. Y., and over 2,000 residents called and inspected the building. There are at present over 1,400 connections from the Auburn office.

Articles of incorporation for the Orange Home Telephone & Telegraph Company, and for a similar organization at Anaheim, Cal., have been filed with the county clerk. The companies are branches of the Home telephone system and will be centers for connection with the existing lines in Orange County.

Plans have been filed for the enlargement of the three-story telephone exchange of the New York Telephone Company, at No. 424 West 58th street. The cost of the improvement is estimated at $125,000.

The Warrington, Pa., Mutual Telephone Company has made arangements to extend its line from Warrington to North Wales via Chalfont. This will give it an outlet through the Keystone Company, where connection can be made for long distance calls. A large percentage of the farmers about Warrington, Tradesville and Chalfont have telephones in their houses. A number of prominent people in North Wales are interested in the movement. This will be a great convenience to the farmers, as the expense of building and maintaining this line is nominal.

A director of the Pittsburg & Allegheny, Pa., Telephone Company is quoted as saying that during the months of March and April of this year, the company put in more private exchanges than during any similar period in the company's history. The business is said to be growing nicely. Although the company's common and preferred stock have been listed on the local exchange for more than two months, no sales of either issue have ever been posted. The common quotes at 15 bid, and the prferred at 60 bid.

The annual meeting of the Bloomer, Wis., Telephone Company was held last month. The officers elected for the year were: President, Henry Lebeis; vice-president, P. A. Peterson; secretary, E. R. Parker; treasurer, W. E. Kitch. The directors will declare a 12 per cent. dividend.

The Colorado–Wyoming Telephone Company lately filed its articles of incorporation in the office of the Secretary of State at Denver. The company is a Wyoming corporation, and conducts a telephone system in northern Colorado and southern Wyoming. The filing was made in connection with the appointment of T. C. Williams, of Greeley, as the agent.

Joseph Studebaker has secured a franchise for a telephone system in Flora, Ind., and will receive bids for the installation of an exchange, poles, wires, etc.

The Central Union Telephone Company contemplates placing its wires underground in Youngstown, O.

The Sunset Telephone & Telegraph Company proposes a subway system for its wires in Tacoma, Wash.

A telephone franchise has been granted to Ed. J. Vaughn and others by the Jerseyville, Ill., city council.

The Byron, N. Y., Telephone Company's business has grown so far beyond all expectations that a new switchboard has had to be installed.

Telephone Incorporations.

The Southern Cayuga Telephone Company, Poplar Ridge, N. Y. Capital stock, $15,000. Incorporators: Isaac P. Hazard, Charles Pyle and Isaac P. Hazard, Jr.

The Badger Telephone Company, Oconomowoc, Wis. Capital stock, $2,000. Incorporators: Thomas Steele, John J.. Reid and Henry E. Rosnon.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Albion, Mich.—The council has granted a 30-year franchise to the Albion Electric Light Company.

Ashland, Va.—It is reported that the Virginia Passenger & Power Company has received the contract for lighting this town with electricity.

Bryan, Tex.—The building and operating of an electric light plant here is considered favorably by the committee of aldermen, who were appointed to look into the matter.

Canton, N. Y.—The amount of $10,000 is to be expended in improvements by the electric light company of this place.

Clarinda, Ia.—Plans are being prepared for the erection of the new building of the Lee electric light plant.

Conrad, Ia.—This city is to have an electric light plant soon.

Dubuque, Ia—The city council is discussing the question of putting in incandescent electric lights in the alleys of the business part of this city.

East St. Louis, Ill.—The city council has granted to the St. Clair Light & Power Company, of this city, a franchise to erect an electric light plant to cost $50,000.

Ione, Ore.—It has been decided to issue bonds to cover the cost of a municipal electric lighting plant, which will be installad immediately.

Kennewick, Wash.—E. Wood, of Genesee, offers to put in an electric light system and a flour mill here at once, if he can secure a franchise for the electric light system.

Maytown, Pa.—This village has contracted to have its streets illuminated by electric lights.

Monroe, Ga.—The citizens recently voted to issue bonds for an electric light plant.

Monticello, Fla.—The Monticello Power Company has been incorporated with a capital of $10,000 to operate an electric light and power plant.

Oxford, N. S.—The electric light plant and many business places were totally destroyed by a recent fire.

Pawnee, Ill.—Arthur Carswell has purchased the electric light plant from Alvin Underwood.

Sterling, Col.—The Sterling electric light plant, owned by O. P. Sells, of Grand Island, Neb., was totally destroyed by fire. The loss is estimated at $18,000.

St. Augustine, Fla.—At a recent meeting of the city council a communication was received and read from Gen. J. C. R. Foster, submitting a proposition to install an electric lighting, heat and power plant in this city.

STREET RAILWAYS.

Ann Arbor, Mich.—A franchise has been granted to the Adrian & Ann Arbor Electric Railroad Company by the city council. This is the last franchise necessary, and the construction of the line will be begun at once.

Atchison, Kan.—Brown and Doniphan County people are talking of the proposed electric line to run out of this city, with the purpose of reaching the best towns in both counties.

Bloomington, Ill.—The Bloomington, Decatur & Champaign Interurban Company has bought the Consumers' Electric Light & Heating plant of this city for $130,000. The plant will be used to supply power for the chain of interurban lines throughout central Illinois.

Carrollton, Ky.—The Shelbyville & Ohio River Electric Railway Company, which has been incorporated at Eminence, is going to build an electric railway from Shelbyville to this city, a distance of 42 miles. Luther H. Leber, of New York, civil engineer, has been surveying the route through Carroll County.

Clarksville, Tenn.—The Clarksville Street Railway Company has purchased the plant of the Queen City Electric Light & Power Company; extensive improvements will be made.

Cleveland, O.—The Cincinnati, Dayton & Toledo Traction Company has increased its capital from $5,000,000 to $5,250,000.

Des Moines, Ia.—The Rock Island road is seriously considering the use of electricity on portions of its lines out of this city, and officers of the company have gone over the lines, where it is proposed to do this work, with electrical engineers. These engineers have been supplied with plans of the road, profiles, etc., and are now engaged in drafting plans and preparing estimates for the work.

Elmira, N. Y.—An electric line is soon to be erected between this city and Waverly.

Evansville, Ind.—The Evansville & Mount Vernon Electric Railway Company, capitalized at $10,000, has filed articles of incorporation to build an electric line between here and Mount Vernon. Fred P. Leonard, William N. Ford and others are interested.

Guadalajara, Mex.—M. C. Miller, of this city, is making good progress in his project for building an electric railway from this city to the port of Chamila, on the Pacific coast of Mexico.

Indianapolis, Ind.—The Indianapolis & Chicago Air Line Traction Company has been incorporated under the laws of the State of Indiana and will build and operate an electric line between this city and Chicago.

Kalamazoo, Mich.—Eastern capital proposes building a trolley line from here to Niles, 70 miles long, the missing link that will connect Chicago and Cleveland, and which will be, when completed, the greatest electric line in the world. The entire line will be 500 miles long.

Kenton, O.—The Sandusky & Southwestern Traction Company of Ohio has been reorganized, and is getting ready to complete the line from Wapakoneta to this place. For further information address F. H. Blodgett, Wheeling, W. Va., contractor for said company.

La Crosse, Wis.—The La Crosse Street railway Company will extend its electric line from Onalaska to Holmen, a distance of about 10 miles.

Middletown, N, Y.—The Wallkill Transit Company has recently been organized here and incorporated with an authorized capital of $350,000, as a successor of the Midletown-Goshen Electric Railway Company.

Monroe, Mich.—The talk of an electric line from this city to Dundee, 17 miles, is assuming definite shape. The village of Maybee will be on the line, and it will also tap the vast glass sand deposits west of this city.

Oconomowoc, Wis.—The Milwaukee Light, Heat & Traction Company has been granted a franchise to build an electric railway from Waukesha Beach to this city.

Platteville, Wis.—A party of men from Fargo, N. D., are behind a plan to build a trolley line from Galena to this place. The object is to reach several mines which are being developed.

Sandusky, O.—D. D. Washburn, of Greenwich, has filed an application with the county commissioners for a franchise for an electric line through the village of Greenwich and on other public highways in the county.

Shelbyville, Tenn.—It has been announced that all the money necessary to build and equip the proposed electric railway from here to Fayetteville, and thence to connect with the Southern road at Huntsville, has been raised, and that the line will certainly be built.

Stratford, Ont.—A company has been incorporated to build an electric railway from here to Great Bend and Lake Huron.

Walnut Creek, Cal.—An electric road will be built to connect this city with Oakland, Danville and Concord.

Washington, D. C.—Acting on the advice of Attorney General Moody, Secretary Taft has granted permission to a street railway company to construct an electric line over the Government bridge across the Mississippi at Rock Island.

POWER PLANTS.

Chicago, Ill.—The Chicago Southern Traction Company has purchased a site in Riverside, for the construction of a new power plant, to cost $100,000.

Dover, Del.—The Citizens' Light, Heat & Power Company, with a capital of $300,000, has been incorporated to erect plants for generating electricity.

Holyoke, Mass.—A water power plant, to cost $150,000, is to be erected here according to plans made public by Treasurer R. C. Winchester, of the Holyoke Water Power Company. Charles E. Gross, of Hartford, Conn., is president of the company, and much of the stock is held in that city.

Providence, R. I.—Plans are being prepared by Architect Richard P. Jenks, Banigan Building, this city, for the erection of a new power plant for lighting purposes.

BIDS WANTED.

Bristol, Va.—Cash bids for a franchise to operate electric light and power plants here, will be received by President J. W. Mort until noon May 10.

Fort Sheridan, Ill.—Sealed proposals in triplicate will be received until May 10 at the office of the constructing quartermaster here, for furnishing and installing electric light fixtures and wattmeters in 14 buildings. William Weigel, Captain-Quartermaster.

Washington, D. C.—On May 23 the Bureau of Supplies and Accounts will open bids for furnishing the Mare Island, Cal., and Puget Sound, Wash., Navy Yards with the following: Schedule 204, motors, incandescent lamps, telephone cord, etc., battery cells and carbons. Blank proposals can be obtained at the Navy Pay Offices in San Francisco and Seattle, or of the Bureau.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 15@15⅛c.; Lake 15⅛@15¼c.; casting, 14¾@14⅞c.

The net earnings of the Electric Company of America for the past year were $408,901.

Stockholders of the Interborough Railway Company of New York hold their annual meeting May 10.

General Electric declined 10 points and Westinghouse 4 points in last week's dealings on the New York Stock Exchange.

New corporations formed in the Eastern States during April with a capital of $1,000,000 or more had a capitalization of $180,000,000.

It is said that the United Metals Selling Company will reduce its copper prices another ⅛ cent per pound to-day, making its official prices 15 cents for Lake, 14⅞ for electrolytic and 14⅝ for casting.

Charles D. Barney & Co., of Philadelphia, has purchased $1,750,000 of Lake Shore Electric bonds above 90. These bonds were taken up by a syndicate of Cleveland, O., banks at the time of the Everett-Moore troubles.

The Stanley Electric Manufacturing Company, with office in Jersey City and works at Pittsfield, Mass., filed an amendment of certificate with the Secretary of State of New Jersey reducing its capital stock from $4,000,000 to $2,300,000.

The Shawinigan Water & Power Company of Montreal, Canada, has just disposed of $4,000,000 of its first mortgage 5 per cent. bonds of an authorized issue of $5,000,000. New York and Boston capital is largely interested in the company.

The National Carbon Company has declared the regular quarterly dividend of 1¾ per cent. on its preferred stock, payable May 15. Books close May 5 and reopen May 16. The board took no action on the common dividend, which, if the payment of a semi-annual disbursement is to be maintained, is not due until July 1.

Announcement has been made in Detroit of the sale of the Jackson & Battle Creek Company's third rail electric line by C. M. Spitzer, of Toledo, to a syndicate of Michigan men—Myron W. Mills and George G. Moore, of Port Huron, and James R. Elliott, of Lansing. The line is 48 miles long and two years ago cost $1,500,000.

The transfer books of the Havana Electric Railway Company will be closed from May 20 to May 25. Stockholders of record May 20 will have the right to subscribe for bonds and stock of the Havana Central Railroad. This company has been organized to construct about 120 miles of electric railroad radiating from the city of Havana, Cuba.

A certificate of increase of capital stock of the Interborough Railway Company of New York was recently filed. The certificate states that the capital stock is increased from $400,000 to $5,000,000. The stockholders who signed are Alfred Skitt, Cornelius Vanderbilt, Andrew Freedman, G. W. Young, John H. Schofield, Arthur Turnbull, William J. Fransiola and Walter Luttgen.

The Fitchburg & Leominster and Leominster, Shirley & Ayer (Mass.) Street Railway Companies, which were authorized Friday last to consolidate, will form the nucleus of a new air line electric system between Fitchburg and Boston. The new company, which proposes to operate between these two centers, will be capitalized for $1,500,000 and the construction of 27¾ miles of double track from Ayer to Cambridge, the eastern terminus of the line will, it is estimated, cost $2,000,000.

EDITORIAL NOTES.

The Electric Lighting Situation.

Last week several bills bearing on the price of electric current in Greater New York were passed by the Legislature. One provides for $90 a year arc lights for Brooklyn, another reduces the price of electric current for private consumers to ten cents a kilowatt hour in Manhattan and to twelve cents in Brooklyn.

A commission of three will be appointed by the Governor for a term of years to see that the law is carried out and to supervise things in general.

The schedule of rates for electric current, which has been in force in this city for several years, is fifteen cents per kilowatt hour for the first two hours of use. For the third and fourth hours the charge has been ten cents per kilowatt hour, for the fifth and sixth, seven and one-half cents, and over six hours, five cents.

These figures do not seem exorbitant when it is borne in mind that a large amount of good machinery and apparatus has to be thrown in the scrap heap frequently after but a few years' use, in order to keep step with the onward march of progress.

The action of the politicians at Albany would certainly seem drastic and leaves the electric lighting companies throughout the State at the mercy of a commission with sweeping powers. This commission has greater authority to enforce its orders than any other commission ever created in New York.

Upon the complaint of any city, town or village authorities or of one hundred customers of a gas or electric company, the commission is directed to investigate the affairs of the company. After a hearing has been given, the commission, "within the limits prescribed by the law, may fix the maximum price of gas or electricity which shall be charged by such corporation or person in such municipality, or may order such improvement in the manufacture or supply of such gas, or in the manufacture, transmission or supply of such electricity, or in the methods employed by such person or corporation as will, in its judgment, improve the service."

The price set by the commission shall remain the maximum price for three years. Either the corporation or the complainants may appeal from the decision of the commission to the Appellate Division of the Supreme Court, which may modify the order.

There are to be three commissioners, at $8,000 a year, for six year terms, and with power to appoint experts and inspectors.

The commission will "have the general supervision of all persons and corporations having authority under any general or special law to lay down or erect and maintain wires, pipes and other fixtures in, over or under the streets, highways and public places of any municipality in this State for the purpose of furnishing gas or of furnishing or transmitting electricity for light, heat or power."

It may investigate the quality of gas and the methods of gas and electric light and power companies and order such improvements as may "best promote public interests."

Full power to examine plants, books and witnesses under oath is conferred on the commission.

General control is given to the commission over all State and municipal officers whose duty it is to inspect meters.

No company can get a new franchise nor can any city construct a municipal plant without the consent of the commission. Unless the commission gives its consent no company can issue new stock or bonds and no franchise or right can be transferred from one company to another unless the commission affirms.

This arrangement is delightful from a political standpoint. It creates three new places at $8,000 a year each for faithful followers to say nothing of numerous minor berths for smaller fry.

And the people are willing to foot the bills and stand for it to save a few cents each month on the electric current they may use. It looks very much like robbing Peter, not to pay Paul, but a certain set of politicians.

* * *

Co-operation in Science. The science of radio-active metals on the one hand, and the science of surgery on the other hand, represent a co-operative force seriously entertained as a means of destroying to extinction the frequently fatal bacilli of cancer.

At a great and distinguished gathering in Germany of surgeons and physicians of note, the question brought up for discussion was the relative merits of the knife versus the bloodless effectiveness of radium-coated tubes inserted in the diseased tissue. The principle upon which such possibilities as the latter rest, is the influence of short and rapid ether waves or light on death-dealing germs.

It must be understood that conservatism is the watchword in medicine. Innovations are regarded with distrust, particularly when they belong to a field foreign to the physician's experience. For this reason the work of Finsen required the backing of the most powerful of influences, no less than that of royalty itself, to reach a position in the eyes of the world that meant continued respect and appreciation. Light waves are exclusively employed for healing diseased flesh in this hospital addendum of Finsen's. The dignity and authority now possessed by the disciples of this creed are based upon the positiveness of many cures accomplished by the Finsen method. What is the basic principle of this or any other proposed cure to be carried out on these lines? What limit may be set to the possibilities involved in the broadest application of this new and fundamental idea?

The answer can best be found in the presumption of a variety of competent practitioners regarding the present drift of the problem. Curing by light means simply the limitation or elimination of germ cultures by exposure to light. Why this characteristic is peculiar to such infinitesimal micro-organisms has not as yet been answered. It is very likely that the effect of light upon the body of a microscopic life form is to produce a direct chemical change. The blind worm, sensitive to the light, can only exhibit a consciousness of this phenomenon, whether automatic or otherwise, through the influence of a chemical change caused by the light upon it. The lower forms of life are also proportionately affected, until as they descend to that ground base, the very bottom of the pyramid of life, a flood of light upon such delicate sparks of life as these means destruction. Thus, the foundation upon which anticipations rest, is fundamental with respect to germ life. But the great question which, as has been seen, is the one constantly recurring is of twofold form: first, what kind of light to use; second, how best to introduce it. It must be fully realized from this that what is called light is not necessarily visible to the human eye. Ether waves is perhaps a better, because a more general, expression to use with respect to such phenomena. They are as varied in character as those of any other medium, but unlike them, produce a gamut of effects unequalled in the whole range of physical science.

Our interest as human beings is peculiarly centered around the possibilities of light as a distinctly curative agent. It can hardly be believed that the natural condition of the body is other than that of perfect health. Medical science aided by the bacteriologist points to lapses as caused by germ life. If only these conditions are considered, which leave out accidental injuries of a vital nature, the possibilities of radium or light cures are enormous. The successful issue of such experiments lies with the bacteriologist and the electrician. Co-operation in science is the only means of searching for this panacea, and we are glad to see the seriousness with which common interests are united in the tests of its efficacy. No greater triumph could be yielded by this age than one which means restoration to health of thousands doomed by a malignant and fatal disease to read the blackest page in life. Radium, it must be understood, may not possess the qualifications to finally solve the problem of cancer cure; but at least this will remain, a principle of science on which such cures depend; and on this basis alone co-operative effort may ultimately attain the noble end for which it seeks.

Mayor Dunne, of Chicago, says he will not pay more than $50,000,000 for the railway systems of that city. In his campaign speeches, he placed the figure at which he thought the properties could be acquired at $77,000,000. He bases his last estimate on reports made by experts.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

Copper producers hold prices of both electrolytic and Lake copper firm at 15 cents, but second hands are shading the price of electrolytic to 14⅞ cents.

Notwithstanding the opening of the New York Subway, the Metropolitan Street Railway Company's earnings for April were only $10,000 less in gross returns than in April, 1904, such has been the development of traffic in New York City.

Both Houses of the Illinois Legislature have passed bills giving the city of Chicago power to sell to private consumers for heating purposes surplus electricity from municipal electric lighting plants.

The National Electrical Contractors' Association will hold its convention and exhibit in Boston, July 15-22. For this purpose the entire Mechanics' Building, containing 83,000 square feet of exhibit floor space, has been engaged.

It is announced that a consolidation has been effected by the Stanley Electric Manufacturing Company of Pittsfield, Mass., and the General Incandescent Arc Light Company of New York, under the name of the Stanley-General Incandescent Electric Manufacturing Company. The works and general offices will be at Pittsfield. The Stanley Company is controlled by the General Electric Company.

Cornell University's list of candidates for degrees in June shows 205 mechanical engineers (including electrical engineers), and eight masters of mechanical engineering in Sibley College.

A cable dispatch from Brussels, Belgium, states that a deal has been consummated in that city by which all of the lighting companies of Rio de Janeiro, Brazil, have been acquired by the Rio de Janeiro Light, Power & Tramway Company, a large American Corporation having $50,000,000 capital. Some time ago the street railway lines were acquired, so that the company now has a monopoly of the light, heat, power and street railway business in the Brazilian capital.

MAINTENANCE OF METERS.*

BY W. J. MOWBRAY.

To the company supplying electric energy which is measured by meters and charged for accordingly, the maintenance of meter accuracy is of supreme importance. Losses in other apparatus become insignificant when compared with the loss of revenue from meters that are allowed to follow their natural tendency to run slow. For example, in a steam boiler a drop of 10 per cent. from normal efficiency would be detrimental to approximately the same percentage in the single item of the cost of coal, whereas in the metering system it would be 10 per cent. of the entire gross revenue to which the supplying company is legitimately entitled. Furthermore, if a metering system did actually deteriorate so as to record 10 per cent. less than the true energy, this loss would by no means remain constant; it would continue to increase.

Periodic overhauling is the obvious and generally adopted means of maintaining meter accuracy. Overhauling—a strict examination for correction and repairs—is efficient in proportion to the cheapness and accuracy with which it is done and to the permanence of the result. Means of making the result as permanent as possible will be considered later. Attention will first be called to a portable test meter used by the writer for the accurate and almost instantaneous determination of the percentage by which a meter is running fast or slow.

This meter is similar to a customer's ordinary watt-hour motor-meter in that it has a rotating armature, each revolution of which represents the passage through the meter of a certain number of watt hours. A rotating armature in a test-meter is advantageous in that its revolutions and those of the meter under test are directly comparable, making it immediately apparent whether the latter runs faster or slower than it should. Another advantage is that the comparison of revolutions is quite unaffected by fluctuations in pressure or current which would tend to render an indicating ininstrument unreadable because of the swinging of the needle.

The ampere capacity of this test-meter can be varied at will by means of a plurality of windings. To understand the utility of an adjustable carrying capacity it should be noted that a meter generally operates most accurately at full load and that as the load is decreased the meter is likely to become inaccurate. This is because it is impossible entirely to eliminate friction from the bearings and contacts of a meter armature or to keep this unavoidable friction at a constant value. Suppose this friction to vary sufficiently to cause an inaccuracy of 1 per cent. at full load and full torque, then at one-half load and one-half torque the proportion of this same friction variation to the torque would be doubled and the inaccuracy would also be doubled. Similarly at one-quarter load the inaccuracy would be increased four times, and at one-tenth load ten times. Suppose it be required to test a meter of 15 amperes capacity. On full load a corresponding 15 ampere winding of a test meter could be used with a high degree of accuracy. On a light load, however, say 1.5 amperes, both meters would be subject to the serious light-load inaccuracy above noted. In the latter case an adjustable ampere capacity in a test-meter can be utilized by changing, say from a 15-ampere to a 1.5-ampere winding, thus restoring the test-meter to full-load conditions of torque and accuracy. Meters of widely varying capacity have to be tested in practice and a test meter should accordingly be equipped with at least three different current windings and two different pressure windings.

A test-meter in use by the writer can be started or stopped at will by means of a switch, the meter under test meanwhile rotating continuously; in practice this test-meter is allowed to rotate only during the interval that the meter under test takes to make 1 or 10 revolutions. A comparison of the watt hours corresponding to the latter revolutions with the true watt hours as recorded by the test meter shows instantly whether the rate is fast, slow or correct. Explanatory of the relation between armature revolutions and watt hours, it may be noted that integrating watt-hour meters have what is called an armature or disk constant. Generally speaking, this armature constant in any particular meter is the number of watt hours corresponding to one armature revolution. Hence, the number of revolutions multiplied by the constant gives the watt hours. If either of these factors—revolutions or constant—be made equal to 1, 10 or 100, the multiplication necessary to obtain the watt-hours resolves itself into a mere shifting of the decimal point. Accordingly, in the case of the meter under test, 1 or 10 revolutions are taken and therefore the constant of that meter with proper location of the decimal point becomes equal to the recorded watt hours. The true watt hours can be similarly obtained from the revolutions of the test-meter, since in the latter the constants are arranged decimally, and it can at once be seen whether the consumer's meter records more or less than the true energy.

Accurate and cheap calibration is, however, of comparatively little value if a meter soon returns to its former condition of inaccuracy, therefore in old meters appliances should be provided for increasing the permanence of calibration. Owing to the advance of the art modern meters are fairly reliable, but their improvements are not generally applicable to the older forms. Suitable appliances have, however, been developed, chiefly by the large operating companies, with the result that meters manufactured some ten years ago can now be made at least equal in efficiency of operation to the most modern ones. Among the most prominent of these appliances are the adjustable friction compensating coil, the cupped, or concaved, diamond bearing and a means for correcting the disposition of the drag-magnets relative to the field coils.

The friction compensating-coil in operation carries a current of constant value and can be moved into such proximity to the rotating armature that its accelerating effect exactly neutralizes the retardation due to friction. Commutator friction increases very rapidly when a meter is first put in service but after a time it assumes practically a permanent maximum value. If at this time the compensating device be adjusted, a great part of the inaccuracy due to commutator friction will be permanently removed.

The cupped diamond bearing is partly the result of what has been termed by Lockwood the "cross fertilization of the sciences." Diamond being the hardest known substance, was long recognized as the most desirable bearing material, but it seemed impossible to get anyone to grind out a nicely curved and highly polished cavity in a diamond to receive the lower end of the vertical steel shaft. In the search for a new optical effect, however, the lapidary art has so developed that no serious difficulty is now experienced in satisfactorily cupping the surfaces of a diamond. As a meter-bearing it seems to embody the ultimate degree of perfection, the initial friction being a minimum and the wearing qualities a maximum. It is especially necessary in the old types of commutator meters with their very heavy rotating elements, because in these meters the material next in hardness to the diamond and which is generally used, sapphire, quickly breaks down in service.

---

*Paper presented at the 196th meeting of the American Institute of Electrical Engineers. New York, April 28, 1905.

The object of changing the disposition of drag-magnets is to prevent meters from running fast after being subjected to the tremendous currents resulting from short circuits. In old meters the stray flux thus produced found a convenient path along the drag or braking magnets; this tended to demagnetize them, thus causing the meter to record more than the true energy. Van Vleck found by changing the disposition of the magnets so that the stray flux traveled across instead of along them, this effect was minimized and manufacturers changed their designs accordingly. Old meters can now be modernized in this respect by removing the magnets and attaching additional small bases thereto, the drilling of these new bases permitting the magnets to be remounted in the meter at right angles to their former positions.

In conclusion, it may be stated that this general system of overhauling has been productive of excellent results and is coming into extended use as the importance of maintaining meter accuracy becomes more fully realized.

ELECTRICITY LEAFLETS.

BY NEWTON HARRISON, E. E.

ELECTROPLATING, REFINING AND STERILIZING.

Treatment of Plated Articles.—The two courses of treatment to which the electroplater subjects articles undergoing plating may be classified as, first, that before plating for the purpose of securing electrical cleanliness, and second, that after plating in the nature of finishing. The following indicates this classification:

BEFORE PLATING.

Article may be washed in water, pickled in acid or scoured in lye.

AFTER PLATING.

Article may be scratched, buffed, polished or burnished.

Processes Before Plating.—Although cleanliness is above all the primary consideration, it is only obtained with respect to the surface of the metal by the use of vats of water, caustic soda and dilute acid. The surface of the article to undergo plating may have to be polished; it is then dipped in the hot lye solution to remove all traces of grease, then into the acid to remove any film of oxide present, and finally it is well washed in clean water.

Quicking Process.—When silver plating, one of the most prevalent platings in vogue, is in view, the copper surface is treated with mercury to secure a good foundation. A dilute solution of nitrate of mercury is applied, which forms a metallic precipitate suitable for the rapid and effective deposition of silver.

Processes After Plating.—The scratching, buffing and polishing of plated articles is a purely mechanical one. Its object is to remove metallic excresences, smooth the entire surface, and finally to give it the high finish looked for in such articles. The scratching is done by means of a wheel of brass wire projecting radially, which when rotating at a high speed acts as an effective scratch brush. The buffing is accomplished by the use of canvas wheels, composed of disks of canvas held at the center with the edges free. Buffing paste or powder is applied and marks of the scratching removed. The polishing is done by means of rouge or other fine polishing powders. The wheel may be of leather or walrus hide, by means of which a mirror-like surface is readily obtained.

Coloring Copper Surfaces.—A copper plating can be rendered artistic by the following means: To obtain a rich brown color, the object must be dipped into a very dilute nitric acid solution and heat gradually applied. By this process any shade of brown can be reached, which will possess great permanency. A fine black finish can be obtained by dipping the article into a weak solution of platinum chloride. This shade may be regulated by the strength of the solution and time of dipping.

Nodules on Plated Surfaces.—It is not necessary to employ more than a limited EMF. for plating; an EMF. which is different for each different metal used as an anode, or for each different bath. If too high a pressure is applied, but the supply of current is limited, a series of protuberances will appear. These nodules will dot the surface of the plating in a disagreeable manner and are entirely due to too weak a current at too high a pressure. A certain current per unit area of cathode surface is absolutely essential to correct results, the pressure of course not being excessive.

Cause of Stripping or Peeling.—One of the reasons why a dip into an acid bath is so necessary, or, as it is called, why pickling is employed, is to remove the oxide film which settles upon the surface of many metals and acts as a partial conductor to the current. Even though the conductivity of the surface be good, still there is no intimate contact between the coating and the cathode. Such a plating can easily "strip," that is, be peeled off. The removal of the oxide by polishing or by chemical means will insure a good deposit of metal. The pickling is always preceded by the lye solution, which if hot removes grease and, after washing, the acid solution follows.

Vats for Nickel Solution.—The nickel solution is frequently poured, after being made up, into wooden vats lined with lead. The lead joints are not soldered but burnt together. Nickel can be deposited on copper, iron, brass and steel by a solution in which the crystals of the double sulphate of nickel and ammonium have been dissolved. The crystals are green in color and may be procured in the way of regular goods from any electro-plating supply house. The vats are about 3 feet wide, 6 feet long and 30 inches deep, although the dimensions vary according to the work. Enameled vats are preferred by some platers because they possess strength, durability and insulating properties because of the coating. They are made of many sizes such as 1, 5, 10, 20 gallons, etc., up to 50 or 100 gallons capacity. All vats must have a rim of wood around the upper edge raised above the vat proper. The copper rods supporting the anodes and cathodes extend across, resting on this support.

Silver Salts and Solution.—Effects of a most artistic nature are obtained by a proper handling of a silver bath in electro-plating. The silver salts may be considered as represented by the chloride, nitrate, cyanide, acetate sulphide and oxide of silver. The cyanide of silver solution is used almost exclusively for silver plating and is made in the following manner: A solution of cyanide of potassium is carefully mixed, the preparation being made with well-filtered or distilled water. A solution of nitrate of silver is also carefully prepared under the same circumstances. The cyanide solution is then added slowly to the silver nitrate solution until a thick white precipitate is obtained at the bottom of the vessel. This white flocculent mass is washed with pure water several times until thoroughly cleansed. A new solution of cyanide of potassium is prepared and introduced gradually into the precipitate. The result of this operation will be the redissolving of the white mass and a new solution to which is given the name of "the double cyanide of silver and potassium."

Pointers in Silver Plating.—Successful silver plating can only be accomplished by patience and a strict adherance to the rules of cleanliness. The ultimate meaning of cleanliness with respect to the solution will be an ability to use the same solution *for years* if it is occasionally filtered or a little new cyanide added to replace or strengthen the old and make up for the losses due to evaporation. The following items of information are of value:

A good silver plating—the coating bright and natural looking.

A rough silver plating—the result of two much current.

A gray silver plating—the result of too much current.

A black silver plating—the result of too much current.

Distance Between Anode and Cathode.—If an object suspended from the cathode has many projecting parts presenting an irregular surface to the anode, considerable distance must be preserved between the anode and cathode. The advantages of this will be in a more uniform distribution of the current and consequently a more uniform coating of silver. The edges are apt to take on a rough deposit even under the best of conditions. The larger surfaces will plate very smooth and even unless very much curved. If the general character of the object being plated is curved it will be best to use an anode curved as far as possible in the same manner to obtain a fairly uniform series of paths through the liquid. In the plating of sideboard utensils, such as pitchers, sugar bowls, etc., the plating is only successful by means of special care in this respect.

The process of evenly plating statuettes or busts without destroying their contour is also a question of preserving equal current paths between them and the anode.

Iron Plating or Steel Facing.—For the steel facing of electrotypes or any other useful purpose, a coating of pure iron may be deposited from a solution made up as follows: "To each gallon of water dissolve one pound of carbonate of ammonium, and dissolve iron into the solution by passing a strong current from an anode of iron until a deposit appears upon a clean copper cathode. A few ounces of carbonate of ammonium should be stirred into the bath once a week. The anode, which should be large in proportion to the work, must be cleaned occasionally." Another solution employed for the steel facing of plates is made up as follows: "Prepare a solution of sulphate of iron, and another of carbonate of ammonium. Add the latter to the former until the iron is precipitated; pour off the liquid portion and wash the precipitate. Take a bulk of sulphuric acid equal to the volume of the solution required, and dissolve the iron precipitate in it to saturation. If there should be any free acid it will retard the working; it is therefore usual to evaporate the solution a little. From either of these solutions good iron can be obtained by a current of from three to four volts. The anode is always of iron, and the cathode of copper. The anode is from five to eight times larger than the cathode to prevent the solution from becoming acid. It is also advisable to have the anode in solution when not in use and to connect it by a wire to a cathode of platinum or copper to prevent the formation of acid and to keep the bath as dense as possible. The metal obtained is usually *as hard as steel*, but becomes soft and malleable after heating. It is very important to have a solution which yields a crystalline and very hard coating of iron. A coating obtained from a solution of sulphate of iron and chloride of ammonium yields an exceedingly hard deposit of the purest iron, and it is thus well suited to the coating of small and very fine electrotypes of steel engraved plates. Plates coated in this solution, have been known to yield as many as 10,000 impressions in printing, all sharp. All solutions made from sulphate of iron simply, are very troublesome and are constantly acted upon by the air, thus spoiling the solution. The salts in these solutions pass to a higher state of oxidation by absorption."—Urquhart. Air effects iron solutions rapidly, therefore they must be protected from the same as far as possible. Oxygen is rapidly absorbed and may appear in combination with the coating at the cathode. Charcoal iron is the purest to use as an anode, the next is wrought-iron in this respect. If the solution is slightly heated, it will act much better in plating work. Acid and ammonium carbonate can be added occasionally to compensate for the oxidized salts. This must be so carefully done that the general composition of the bath is not changed. When attempted by beginners this form of plating is full of holes, due to too much free acid in solution and a heavy current. Acidity can be held in check by the use of litmus paper for testing for this condition and when it is found to be present neutralizing it. An oxidized solution may be deoxidized by passing a current through it for some hours between an iron anode and copper cathode. A little glycerine may serve to protect the solution from the effects of the air, though a risk to employ.

Other Uses of Electricity.—The application of electricity to produce electrochemical changes is not limited to its use for the plating process alone. It is employed as the agency by means of which refining processes are carried out, germ laden masses of matter and infected water rendered innocuous, and new compounds produced. It is to be noted that electrochemical changes are those in which a transposition of atoms occurs without any other outward signs than perhaps those due to bubbles of gas. On the other hand, the use of electricity for the manufacture of new industrial products, such as aluminum or carborundum, is attended by the development of intense heat. This cannot be included in the category of electro-plating. It is evidently a phase of the use of the electric furnace. The applications of electrical energy may therefore be considered from these standpoints with reference to the production of such materials as follows:

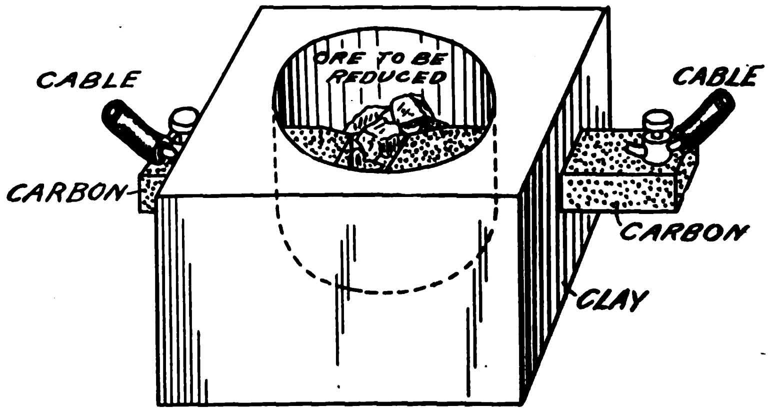
ELECTRIC FURNACE PRODUCTS.

1. Aluminum.
2. Carborundum.
3. Calcium Carbide.

ELECTRO STERILIZING.

1. Of drinking water.
2. Of city Sewage.
3. Of waste products for refilling ground.

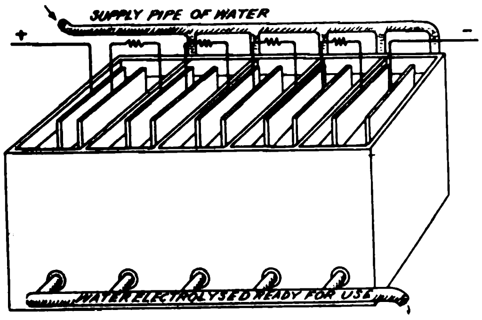
Aluminum.—This light, silvery looking metal can only be cheaply obtained by means of electricity. It is a distinctively electrical product in a commercial sense, derived from the electric furnace by the melting of aluminum bearing ore.



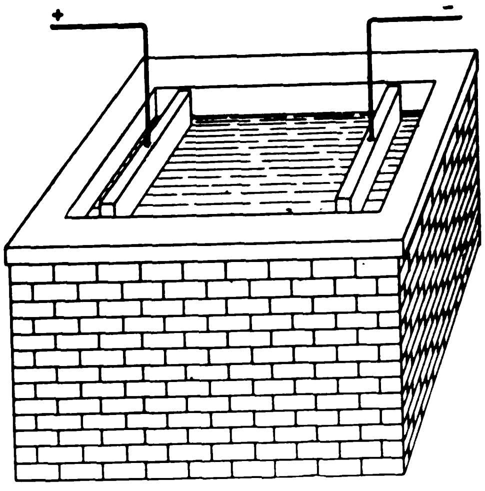
PRINCIPLE OF CONSTRUCTION OF AN ELECTRIC FURNACE.

The heat of the furnace and to some extent electrolytic action gives rise to the pure metal. The calcium carbide product, from which acetylene gas is obtained, is due to the coalition of lime and carbon in the electric furnace. Carborundrum is also obtained in a similar manner by the conjunction of two foreign bodies fused by heat into an industrial product. Thus aluminum the metal, calcium carbide the gas producing chemical, and carborundum, a substitute for emery, and superior to it, are the first practical yield of the electric furnace. In this furnace the molten mass is the result of the current passing through high resistances caused by imperfect contact and a rising temperature.

Electro Sterilizing.—It has been proposed on many occasions by scientists and inventors to sterilize the drinking water of large cities during plague periods by electricity. The germs of typhoid are peculiarly active in water, which in fact, is now considered as the most communicable means of establishing it within the system. Other germs may be transmitted in a more or less malignant form through the medium of water. Whether it can be proved directly or indirectly that this is the case, public sentiment requires as a measure of protection that the water be pure. To secure this end, it has been subjected to the effects of a current of electricity, the influence of which is dedestructive to animal life. That it undoubtedly renders the water under suspicion free from active germs has been substantiated in many cases. Though not deemed a practical process on a large scale, electricity has been employed to destroy the virility of germ life in sewage or other refuse utilized in many instances for reclaiming ground. The process is called filling in, and was carried out extensively at Riker's Island near Hell Gate, where the refuse was thoroughly treated before used for filling. The spread of disease is unquestionably due to the non-destruction of infected matter. This may be partly the result of bacteria in the air finding a suitable medium, or from the refuse of communities not provided with adequate sewage facilities. In this latter case disease cannot be stamped out unless either chemical or electrical methods of obtaining immunity are secured.

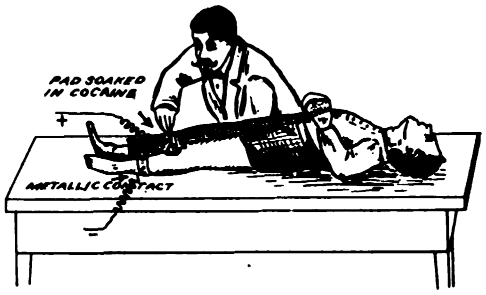


System employed for purifying water by electricity at a large packing plant in Jersey City.



Destruction of virulent germs in city waste by means of electricity.

Cataphorisis.—The transmission of a drug like cocaine from a sponge into the human body by means of electricity is entitled cataphorisis. If the negative pole of a battery is connected to the human body and the positive pole attached to an electrode in the form of a sponge or pad of absorbent cotton dampened with cocaine is applied to the gum or face, the region in contact with the positive electrode will become anæsthetized. The current carries the drug into the tissues freely and prepares them for surgical operations without hypodermic injection being necessary. In dental surgery this practice has been introduced to some extent by Dr. Morton, and on some occasions put into practice where other sensitive parts of the body have undergone operation. The current seems to carry the drug without difficulty and without chemical change into the tissues. Dr. Frederick Peterson conducted a series of exhaustive experiments in this field and established many interesting principles.



Producing local anæsthesia on the leg by means of cataphorisis.

Under the direction of the Bureau of Equipment of the Navy Department an electric telegraph "flash" was sent around the earth from Washington, D. C., on May 3 in two directions. A new world's record was established, the current encircling the globe in exactly seven seconds.

THE STARTING OF ROTARY CONVERTERS.*

BY SYDNEY WOODFIELD.

The method of starting rotary converters is a problem which merits every consideration on the part of the designer responsible for laying out large sub-stations. Capital cost, important though it be, should not be allowed to stand in the way of efficiency and a little extra capital may well be expended in securing the best method of starting promptly after the complete shut-down of a sub-station. As is well known, rotary converters are perhaps more satisfactory on low frequencies although they are built for 60 cycles with success. In methods where synchronizing is necessary it must not be forgotten that this is more easily done with low frequencies than with high, as, obviously enough, the beating of the synchronizing lamps will be about two and one-half times as frequent in the case of 60-cycle machines as it would be with 25-cycle ones and, furthermore, for the same time error in throwing in the switches, the former machine gets out of phase by an angle nearly two and one-half times as large as in the case of the lower frequency machine, assuming the same speed difference in both cases. Hence it will be seen that low frequency machines can be synchronized much more expeditiously than high frequency ones.

The following methods cover all that one is likely to meet with:

(a) Starting from the direct current end.

(b) By means of low voltage taps from the transformer.

(c) Compensator.

(d) Induction motor, i.e., mechanically.

(e) Running up with the alternator.

(f) Switching direct on to line.

Under (d) it should be noted, one includes all mechanical methods; for instance, all the machines could be fitted with pulleys and one run up from the other, the first machine being started by (e).

(a) This method is extremely simple, the rotary being run up as an ordinary direct current motor by means of a starting switch; the correct speed being obtained by field variation, using the ordinary field rheostat, the converter is then synchronized and put on the line. It is of course necessary to have direct current at a suitable potential available for starting the first machine and where a battery is located in the sub-station the case is considerably simplified. If there is no battery, an induction motor-generator of a suitable size will amply repay the slight increase in cost. In a large sub-station it is obviously undesirable to supply a starting switch for each machine; a small pair of bus-bars may be run the whole length of the rotary panels, and one starter used for the whole sub-station, as shown in Fig. 1. This arrangement permits of the first machine being run up and synchronized and thrown on the direct current bus-bars, the battery being again used independently for the other machines, or, if desired, any converter can be started from the main direct current bars. In the latter case, and also if the system is arranged as shown in Fig. 2, synchronizing becomes somewhat difficult at times owing to variations in the bus-bar voltage; moreover, the former connections allow of the battery being charged from any particular machine by means of a regulator, without complicating to any serious extent the alternating current board. If a battery is not located in the sub-station, the same wiring arrangement could still be used with the induction motor-generator, the generator taking the place of the battery in the diagram of connections.

---

*From the "Electrical Review," London.

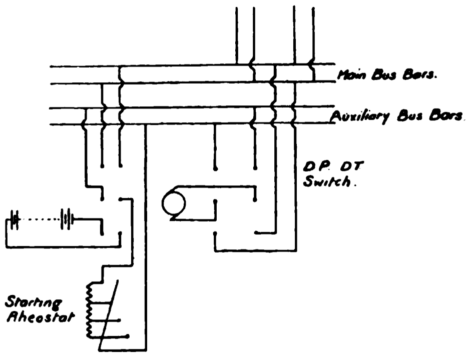


FIG. 1.

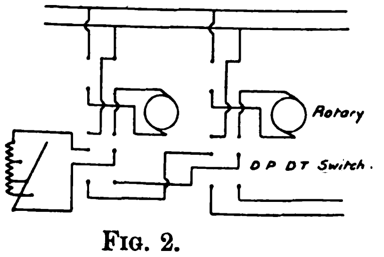

FIG. 2.

In the case of both three and six-phase converters (except with six-phase diametrical or double Y connections) the slipping brushes should be permanently connected to the transformer secondaries, without touching the alternating board at all. This is a very important point since owing to the low alternating potential the cables must be very heavy, and consequently, costly, and furthermore, the inductance of large cables is very high. It will be seen, therefore, that no low-tension alternating switches, ammeters, etc., are required and the low-tension cables are kept as short as possible, which tends towards increased efficiency.

Diametrical connections are now commonly used, as the higher voltage on the slip rings (the ratio .707 is the same as for a single-phase rotary, as against .612 for the "delta" connections) allows of lighter low-tension cables and only one secondary per transformer is required. With these connections, however, the converter cannot be started from the direct current end unless low-tension switches are provided, since, assuming the machine at rest, the commutator brushes may be resting on segments connected to bars which tap on to slip-rings 180 electrical degs. apart. In a two-pole machine, the two halves of the armature windings would be practically short-circuited by the secondary of one of the transformers, or shunted to such a degree as to make starting by this means commercially impossible. Under normal conditions of working it is better to synchronize, yet under exceptional circumstances—as, for instance, after a complete shut-down, one is anxious to get the current on the line again as quickly as possible. Under these circumstances the machine may be run up from the direct current end to a speed a little above synchronous speed, the direct current switches should then be pulled out and the machine thrown on to the alternating bus-bars without synchronizing. Care should be taken, however, to pull out the armature switches before the field switch, otherwise disastrous results will ensue. This method, as a rule, will cause no trouble if the system is fairly liberally designed or if the converter unit is small compared with the generator capacity.

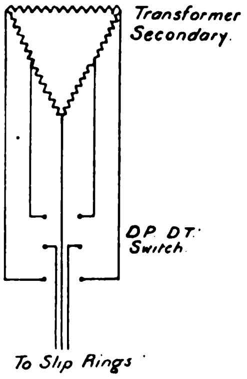

FIG. 3.

From the foregoing discussion it will be seen that starting from the direct current end gives very good results, in fact, it is perhaps the simplest and least expensive.

(b) The second method of starting, viz., by throwing the alternating current on to the slip rings at reduced potential, this lowering of potential being obtained by means of taps from the transformer secondaries as shown in Fig. 3. As is well known, the converter is self-starting from rest; when connected to the polyphase circuit it starts and runs up to synchronous speed. In converters having laminated field poles the effect is due to hysteresis, while in the case of solid poles, foucalt currents add to the starting torque by reason of their demagnetizing effects. The torque is produced owing to the attraction between the alternating currents of successive phases upon the permanent field of the induced currents which are brought into existence by the preceding phase. It will be seen, therefore, that the torque is but small, and, as a rule, about three times full load current is required to start the converter from rest. Since the large starting current which lags in phase by a considerable angle would, if drawn from the line, produce a large drop of voltage in the lines and entirely upset the regulation, besides being detrimental to the running of other plant on the circuits, taps are brought out from the secondaries of the transformers, giving one-half the normal slip-ring potential, thus allowing the machine to start up with about one and one-half times full load current. From the diagram of connections it will be seen that a double-pole double-throw switch is required between the transformers and the slip-rings, and moreover, two extra heavy cables must be brought from the secondaries to the switch. It becomes, therefore, important to locate the transformers and switch as near together as possible in order to reduce the length of cable required. At starting the field circuit is to the armature as the secondary of a transformer to the primary, and since the field turns are very large in number compared with the armature turns, an excessive potential would be induced, reaching, perhaps, 20 times the potential across the slip-rings. In order to prevent this induced potential the field winding may be short-circuited on itself, or what is preferable, should be subdivided up by means of a multi-contact switch so that, say, each pair of poles have the spools isolated and open circuited in one position, while all spools are connected in series for normal running in the other position. It must be remembered that the induced potential will be considerably higher in machines with laminated poles than it would be in the case of one with solid poles.

If the converter is compound wound, care must be taken to see that the series winding is also open. Since the EMF. of the brushes on the commutator is at starting an alternating one with the frequency of slip below synchronism, it follows that the converter may drop into synchronism at either polarity; if the polarity is wrong, the switches should be pulled out and a new trial made, or if another source of current is available, the converter may be separately excited in the reverse direction to its own excitation; this will cause it to slip a pole and consequently give the right polarity.

This system of starting excellent as it may appear, due to no synchronizing being required, possesses the drawback that extra low-tension cable is required, and also a large double-pole double-throw switch, and moreover, the length of low-tension cable cannot be kept as short as when the slip-ring brushes are connected directly to the transformers. In the larger sizes of machines which are now designed for six-phase operation (owing to the large increase in capacity, a three-phase machine has an output of 34 per cent. and a six-phase 96 per cent. greater than an equivalent direct current generator, the copper losses being the same in each case), it becomes practically impossible to use this system of starting and if no direct current is available the induction motor method must be employed. From the foregoing it will be seen that this way of starting is, as a whole, good, as no synchronizing is required; but other considerations make it somewhat expensive, and the fact that one can never tell which polarity the converter may take, gives it an element of uncertainty, although by means of a voltmeter an experienced attendant can generally manage to throw in the field switch at the right moment.

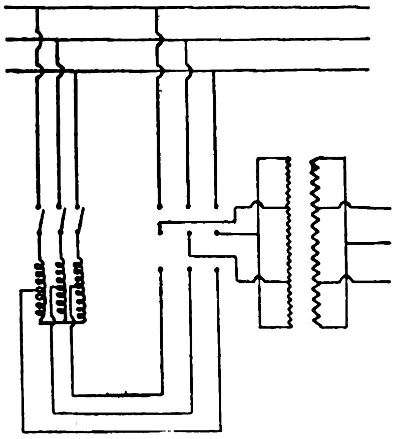

FIG. 4.

(c) The compensator method of starting acts to all intents the same as the previous method, viz., by reducing the impressed EMF. on the converter slip rings. The mode of reducing the voltage, however, is different, a compensator being used, this piece of apparatus being usually located as shown in Fig. 4, between the high tension lines and the transformer primary. The double-throw switch having to handle a small current can with the compensator be located in the most convenient position, while the large low-tension alternating cables can be kept as short as possible, as no low-tension alternating switches are required. Generally a couple of compensators may be used in a sub-station, arranged in such wise that either can be used for starting any machine.

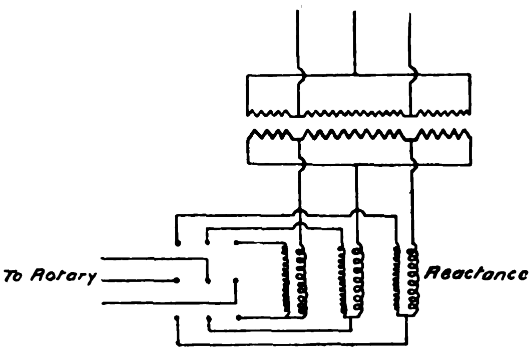

FIG. 5.

From the foregoing it will be noticed that this method possesses all the good features of the previous way of starting, more especially in not having to synchronize, and at the same time gets rid of some of the defects in the previous method, viz., the large low-tension switch, etc.

A method but rarely used is shown in Fig. 5. As is well known, the ratio of the alternating to the continuous potentials of a converter is practically constant, and in order to vary the continuous potential the applied alternating potential must be varied, a certain amount of reactance is therefore put in the alternating lines as shown in the diagram and by varying the converter field the current is made to lead or lag, thus giving a rise or a drop of potential.

The reactance is wound with two coils per core. At starting the two windings per leg are put in series by means of the double-throw switch, while for running the second winding is cut out, the transformers being connected through the single reactive coil to the slip rings.

(d) This method is largely used and is a purely mechanical one. A small induction motor is usually supplied with its rotor keyed on to an extension of the rotary shaft, the stator frame being bolted to the bearing pedestal. The stator is wound with a smaller number of poles than the rotary so that it runs at a somewhat higher speed. After the motor has been switched on to the line and run up to speed, the rotary field switch is closed and the converter excites itself; the speed of the set is then reduced to the synchronous speed by loading one phase of the rotary by means of a special rheostat supplied for the purpose. The induction motor varies in size with the capacity of the converter but is usually 6 to 10 per cent. of the full load output. This method only takes a small current from the line and is therefore not likely to upset the regulation; moreover, only small cables are required between the slip-rings and the transformers or the live side of the low-tension alternating main switches. This is a point of considerable importance as in large sizes of machines in some lay-outs the cost of cables more than balances the cost of the induction motor. This method, however, labors under the disadvantage that one cannot connect the slip-rings direct to the transformers unless a special starting transformer is used. There is no reason, however, why this should not be done as the cost would be very slight and the advantages considerable.

Taken as a whole, this method is one of the simplest and least difficult to operate and a smart man can have the set run up and synchronized in a very short time.

(e) This method of running up the machine with the alternator is an ideal way as it obviously is the one giving least strain to the plant but, unfortunately, it is commercially impracticable except in the case of the first converter to be run up.

The mode of operation is to leave the high-tension switches to the transformer primaries as well as the secondary closed so that the converter is always in synchronism with the alternator from the start. Just as soon as full speed is reached, the field switch may be closed, and if of the right polarity, the machine can be put on the direct current bus-bars.

(f) As a rule, only small machines can be thrown directly on the alternating bus-bars, for, as already explained, the disturbing effect on the system with a large machine would be prohibitive; it is therefore unnecessary to discuss this method further.

From what has been said it will at once be evident that, starting from the direct current end is preferable in all cases where it can be arranged for, and, failing this, especially with large six-phase machines of high frequency, the induction motor method is practically the only one available. However, each particular scheme is somewhat controlled by local conditions, and therefore no hard and fast rule should be adhered to.

NOTES ON THE USE OF INSTRUMENTS ON SWITCHBOARDS.[*]

BY F. P. COX.

The object of this paper is to invite discussion on what seems to be the more important features of instrument engineering, and its value to the Institute should be found in the discussion rather than in the paper itself.

In selecting instruments for any particular class of service the conditions under which they are to be used must be given careful consideration. It is evident that the conditions on a central-station switchboard will not permit of the same accuracy as could readily be obtained in a laboratory, and the information to be derived from the instrument readings does not require so exact a determination of values For example, consider a shunt ammeter; an instrument best adapted for laboratory conditions would have a shunt loss too great for switchboard service, and one designed for switchboards would have temperature errors so great that its use in the laboratory could not be contemplated. It is the author's intention to confine these notes to the conditions which are found on switchboards in central stations.

One of the most important considerations is in connection with the capacity of instruments to be used, and present needs cannot be altogether overshadowed by possibility of future growth. An ammeter whose needle constantly hovers around zero position is of comparatively little use, and an integrating wattmeter, which normally operates at 10 per cent., and frequently at less than 1 per cent. of its rated capacity, may give a false impression of the operating efficiency of the station. Under such conditions agreement is difficult to obtain, where totality meters are used and an effort is made to check them up with the sum of the individual feeders. Better results would be obtained by metering each generator, for under these conditions the meters would not be required to operate upon as low loads as they would if placed upon the feeders.

The friction of a jewel-bearing is generally considered so small that it may be neglected, but it must not be forgotten that a torque of 25 millimeter grammes is a little less than one five-thousandth of a foot-pound, and friction must be very small indeed if it is negligible as compared with this torque. Under normal working conditions, integrating instruments frequently operate at much lower torque, and even at full scale indicating instruments never approach this value.

It must also be remembered that the vibration of the board tends to impair the perfect polish of both jewel and pivot, and thus affect the accuracy of the readings. Other things being equal, it is apparent that these errors will be minimized by high torque, but they must not be altogether overlooked even under the most favorable conditions.

In deciding upon the capacity of an instrument it is necessary to take into consideration the relations between the smallest load, which it is desired to read, and the peak. It is generally considered advisable on railway circuits to have considerable overload capacity and but little attention is paid to the light-load period. On lighting circuits, however, the overload is not considered to be as important as on railway circuits and the light load is given more attention. It is usually good practice to select instruments of such capacity that under normal working conditions the needle of an indicating instrument will rest between one-half and two-thirds scale. This allows a reasonable capacity for growth and for overloads and at the same time permits of sufficient accuracy during the light-load period.

Integrating instruments should be fully loaded under normal conditions for they have an inherent overload capacity not possessed by indicating instruments; such practice insures not only low-load accuracy but also a reasonable dial registration over comparatively short periods of time. Where hourly or even daily readings of the dial are recorded it is not necessary that the registering train should have a capacity sufficient to care for several months' output. A rapidly moving dial-train permits full advantage to be taken of the meter's accuracy, and a change of one or two figures should be recorded for each observation period.

Accurate records necessitate occasional calibration and adjustment of switchboard instruments and suitable arrangements should be made for conveniently doing this work. Too little attention has been given to this feature in the past. It is frequently very difficult and sometimes impossible to introduce standards in circuits for calibration purposes. Perhaps this is a matter which should come under switchboard design rather than under instruments, but it is one of great importance and should be very thoroughly discussed.

Stray fields are always present in central stations and are frequently so strong that they cause marked instrument errors. In locating instruments on the board it is not sufficient to allow for position of bus-bars in relation to the instruments themselves, but the location of the iron framework of the board must also be taken into consideration. Magnetic fields have been carried by such iron frames and have introduced errors in instruments located many feet from the bus-bar itself. Such errors may be almost entirely eliminated by properly shielding the instrument, and no error need be introduced on account of residual magnetism or hysteresis of the iron shield. Properly designed instruments of this class show no appreciable difference between ascending and descending scales or between alternating and direct currents, and they are entirely unaffected by fields which would influence the readings of unshielded instruments as much as 10 or 15 per cent.

The use of series transformers, even on circuits of comparatively low pressure, seems to be increasing; the added convenience in removing or in cutting out instruments for recalibration, and the added security for the operators, more than compensate for the slight errors introduced by their use. This practice is particularly to be recommended in those cases where both sides of the line are brought into the same instrument, such for example as the polyphase, integrating or indicating instruments. It is also a good practice to interconnect the stationary and moving circuits and case of indicating instruments, and very often this would hardly be practicable unless series and pressure transformers are used.

Commutator meters are the only ones available for measurement of direct current; properly equipped with cupped diamond jewels, and occasionally corrected for commutator friction, they give excellent results. But induction meters with light moving element and no commutator are to be preferred wherever their use is possible.

Balanced three-phase circuits may be accurately measured by a single-phase wattmeter with a Y box. An instrument of this character records three times the energy of the phase in which the current coils are connected, therefore it should be used only in those cases where there is no possible question as to the circuits being exactly balanced.

Polyphase instruments, both integrating and indicating, are to be preferred even for balanced circuits, and for unbalanced circuits they become a necessity. Professor Nies advocates the use of three independent single-phase meters. Of course the resulting records of the different phases are interesting, and on a balanced circuit any material difference in the readings of the three instruments would indicate an error in one of them and serve as a warning that recalibration is necessary, or that the circuit has become accidentally unbalanced. In any case, it indicates a necessity for investigation. Still it is very doubtful if these advantages are sufficient to offset the added expense of three instruments and the space required on the switchboard for their installation.

---

[*] Paper presented at the 196th meeting of the American Institute of Electrical Engineers, New York, April 28, 1905.

In the measurement of polyphase circuits, the greatest care should be taken to see that the instruments are installed exactly in accordance with instructions received from the manufacturer. Sometimes a slight deviation from the connection shown on the diagram to connections which seem to be equivalent introduces considerable error, due to the instrument coils being in wrong phases; instruments are not infrequently charged with errors which should properly be attributed to incorrect connections.

THE N. E. L. A. CONVENTION.

Denver and Colorado Springs Committees Preparing Many Surprises for Delegates and Friends—Secretary Farrand's Latest Bulletin.

Denver, Col., May 3.—The approaching convention of the National Electric Light Association, which meets in Denver the week of June 5, bids fair to be the most successful ever held by the association. A splendid programme has been prepared and there is every reason to expect that the delegates will be treated to many rare surprises such as can only be furnished in the Rocky Mountain region.

The delegates will arrive here on June 5. An entertainment will be provided for them at the Brown Hotel in the evening. The business sessions will begin the following day and will cover a period of three days. There will be a few night sessions.

The feature of the programme of entertainment will be the broncho-busting contest. An old cow puncher who has been riding the range for 40 years has the contest in charge. He will have 30 of the worst "outlaws" in the Rocky Mountain region and the horsemanship of the most skilled riders of the West will be severely tested by the bucking ponies. One of the "outlaws," which will be imported from Wyoming, has never been ridden. All the cowboys in the vicinity of the ranch where he is have tried to ride him, but no man has been able to hold his seat more than a few minutes.

The ladies will be entertained by the women members of the Country Club on one afternoon of the time the delegates will spend in Denver. All kinds of novel amusements are being planned for that afternoon and the visiting ladies will be able to carry away pleasant memories of the day. The club boasts one of the finest golf courses in the country and the guests of the club will be given the opportunity of playing over the links.

The visitors will be given a smoker, one of the biggest halls in the city having been hired for this event, and the committee in charge of the matter promises that the affair will furnish a lively entertainment for the evening.

Denver will be deserted by the delegates Friday morning when they will leave on special trains for Colorado Springs. Upon their arrival at the Springs they will be taken to the Garden of the Gods and other scenic points in carriages and automobiles. These trips are always greatly enjoyed by tourists, and it may be accepted that the delegates and their friends will enjoy the trips hugely.

Did you ever hear tell of Cripple Creek? Who hasn't? It is the greatest gold camp in the world and one of the most picturesque points in the Rocky Mountain region. On Saturday morning the delegates will be taken in a special train to this point over the Short Line Railroad. This road climbs a grade of over 4,000 feet and all the country within a radius of 100 or 150 miles may be seen from the train during the progress of the trip. All of the big mining properties of the gold camp will be visited by the party during their stay in Cripple Creek and Victor. Both of these places are exceedingly interesting from an electrical standpoint and doubtless the electrical men will take considerable interest in the stations at various points over the Cripple Creek district.

In the evening an entertainment will be provided at the Broadmoor Casino, a resort which has come into considerable enviable repute within the past few years. This resort is several miles outside of Colorado Springs and has a splendid golf course.

On Sunday there will be various optional trips. Many of the delegates will undoubtedly avail themselves of the opportunity of climbing or riding to the top of Pike's Peak.

On Monday the majority of the delegates will return to Denver. The railroads have arranged for several excursions on Monday and Tuesday. The rates will be low.

The following suggestions regarding railroad tickets will be of value: On the Union Pacific, Rock Island and Burlington, tickets should read through Denver to Colorado Springs; on the Santa Fe and Missouri Pacific, through Colorado Springs to Denver. In the first case there should be a stop-over at Denver, and in the second case a stop-over at Colorado Springs on the return trip. This does not mean any additional expense, and the railroads have agreed to the stop-overs. Low rates have been obtained, but they may go lower.

Special Train to Convention.

Arrangements have been made to run a special train of Pullman cars from New York to Denver via Pennsylvania line and Burlington route, leaving New York Saturday, June 3, and arriving at Denver Monday, June 5. This train will be a duplicate of the Pennsylvania Limited. Electrically lighted, parlor, smoker, dining and observation cars will be run via Chicago at which point it will be consolidated with a similar train being made up for the accommodation of Western delegates. Application for space should be made early as the lower berths are limited. Apply to Mr. George F. Porter, Master of Transportation, 136 Liberty Street, New York City, or to Mr. Colin Studds, Eastern Passenger Agent Pennsylvania Railroad, 263 Fifth avenue, New York City.

Secretary Farrand's Latest Bulletin.

Editor Electricity.

Sir: Should any of the members of the National Electric Light Association become impressed with the idea that sight-seeing and entertainment are to be the only features—or even the most prominent features—of the 28th convention, to be held in Denver and Colorado Springs, June 6 to 11, they are destined to disappointment.

President Davis has prepared a programme that will make the business sessions better attended than ever before and he intends to have the papers and reports fully discussed. Among the numbers already in press are the following:

Wrinkles, H. C. Abell, editor.
Question Box, Homer E. Niesz, editor.
The Nernst Lamp, Its Present Perform-

ance and Commercial Status, by E. R. Roberts.

Report on Purchased Electric Power in Factories, by E. W. Lloyd, chairman.

Report on Present Method of Protection from Lightning and Other Static Disturbances, by Alex Dow.

Some Investigation of Inductive Losses, by E. P. Dillon.

Insulation Testing Apparatus and Methods, by C. E. Skinner.

The Choice of An Insulated Cable, by Wallace S. Clark.

Sign and Decorative Lighting, by La Rue Vredenburgh.

Automatic Synchronizing of Generators and Rotaries, by Paul MacGahan.

Series Alternating Current Motors for Industrial Work, by Clarence Renshaw.

Long Distance High Tension Transmission in California, by John A. Briton.

Report of Committee on Progress, by T. Commerford Martin.

The Question Box is so voluminous that it seemed for a time impossible to get the cover on, but it has finally been closed and is in the hands of the printer. Mr. Abell reports about 120 Wrinkles, and about a dozen papers and reports are still to be printed, in addition to two or three reports that will be discussed in executive session and will not be in print.

The "flow of soul" that the entertainment committee is preparing will not be allowed to interfere in any manner with President Davis' "feast of reason" and every central station manager will be amply repaid for the time and money he may expend in attending the convention.

Very respectfully,
DUDLEY FARRAND,
Secretary.

Work of the Railway Congress.

The various sections of the International Railway Congress held two sessions in Washington Saturday. The delegates attached to the second section, which discussed locomotives and rolling stock, heard an extensive report by Mr. J. E. Muhlfeld, general superintendent of motive power of the Baltimore & Ohio, on high power locomotives. Mr. Muhlfeld explained that because of the rapid development of big engines, errors in design had been committed, which resulted in locomotives of huge dimensions, whereas greater power could be obtained with less size and weight.

The following permanent officers have been elected by the various sections of the Railway Congress:

First Section—Julius Kruttschnitt, fourth vice-president of Southern Pacific, president; M. Pontzen, Minister of Transportation, France, vice-president; M. Edouard Elskes, Switzerland, and C. H. Bucholz, consulting engineer of the Erie Railroad, principal secretaries.

Second Section—M. Sauvage, France, president; M. Mentsik, Hungary, and E. T. Jeffery, vice-presidents; M. Boel, France, and D. J. Crawford, Pennsylvania Railroad, principal secretaries.

Third Section—H. T. Hodgson, vice-president of the Midland Railway, president; B. L. Winchell, president of the Chicago, Rock Island & Pacific, vice-president; Charles Jenny, Austria, and A. W. Johnston, New York, Chicago & St. Louis Railway, principal secretaries.

Fourth Section—M. Emile Heurteau, general manager of the Orleans Railway, France, president; James Douglas, El Paso & Southwestern, vice-president; M. Margot, France, and C. Peter Clark, Buffalo & Susquehanna, principal secretaries.

Fifth Section—M. De Leber, Austria, president; C. M. Hays, second vice-president Grand Trunk Railway, vice-president; W. M. Acworth, Board of Trade, Great Britain, and C. G. Waldo, American Railway Association, principal secretaries.

Ohio Engineers' Meeting.

Mr. Corwin J. Miller, secretary, Canton, O., informs us that the tenth meeting of the Ohio Society of Mechanical, Electrical and Steam Engineers will be held at Toledo, May 19 and 20. An excellent programme has been prepared, among the papers being the following: "Losses in the Power Plant," by Charles W. Harvey; "Power Plant Supervision and Accounting," by F. W. Ballard; "Some Recent Improved Forms of Electric Lamps," by Prof. F. C. Caldwell.

Proposals Invited.

Sealed proposals will be received by the Department of Water of Oswego, N. Y., until May 18, 12 o'clock noon, for furnishing the necessary generators, motors, transformers and other electrical equipment for the lake water extensions. Specifications and blank proposal sheets may be obtained at the office of the Department of Water.

All proposals must be indorsed "Proposals for furnishing and installing electrical equipment for lake water extension and must be accompanied by a certified check on an Oswego bank or a New York draft for $1,000, payable to the Department of Water of the city of Oswego. The Department reserves the right to reject any and all bids. Address F. W. Ormsby, Secretary.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED MAY 2, 1905.

Electric Railways and Appliances.

788,513. Railway Signal System. Abram L. Bower, Boyertown, Pa. Filed May 3, 1902.

788,526. Electric Trolley-Wheel. Theophile Euphrat, Norwalk, Conn. Filed Aug. 25, 1904.

788,536. Pneumatic Railway Signaling System and Electropneumatic Valve Therefor. Ernest C. Irving, Westminster, Eng., assignor of one-half to John Patrick O'Donnell, same place. Filed March 14, 1903.

788,562. Electrical Railway Signal. James W. Tatum, Durham, N. C., assignor of one-half to Robert B. Boone and John W. Smith, same place. Filed Oct. 19, 1903.

788,959. Electric Circuit and Apparatus for Railway Signaling. Henry W. Spang New York City, assignor, by mesne assignments, to Charles H. Ketchum, Yonkers, N. Y. Filed Aug. 21, 1902.

789,014. Trolley. Charles M. Feist, Sioux City, Ia. Filed Aug. 24, 1904.

Electric Lights and Appliances.

788,540. Electric-Light-Bath Cabinet. Richard Kny, Brooklyn, N. Y. Filed Jan. 3, 1905.

788,872. Automatic Electric-Light Connection for Automatic Railway Block-Signals. William Alloway, Caledonia, N. Y. Filed March 22, 1904.

788,990. System of Electric Car-Lighting. Richard D. Apperson and Albert J. Kohler, Lynchburg, Va. Filed March 24, 1904.

Electrical Machinery and Apparatus

788,518. Switch and Connection Controlling Electric Motors and Power-Transmitters. Herbert B. Coho, Mount Vernon, N. Y., assignor, by mesne assignments, of one-half to the Wheeler & Wilson Manufacturing Company and the Emerson Electric Mfg. Co., St. Louis, Mo. Filed Sept. 17, 1903.

788,566. Electric Motor and Power-Transmitter. Orville R. Van Vechten, New York City, assignor to Herbert B. Coho, Mount Vernon, N. Y., Wheeler & Wilson Manufacturing Company and the Emerson Electric Mfg. Co., St. Louis, Mo. Filed Sept. 17, 1903.

788 686. Resistance for Electrical Circuits. Hermon L. Van Valkenburg, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed Aug. 6, 1904.

788,819. Electric-Motor Starting and Stopping Device. John H. B. Bryan, Buffalo, N. Y. Filed March 14, 1904.

788,875. Electrical Stop Mechanism for Looms. Frederick M. Armstrong, Pawtucket, R. I., assignor to the Kip-Armstrong Company. Filed July 26, 1902.

788,916. Electrical Switch Mechanism. Hubert Krantz, New York City. Filed Dec. 6, 1904.

Telephones and Telephone Apparatus.

788,924. Telephone-Switchboard Annunciator. Charles T. Mason, Sumter, S. C., assignor to the Sumter Telephone Manufacturing Company. Filed June 10, 1904.

Miscellaneous.

788,563. Means for Establishing Electric Circuits. Guion Thompson, Duluth, Minn., assignor to the Thompson Safety Appliance Company. Filed July 1, 1902.

788,704. Electric Striking-Clock. Ulysses L. Collins, St. Louis, Mo., assignor to the Collins Electric Clock Company. Filed Feb. 23, 1904.

788,728. Apparatus for Electromagnetically Receiving, Recording, Reproducing and Distributing Articulate Speech, etc. Valdemar Poulsen, Copenhagen, Denmark. Filed Aug. 14, 1901.

788,732. Electric Sparking Igniter for Gas or Gasoline Engines. Joseph P. Seaton, North Birmingham, Ala. Filed Sept. 19, 1903.

788,747. Electric Display Apparatus. Edmund L. Zalinski, New York City. Filed Oct. 6, 1904.

788,762. Electromagnetic Device. Albert Favarger, Neuchatel, Switzerland. Filed Nov. 25, 1902.

788,800. Telegraphy and Telegraph Apparatus. Wesley Trafford, New York City. Filed March 15, 1897.

788,905. Electric Heater. Harry M. Hill, St. Louis, Mo., assignor to the Hill Electric Manufacturing Company, St. Louis, Mo. Filed April 25, 1904.

788,917. Electrical Device. Hubert Krantz, New York City. Filed Dec. 6, 1904.

789,030. Electric Signal System. Robert O. Johnston, Brooklyn, N. Y. Filed March 30, 1904.

789,040. Electrotherapeutic Apparatus. Charles F. Marsh, Pensacola, Fla. Filed Dec. 3, 1903.

789,082-083. Safety Device for Electric Currents. McKelvey Crites, Cleveland, O., assignor of two-thirds to William S. Rogers and Oscar Textor, same place. Filed Sept. 22, 1904; Dec. 27, 1904.

THE TELEPHONE WORLD.

Big Telephone Deal Consummated.

The controlling interest in the Frontier Telephone Company lately passed by purchase to the Consolidated Telephone Company, of Buffalo, N. Y.

The Consolidated Telephone Company, with a capital stock of $10,000,000, owns and controls the Inter-Ocean Telephone & Telegraph Company, with a capitalization of $2,000,000, and some 50 other important telephone companies in that section of the State, and is one of the most progressive Independent telephone companies in the United States.

When questioned recently as to the benefits to the telephone companies interested, and the general public at large, by this deal, B. G. Hubbell, president of the Consolidated Telephone Company, said:

"The interests brought together through this transaction have produced a happy combination, which will greatly benefit the general public as well as the parties interested.

"The Consolidated Telephone Company, through its control of the Inter-Ocean Telephone & Telegraph Company, the long-distance telephone organization for the Independent interests of New York State, and its control of the Independent telephone business in all sections of this State and adjoining States, either by ownership of important exchanges or by exclusive contracts for connection with other exchanges and toll lines, occupies a position that will be of great benefit to the Frontier Telephone Company of Buffalo, while, on the other hand, it is conceded that Buffalo occupies the strategic telephone position of this section of the country, and the Consolidated Company, and its affiliated interests are, of course, to be congratulated upon gaining control of the Independent telephone business in Buffalo.

"The Frontier Telephone Company's switchboard has the largest multiple capacity of any switchboard in the United States; its underground work is extensive and extremely well-constructed and provides for the largest possible ultimate development; its apparatus and service is excellent, and everything has been done to make an extensive and permanent foundation for this most progressive institution.

"Through the competition afforded by the Frontier Company, the class of service has been improved over 1,000 per cent. or more; the number of subscribers to be reached has multiplied over five times the number prior to competition, and a business man can now have the service of both telephone companies, reaching over 25,000 subscribers in Buffalo, for actually less money than he was forced to pay for connections with less than 5,000 telephones prior or the organization of the Frontier Company."

It is predicted that as a result of the trouble in Herkimer, N. Y., over the telephone service and rates a special election will be called for the purpose of giving the taxpayers of the village an opportunity to vote on the question of establishing a municipal telephone system. The Herkimer Business Men's Association met recently and Village Attorney Hane made a report on the provisions of the franchise held by the County Telephone Company. It is claimed the company has violated its rights and that the village board can annul the franchise.

Government Will Put In Its Own Lines.

The Government is going into the telephone business in the western part of Nevada. Failing to make satisfactory terms with the Sunset Company, the Interior Department will build a line running from Lake Tahoe, the head of the Western Nevada irrigation system, to Fallon, by way of Reno. At Reno an exchange will be located, and from it will radiate lines to all of the main lateral ditches. The system will be constructed at once of the best materials, and will be used for Government purposes only. It was not the purpose of the Government to invade this field, and it was not until after the Sunset people declined to make what were considered reasonable terms that the matter was taken up.

The Lake George Telephone & Telegraph Company, of Lake George, N. Y., has a project on foot which will mean much to the cottagers and summer residents of the east shore of the lake. It is planned to extend the lines of the company from Shelving Rock to Camp Andrews owned by I. Lloyd Green, of Poughkeepsie, and on further, south to the hotels and cottages on Kattskill Bay and at Ripley's Point. The new line will bring within easy communication the numerous cottage owners near Victoria Lodge, about Shelving Rock, Kattskill Bay and Ripley's Point. The extension of the line in that vicinity means the outlaying of a large sum of money. The company, of which George O. Knapp, of Chicago and Lake George, is the owner, now owns a private line. The new line will be modern in every particular and the best possible service will be given the subscribers. At present there is but one line to Glens Falls. In the reconstructed line there will be strung an additional set of wires.

The executive board of the Western Illinois & Eastern Missouri Independent Telephone Companies met in Jacksonville a short time ago. Those present were Frank Buffum, of Louisiana, Mo.; Ed. Glanden, Pittsfield; E. R. Conklin, Aurora, and W. W. Halliday, of the Illinois Telephone Company. Matters pertaining to schedule of exchange rates were agreed upon and a book of rates and rules will be issued in the near future.

The North Shore Telephone Company, of Port Jefferson, N. Y, has filed with the Secretary of State a certificate setting forth that its capital stock has been increased from $7,500 to $10,000, consisting of shares of $25 each. The certificate is signed by Frank H. Tuthill and Charles V. Platt.

The Minnesota Central Telephone Company has recently completed the construction in Wheaton of an up-to-date telephone system. In the main part of the town the wires are cabled and the poles have been placed in the alleys.

The Farmers' New Era Telephone Company, of Hebron, Ill., has increased its capital stock from $15,000 to $30,000.

The Henry County Telephone Company, of New London, Ia., has increased its capital from $15,000 to $30,000.

Keystone Telephone people, according to a dispatch from Philadelphia, Pa., speak with confidence of the success of the present refinancing of the company. A representative of large stockholding interests says: "I expect the plans will be announced as consummated May 10. When recapitalized, the company will have $5,000,000 stock subject to the $7,000,000 bonds, a portion of which retire the present stocks, and the floating debt will be liquidated The company will then be in a position to retain or sell its extra conduit space as it may decide."

The directors of the Killawog, N. Y., Telephone Company met recently and elected the following officers: President, Charles Tarble, Killawog; vice-president, William Dickinson, Messengerville; secretary, C. A. Brooks. Marathon; treasurer, A. C. Adams, Marathon. When their time shall have been completed free service to the patrons will be given to Messengerville, Dryden, Virgil, McLean and other points north, and Killawog Lisle, and other points as far as Binghamton.

The Wisconsin Telephone Company is planning to build a two-line copper circuit from Madison to Stevens Point. The latter place will be the switch point for Grand Rapids, Eau Claire, Ashland and Appleton. Plainfield and Portage will be on the new circuit.

The contract for building nearly seven miles of subway in Utica, N. Y., by the Central New York Telephone Company has been awarded to Joseph Dunfee of Syracuse. The job calls for an expenditure of $65,000, besides the conduits and cables, which the company furnishes. A similar large amount of construction is to be started by that telephone company in Syracuse.

Seventy-five thousand dollars of the big appropriation for the improvement of the Iowa Telephone Company in that State will be expended during the coming summer in and about Des Moines. Eight copper wire toll lines are to be built from there in four directions. Five of these lines will run to Davenport, Fort Dodge, Sioux City, Ottumwa and Council Bluffs.

Judge Murphy, of Cincinnati, O., has set aside the judgment—Pogue & Pogue—held against the Fitzsimmons Telephone Company, and through Attorney Joshua M. Dawson has given Mr. Fitzsimmons leave to file an answer. The Fitzsimmons interests announce their determination to reorganize the company on a Fitzsimmons basis entirely.

The Napa, Cal., Telephone Company will soon spend about $10,000 in the improvement of its lines in a change from a ten-party to a four-party line.

The Pleasant Hill, Mo., Telephone Company has filed a statement to show that it had made an increase in its capital stock from $10,000 to $30,000; one-half the increase has been paid.

The Christian County Telephone Company, recently organized with a capital stock of $50,000, has been granted a 20-year franchise by the Taylorville, Ill., city council.

The Federal Telephone Company is going out of business in Westmoreland County, Pa

GENERAL ELECTRICAL NEWS.

LIGHTING.

Argentine, Kan.—The Santa Fe Railway Company will build a power house and electric plant sufficient to furnish power for the Argentine shops and light for the yards and offices. The work on the plant will probably begin within the next few months. The cost is estimated at $48,000.

Ballard, Wash.—The Ballard Electric Company has begun the extension of its lighting system in this city. Of the $30,000, which it was estimated would be required for the completion of the work, $13,000 has already been contributed by local stockholders.

Breckenridge, Mo.—At a special election a proposition to bond this city for $10,000, for the purpose of putting in an electric light plant, was carried.

Central Falls, R. I.—This city, which is supplied with light by the Pawtucket Electric Company, is determined to own its own lighting plant. The present contract with the Pawtucket concern will not expire for five years, but the city council has already secured an option on a site, and at its next meeting will probably make an appropriation for a suitable structure.

Columbus, O.—The Columbus Public Service Company will increase its capital from $250,000 to $1,750,000; the electric lighting capacity will be doubled.

Hartford, Conn.—The Hartford Electric Light Company has been authorized to issue bonds to the amount of $2,000,000, and to increase its capital from $1,600,000 to $3,000,000.

Heno, O.—The Middletown Electric Light & Power Company has received the contract to light the streets of this city.

Henry, Ill.—The Henry Electric Light & Power Company, with a capital of $20,000, has been incorporated by John H. Crickenberger, Fred W. Potter and others.

Howard City, Mich.—A 10-year franchise has been granted A. O'Donnell, of this city, by the council to furnish electricity for all uses.

Little Rock, Ark.—A company, capitalized at $250,000, has been organized here to install a new electric light plant.

Laurel, Ia.—The Laurel Improvement Company has accepted the franchise offered by the city, and will begin at once the erection and installation of a $25,000 electric light and power plant.

Oxford, N. C.—A charter has been issued to the Oxford Water & Electric Company with $50,000 capital, for the purpose of constructing waterworks and an electric light plant for this town. The incorporators are Harry L. Millner, of Morgantown; W. T. Sherman, of Washington, D. C.

Pelham, Ga.—The city council has granted a franchise to W. H. Maury for an electric light plant to be put in at once.

Pleasantville, N. J.—The Shore Electric Light Company is about to be sold at receiver's sale, and will probably be operated by Atlantic City capitalists.

Traverse City, Mich.—Preliminary legislation for the construction of a $50,000 electric lighting plant is about to be taken.

Wilmington, Del.—The Wilmington Electric Light & Power Company, with a capital of $1,000,000, has been incorporated by Horace W. Gause, Samuel K. Smith, Henry P. Scott and others.

Winfield, Kan.—The special election to vote on the proposition to issue bonds to the amount of $15,000 for completing the electric light plant was lately carried.

Wautoma, Wis.—This city is to have a special election on May 11 to vote for or against issuing bonds for the purpose of building and establishing a municipal electric lighting plant.

STREET RAILWAYS.

Appalachia, Va.—Capitalists of Big Stone Gap propose to build 100 miles of electric roads, and it is said they have begun surveys.

Auburn, Ind.—An electric line will be built in and through this city.

Brooklyn, N. Y.—Many new lines are to be established by the Brooklyn Rapid Transit Company, which owns a number of franchises for the operation of cars in the suburban sections.

Bryan, Tex.—The city council has granted a franchise to W. P. Connelly, J. W. Batts and others, to construct and operate an electric car line on the streets of this city.

Canton, Miss.—A. P. Cameron, of this city, with E. W. Brister and others have incorporated themselves into the Canton & Yazoo City Trolley Company to build a line connecting the two places.

Deadwood, S. D.—Articles of incorporation have been filed by the Black Hills Traction Company, with a capital of $400,000, to build an electric road from here to Belle Fourche.

Defiance, O.—The question of building an electric road from this city has been settled and it will be continued from Ann Arbor to Detroit, Mich.

East Hampton, Conn.—Promoters of the Salmon River Power Company are planning for a trolley route from this place. The road will cost $175,000.

Fort Dodge, Ia.—An electric line is proposed from here to Webster City, and thence south to Des Moines.

Gainesville, Ga.—The Gainesville Electric Railway Company has been organized here. A. J. Warner is president, and W. H. Slack secretary of the new company.

Goldfield, Nev.—The new Nevada camp of Goldfield is planning a local electric road. It is designed to carry both freight and passengers and will connect with the Tonopah-Goldfield railroad station and all of the mines of the camp.

Great Falls, Mont.—Franchises have been granted to Dr. E. Crutcher and associates, by the board of county commissioners of Cascade County, for the building of electric railroads all over the county. The same men will at once apply for franchises in Lewis and Clark, Teton, Fergus, Choteau and other counties. The scheme is reported to be backed by a strong syndicate of San Francisco and New York capitalists.

Ilion, N. Y.—The promoters of the proposed trolley line south of this place to New Berlin, have about half of their preliminary investigation completed, and report that between here and Cedarville there are but two or three places where railroad building would be above the average cost. The promoters have strong hopes that the road will become a reality.

Janesville, Wis.—The Southern Wisconsin Interurban Railroad Company will build a trolley line to Madison.

Lafayette, Ind.—An election will be held in Fairfield and Jackson Townships to vote on a 2 per cent. tax in aid of the Lafayette & Southwestern Traction Company, which proposes to build from this city to the Covington coal field.

Lawton, Okla.—It is announced that the railroad company recently chartered for southwest Oklahoma will build an electric line through the Wichita Mountains to Fort Sill and this city.

Mankato, Minn.—The Mankato and St. Peter Railway & Lighting Company is asking for a 20-year franchise to construct an electric street railway.

New Castle, Pa.—The Western Pennsylvania Motor Power Company has been organized by Pittsburg men to construct a huge system of interurban trolley lines throughout Lawrence, Butler, Mercer and Beaver Counties. The incorporators are Alexander J. Barron William G. Doolittle, Charles E. Martin, Edward L. Allen and Ralph L. Smith. It is said that connections will be made to Pittsburg.

Peoria, Ill.—According to the definite announcement of W. B. McKinley, of the McKinley Syndicate of Interurban Railways, this city will have trolley connections with St. Louis within a year. One of the promoters says that the bonds have all been subscribed for and that actual work is now under way for the proposed new road.

Rockefeller, Ill.—The Chicago & Milwaukee Electric Railroad Company will build its line from here to Waukegan.

Springfield, Ill.—The Marion & Harrisburg Electric Railway Company has been incorporated with a capital of $10,000.

Wabash, Ind.—The syndicate which is back of the Fort Wayne & Wabash Valley Traction Company has organized a company with $550,000 capital to build a traction line from Fort Wayne to Bluffton.

Walnut Grove, Cal.—The Southern Pacific Railroad Company is planning to build an electric line from Sacramento to this place.

Zanesville, O.—The Zanesville-Coshocton Electric Railroad Company, which proposes a route touching Norwich and New Concord, is making great progress in the vicinity of New Concord in securing the right of way. It has secured free way between New Concord and Norwich and is now working along the route east.

POWER PLANTS.

Elkhart, Ind.—C. G. Conn has sold his electric power plant here to the Indiana & Michigan Electric Company.

Prosser, Wash.—President E. F. Benson, of the Prosser Falls Land & Power Company, has filed a notice at the office of the county auditor of the appropriation of 5,000 cubic feet of water per second from the Columbia River, to be diverted at Priest Rapids, for the purpose of generating electric power at that point and transmitting the same to Prosser.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 14⅞@15c.; Lake 14⅞@15c.; casting, 14⅝@14¾c.

A financial agency of Philadelphia repeats its former assertion that the plan to lease the Electric Company of America has not been abandoned. An offer of a guaranteed dividend of 7 per cent. has been made.

Dissatisfied with the policy pursued by the receivers of the Chicago Union Traction Company and the lack of progress in improving the system, John C. Fetzer, managing receiver, has sent in his resignation to Judge Grosscup.

In the $2,000,000 mortgage foreclosure suit of the Hudson River Electric Company against the Hudson River Water Power Company, Supreme Court Justice J. M. Kellogg has appointed as receiver Charles Pedrick, of Glens Falls, N. Y.

The Consolidated Gas, Electric Light & Power Company of Baltimore is offering to buy its own minority stock, giving par in the general mortgage 4½ per cent. 30-year bonds, but stipulating that the bonds must be withheld from sale for a year.

The Hanover Light & Power Company was incorporated at Albany on Saturday, with a capital of $2,000,000, to operate throughout the State of New York. The directors are William C. Janney, E. G. Du Mazuel and Frank B. Pierce, of New York.

At a meeting in New York of Twin City Rapid Transit directors plans were discussed to finance 50 miles of new extensions and to arrange for classification of directors. It is understood that the financing will be done by issue of common stock, probably at par.

August Belmont & Co., Wm. A. Read & Co. and Lee, Higginson & Co. have purchased from the Interborough Rapid Transit Company of New York $10,000,000 three-year 4 per cent. gold notes, due May 1, 1908, and have disposed of the entire amount privately to investors.

The earnings of the National Carbon Company for the first quarter of the current fiscal year are said to have been at the rate of nearly 7 per cent. on the common stock. An official of the company says there is enough business in sight to assure earnings for the entire year at that rate, or even more.

Chicago Telephone stock sold at 125 in Chicago on Friday, a drop of 10 points from the last preceding quotation, about the middle of April. The company's legal trouble with the city of Chicago concerning rates and the necessity for renewing the franchise soon have told against the price of shares.

The Northern Westchester Lighting Company of Ossining, N. Y., has been incorporated to supply gas and electricity for light, heat and power purposes. The capital stock is $1,000,000, and the directors are William J. Bagnell, Louis B. Grant, James H. Hagarty, of Brooklyn; Charles T. Lark and Ashley T. Cole, of New York, and Alexander Keogh, of New Rochelle.

The First National Bank of Milwaukee, Wis., has had assigned to it about two-thirds of the capital stock of the National Electric Company as security for loans. The bank has now taken over the control of the National Company, and John I. Beggs, Charles E. Pfister, Frederick Vogel, Jr., J. H. Van Dyke, Jr., all of whom are directors of the First National Bank, have been elected directors of the National Electric Company.

EDITORIAL NOTES.

Some Coal Statistics. In view of the enormous amount of coal annually consumed by electric lighting and power stations throughout the country, some statistics collected for the United States Geological Survey by Mr. Edward W. Parker and just made public, should prove interesting to our readers.

During 1904 the total production of coal amounted to 351,196,953 short tons, having a total value at the mines of $445,643,528. Compared with 1903 this shows a falling off of 6,159,463 short tons in quantity and of $58,080,853 in value. This decrease, although proportionately large in the figures of value, does not indicate any interruption to the generally prosperous conditions which have prevailed during the last eight years. It was simply a natural reaction from the abnormal activity which had been maintained throughout the coal-mining regions in 1903, due to the exhaustion of all coal stocks on hand by the memorable strike of 1902. In order to renew the coal stocks and at the same time to provide fuel for immediate use, the coal mines in 1903 were pushed to their utmost capacity, or, one should probably say, to the capacity of the railroads to handle the output. As a result the enormous production of 357,356,416 short tons was recorded. Prices raised high by the famine of 1902 remained high for a large part of the year and the total value of coal at the mines, before any expense of transportation or selling costs had been added, amounted to $503,724,381, an increase of $136,600,000 over that of 1902.

The production of 1904, while less than that of 1903 by 6,159,463 short tons, exhibits a normal increase when compared with the annual production during the ten preceding years. The average price for all coal mined and sold in 1904 was $1.27, as compared with $1.41 in 1903, and $1.22 in 1902.

One of the interesting features in connection with the anthracite trade is the constantly decreasing proportions of the large or more profitable sizes of coal sent to market, and the equally constant increase in the proportions of small or less profitable coal.

This in part may be attributed to the constantly growing demand for electric current. In 1890, 77 per cent. of the shipments from the anthracite regions consisted of sizes larger than pea coal and 23 per cent. represented the shipments of pea coal and smaller. In 1904 the large sizes made up only 62 per cent. of the total, while the small sizes had increased to 38 per cent.; or, putting it in another way, the total tonnage of large sizes from 1890 to 1904 has increased 25 per cent. (from 28,154,678 tons to 35,636,661 tons), while the tonnage of small sizes has increased 158 per cent. from 8,460,781 long tons in 1890 to 21,855,861 long tons in 1904.

The recovery of usable coal from the old culm banks by washing has furnished some of this increase in the shipments of small sizes and the installation of washeries at the breakers for saving the small sizes in the primary preparation of the coal has done more. The recovery from the old culm banks has averaged about 2,500,000 long tons annually during the last four years.

The statistics of bituminous coal production comprise all varieties except Pennsylvania anthracite, and include semianthracites, semibituminous, cannel, splint and block coals, and brown and black lignites. The small production of anthracite in Colorado and New Mexico is also included in the bituminous output. In 1904 the aggregate production of all these varieties amounted to 278,040,244 short tons, valued at $306,669,508, against 282,749,348 short tons worth $351,687,933 in 1903, indicating a decrease of 4,709,104 tons in amount and $45,018,425 in value. The average price a ton for all coal mined and sold, including colliery consumption, fell from $1.24 in 1903 to $1.10 in 1904.

* * *

Strikers and Autotrucks.

Even a strike is subjected to new influences nowadays. As an old sympathizer of labor says: "They are not what they were." And why not, may we ask? Chicago has just passed through a labor cataclysm in which the old feud has been renewed. It is not in criticism of the present that these few words are penned, but of the future. The introduction of new appliances in industrial life has had a remarkable effect upon the labor situation. It cannot be said that hand skill has become less, but it must be admitted that machines for taking its place have appeared in a thousand and one forms. Both crude, partially skilled and skilled labor would properly represent the classification of what is generally called labor. In the first and second case, machinery plays a most important part. In the third case, the case of skilled labor, the man is frequently indispensable. In mining, building and street railways, several millions of employes belong to the first and second category. It is from these sources that we, the general public, have best cause to know that a strike is on. A teamsters' strike, in the case of many of our large concerns today, would become a strike of autotruckists. Where there are no horses, the attack must be more or less directed against the chauffeurs. Some of our most modern autotrucks are like a wheeled bastion. It would not be surprising if in the future the more extended use of such vehicles would have the effect of modifying the violent nature of such demonstrations. It is evident that the future holds the solution of many such problems, and it is equally apparent that a pacific solution will result from the advent of innumerable types of machinery.

The wide spread of a new force like electricity for the untold industrial applications that await it will create a new attitude on the part of the worker and the employer, a feeling of co-operation and not of antagonism and a realization of the fact that the efforts of both are a contribution to our common welfare, the interruption of which can only spring from impatience or misapprehension.

The New Influence in Central Stations.

A new influence in central stations is making itself apparent. By this is meant a new type of power engine. The reciprocating steam engine has held its familiar place for half a century, but it must be admitted that the shadows of a great change are falling upon it. The steam turbine is coming to the front. The equipment called the turbo-generator is usurping the place of all other possibilities. It seems from the present outlook that the steam engine, gas engine and turbine will after a while occupy places of equal prominence in this field. But then, the turbine will win out, and for all large powers it will represent the future corner-stone of a modern central station. There are reasons for this prophesy, which judged in the light of modern progress, almost amounts to a statement of the inevitable. The natural mechanical adaptability of the turbine is in every respect calculated to inspire the beholder with a substantial estimate of its superiority in comparison with the steam engine proper. It is hardly necessary to refer to its steadiness of action, small floor space, little bulk and comparative cheapness. Its durability is of such a character that, like the dynamo, itself, it wears only at its bearings.

Such, in fact, is the new influence in central stations, which will withstand criticism and all fair tests in a demonstration of its great advantageousness.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

The faculty of the Massachusetts Institute of Technology has vetoed by a vote of 57 to 5 the proposed Technology-Harvard merger.

Mr. John Gavey, C. B., engineer-in-chief of the technical department of the British postoffice service, has been elected president of the British Institution of Electrical Engineers.

The New York Edison Company will have in full operation within about 18 months an entirely new plant, located between 39th and 40th streets, on First avenue, the cost of which will be approximately $7,000,000.

Three wireless telegraph experts left Halifax, N. S., early Saturday on the steamer Lady Laurier, a Government boat, for Sable Island to select a site for a wireless station. The station at Camperdown, at the entrance of Halifax Harbor, is expected to be completed by May 24. The construction staff at work there will then proceed to Sable Island and build the second station, which it is expected will take four weeks. These two stations will work in conjunction in reporting vessels equipped with the wireless system within 200 miles of the island.

The Salem, Mass., sewerage commission has voted to adopt electric power for pumping purposes.

"Municipal ownership," says Charles T. Yerkes, "is the commencement of socialism and a reign of blackmail and corruption. The idea is all right abroad, but it will not do here."

The Canadian Electrical Association will hold its annual convention in Montreal, June 21, 22 and 23. It is expected that upwards of 200 representatives from all parts of the Dominion will be present.

The annual meeting of the stockholders of the General Electric Company was held in Schenectady last week. The following directors were elected: Gordon Abbott, Oliver Ames, C. A. Coffin, T. Jefferson Coolidge, Jr., W. M. Crane, Fred P. Fish, George P. Gardner, Eugene Griffin, T. K. Henderson, Henry L. Higginson, J. Pierpont Morgan, J. P. Ord., Robert Treat Paine, 2d., E. W. Rice, Jr., and Charles Steele. Over 280,000 shares of stock were represented by the stockholders. The directors will meet shortly and elect officers.

From an abstract appearing in the Journal of the Chemical Society of an article by Mr. V. Gabritschewski it appears, says the "Electrical Engineer," London, that if a radium preparation and any flat object are brought for a few minutes into the immediate neighborhood of an electrified ebonite plate, and the latter is dusted with a finely-divided mixture of sulphur and red lead, a sharply-outlined dust figure of the object is formed on the ebonite plate. It is not necessary that the object should be in contact with the ebonite plate, nor with the radium preparation. If the latter is placed on the opposite side of the plate, the figures make their appearance. The author attributes this to the existence of a special force which attracts the electrical charge of the plate towards the object in its vicinity.

Mr. Thomas A. Edison says he is working at present on the motor battery for automobiles. His idea is to make it possible for a tonneau car for four persons to go without recharging for 100 miles.

PORTABLE ELECTRICAL-DRIVEN HAND TOOLS.

BY RAY HAMILTON.

"Time," says Mr. Stuyvesant Fish, president of the Illinois Central Railroad, "is the essential thing, for it is the most valuable possession which most people have." This remark, though called forth in relation to the traveling public, is none the less true in every walk of life, and applies equally to the millionaire as to the artisan.

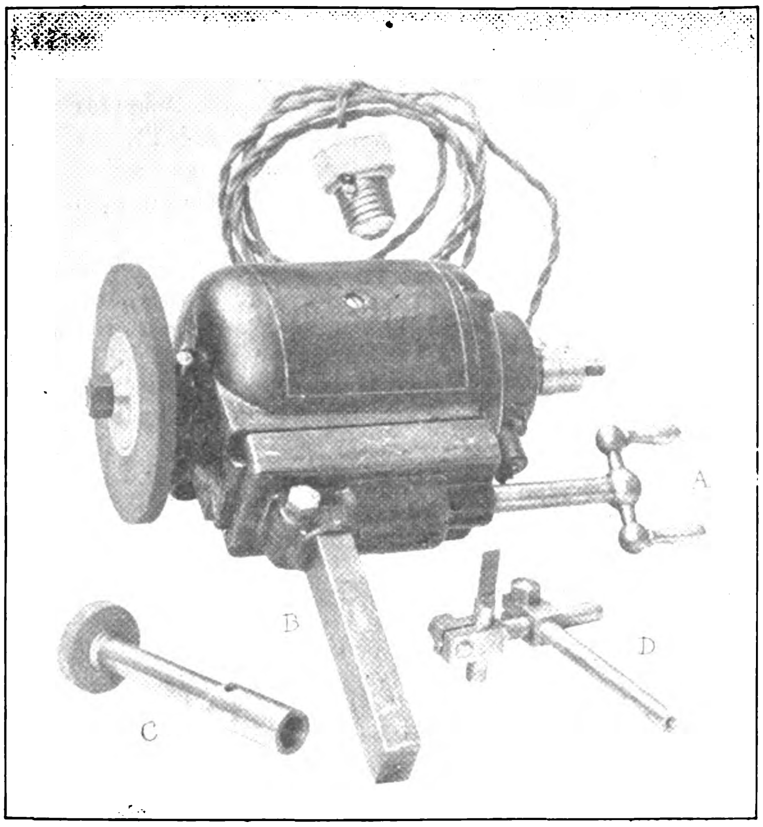

Fig. 1.—Portable Electric Grinder.

The reason machinery has replaced manual labor wherever possible, and there are indeed few places where such substitution has been found impracticable, unless it is in laying brick or milking a cow, is not alone because it does the work with more accuracy, but chiefly for the reason that it is a great saver of time, hence the old adage, "Time is money."

Time was, and not so far in the dim and distant past, since there are few still in evidence, when factories were equipped with great stretches of shafting the motion being imparted by gigantic belts connected to steam engines or water wheels and from the main line of shafting innumerable belts drove the various machines.

We do things different and better now. In an up-to-date factory a steam-electric or hydro-electric plant is installed, or, if the concern operates near a great plant, like the one at Niagara or at Shawinigan Falls, the factory is wired and each machine is connected to a separate electric motor, which is not only quicker and safer but far more economical both it its initial and running costs as against the older plan.

This progressive advance together with high-speed steel has just about revolutionized shop practice, but the end is not yet, for now portable electric tools have proven their qualities and their flexibility is one of the real marvels of the electrical designers and machine-tool-makers' arts.

The tools described and shown in the illustrations are the product of the Hisey-Wolf Machine Company, and if the reader will refer for a moment to Fig. 1, he will observe a portable electrical-driven grinder that covers a wide range of work, for it may be used for grinding centers, cutters, reamers, dies, rolls, etc., as well as for surface, parallel and internal grinding jobs of all kinds.

The shank of the grinder is clamped in the tool post of the lathe, the motor carrying on its shaft the emery wheel so that they may be set at any desired angle, in which case the wheel is moved across the face of the center to be ground by means of the handle, or the shank may be set in the tool-post of a planer, shaper or milling machine, or it can be clamped in an ordinary bench-vise. A flexible cord and attachment plug are connected and on securing the plug into any incandescent lamp socket it is ready for work.

These portable grinders are usually wound for 110 or 220 volts direct current, though in special cases they are wound from 50 to 250 volts, also for alternating current. All parts of the motor are inclosed in the shell making it dust-proof; the spindle carries taper cone bearings running in 3 degs. and 45 degs. bearings and the wear may be taken up by means of a unit on the rear end of the spindle, these being also provided with dust-proof caps. A V slide having a 3 inch travel by means of a worm through the handle A is fitted with a gib to take up the wear.

The shank B is of steel and is fitted to the hole in the V cap; it is held in position with a screw clamp so that different sized shanks can be used. The extension mandrel C is used for internal grinding by removing the regular wheel and screwing the mandrel to the spindle. A tooth rest D is a valuable attachment, serving as an index for grinding cutters, reamers, etc.; this detachable tooth-rest insures that each tooth of the cutter will be ground correctly.

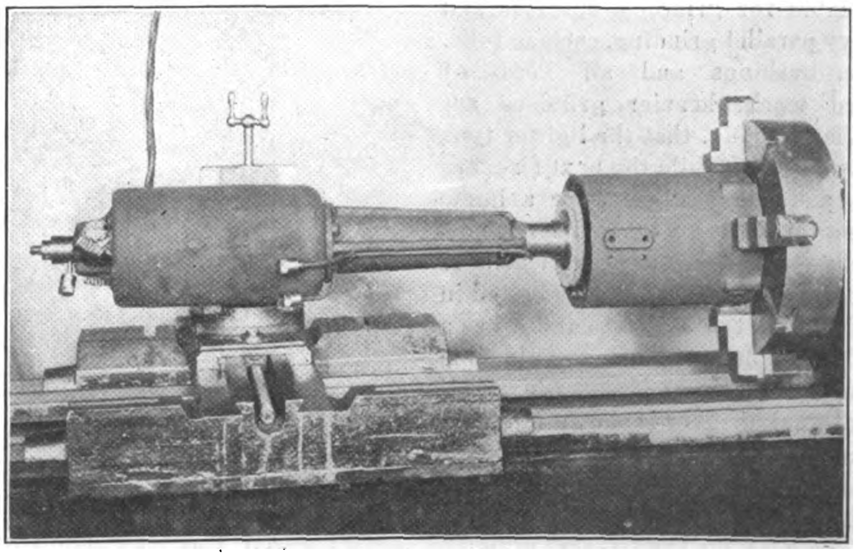

Fig. 2.—Portable Internal Grinder.

Where the grinder is set in a lathe for internal grinding the larger wheel is taken off and the extension mandrel is screwed to the spindle in its place; the mandrel C will grind a hole from ⅜ to 1½ inches in diameter. The grinder may be set in a milling machine and the cutter ground without removing it and the tooth-rest for indexing may be used as previously indicated.

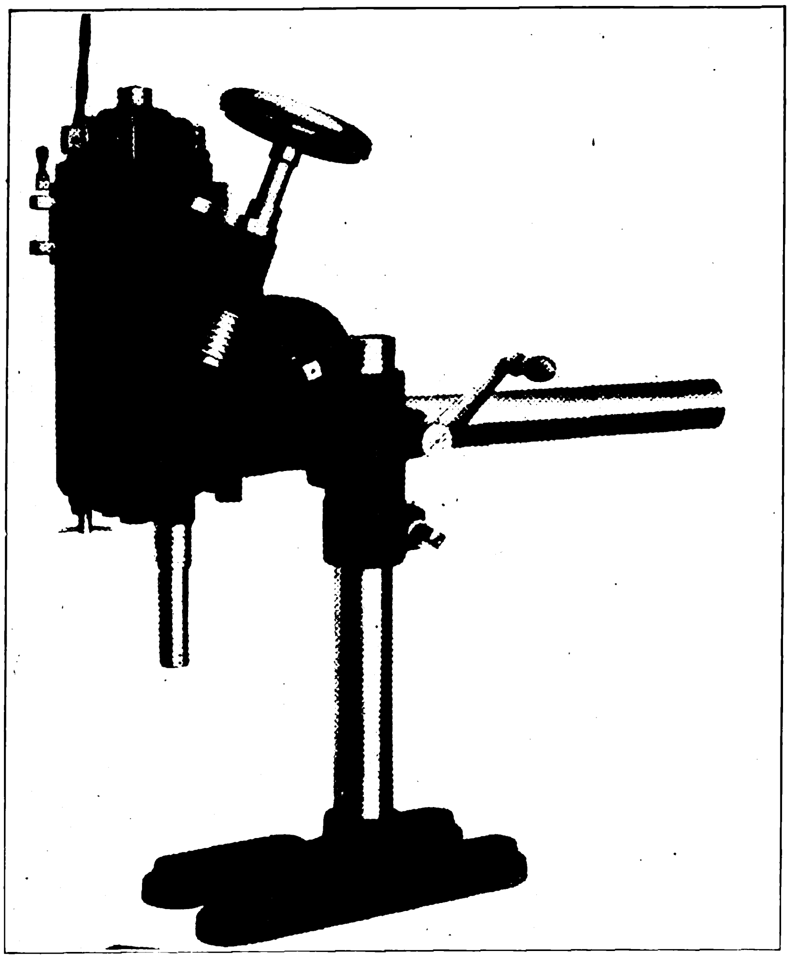

Fig. 3.—Portable Electrical Radial Drill.

Attached to the tool-post of a planer it is invaluable for grinding surfaces and for heavy parallel grinding, such as rolls, journals, bushings and all kinds of hardened work; heavier grinders are made, that is to say, that the lighter type operates on ¼ hp. while the next size has a ½ hp. and the heaviest type a horse power motor, while a 2 hp. grinder is now being constructed. In the heavier grinder the base of the angle plate is bolted in the tool-post rest of the lathe and it has a vertical adjustment to bring it in line with the centers.

An internal grinder is shown in Fig. 2 and has been especially designed for grinding and finishing up gas, steam and air cylinders, grinding out hardened dies, turning up bearings and internal cylindrical grinding of any kind. This type of machine is of the same general design as the heavier grinder, for like the latter it is bolted to the tool-post rest of the lathe. The makers furnish it for grinding to a depth of 20 inches where necessary. The minimum size hole this machine will grind is ½ inch and the maximum, 4½ inches.

Another development of these portable machine tools is a motor equipped with a flexible shape, the latter being fitted with a chuck for holding small drills or a mandrel with emery wheel for drilling, grinding and other purposes. It is pointed out that this machine is particularly adapted for pinholes or light drilling of any kind, also for grinding dies, scroll and ornamental work, while it can also be used for light buffing, polishing or sanding.

Still another handy tool of this type is the electrical aerial surface grinder; this is arranged so that it can be suspended anywhere by means of a strong spiral spring or counter balanced from the ceiling or a traveler. This machine was especially devised for rough surface grinding and the cleaning of castings and for such purposes it will be found an efficient substitute for hand filing and chipping. It is fitted with stationary end handles on an adjustable spade body handle, depending upon the class of work to be done.

A portable, electrical radial drill, shown in Fig. 3 is designed on new and original lines and is especially suitable for light work; it is virtually a universal radial drill in that it will do practically all the work of a stationary radial drill throughout the range of its capacity, and being portable it can be taken to the work instead of bringing the work to it.

The drill is provided with a 10-inch feed through the hand wheel with a quick return by hand. It has a radius of 24 inches in any direction at any angle; both the hand wheel and worm box have swivel adjustments from horizontal to vertical, thus permitting the use of the drill in corners and close places according to where the work is to be done. The spindle is fitted with a ball-bearing thrust and carries a taper socket; the drill has two speeds, changeable by means of a thumb lever at the lower end of the motor. The vertical and horizontal columns are made of hollow steel tubing and are adjustable, enabling the operator to drill at any angle and in any direction.

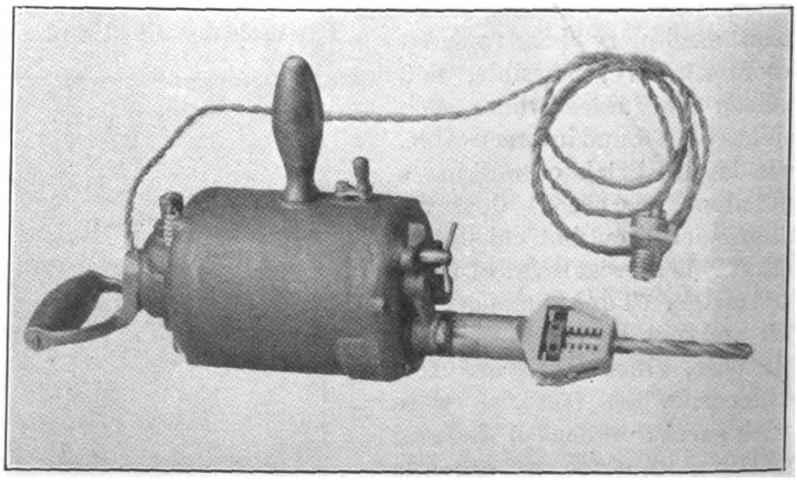

Fig. 4.—Electrical Hand Drill.

The labor-saving hand and breast drill is shown in Fig. 4, and is useful for drilling holes in wood or metal. It is designed to be used wherever the old style hand drill can be used, and not only does it save the strength of the operator, but it works many times quicker for it is driven continuously and at a much higher speed.

The motor is provided with a switch to start and stop it, so that it is under absolute control at all times, and as the switch is located near the vertical handle it is easily reached by the index finger. The chuck spindle is so arranged as to allow drilling on a line with the base of a motor and by this arrangement angle and corner drilling are permitted. The motor, which is inclosed, is suitably geared to develop the necessary power up to the capacity of the drill.

These drills may be equipped with a breast plate and side handles and used as an ordinary breast drill if desired. The drill shown in Fig. 4 has two speeds, operated by means of the lever on the front end of the motor, and with this useful device a slow speed for large drills may be used or a faster speed for smaller ones. These electrically-driven tools are built to withstand the rough usage to which this class of appliances is subjected and they are without doubt the most powerful and compact tools ever built when their extremely light weight is considered.

LIGHTING AN ASSEMBLY ROOM.

ARTICLE I.

BY W. H. WAKEMAN.

The following description of the plan adopted for controlling lights in the assembly room of a large school building is given as a matter of practical interest, because it works well, therefore may be suggestive to those having such rooms in charge at other places and prove beneficial for any hall of medium size where something more than a single switch for turning lights on and off is wanted.

A plan for doing this gradually is superior to one which makes the change all at once for two reasons, as follows:

When it is desired to relight a room that has been darkened, if the lights appear gradually the effect is pleasing, whereas a sudden change from darkness to bright light is neither pleasant nor profitable.

It is better for the machinery to make these changes slowly, especially if the load consists of lights and motors on the same generator. If lamps in other rooms are supplied from the same source, they will be affected by any sudden change, provided the assembly room lights form any considerable percentage of the whole load.

To illustrate this, suppose that while supplying current for lights and motors, requiring, say, one-half of the power of engine, all lights in an assembly room are put on at once.

Now the effect of throwing more load on a compound wound dynamo is to raise the voltage, provided the extra load is not enough to materially reduce the speed of the engine. If it is enough to make the engine run slower, which in turn reduces the travel of armature, the voltage is made less, consequently the motors may be turned into generators owing to their momentum, thus reversing the polarity of dynamo and stopping the motors. All lights will go out leaving the rooms in darkness, but so far as incandescent lamps are concerned the dynamo may be started again without delay and the lamps turned on.

It will probably be necessary to throw in the circuit breaker or renew a fuse before this can be done, and connections on both voltmeter and ammeter must be changed in order to secure correct indications of pressure between the lines and the rate at which current flows over them, but this can be done in a few minutes.

Fig. 1 shows these instruments before the reversal of polarity, and Fig. 2 illustrates the changed connections.

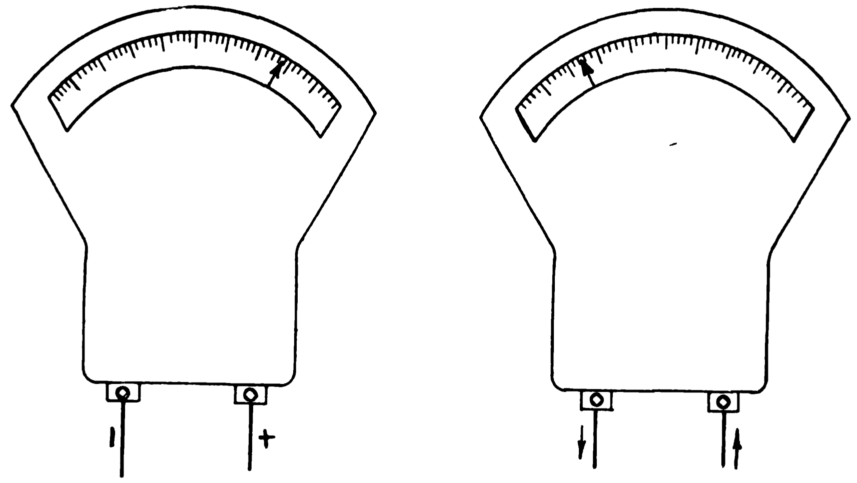

Fig. 1.

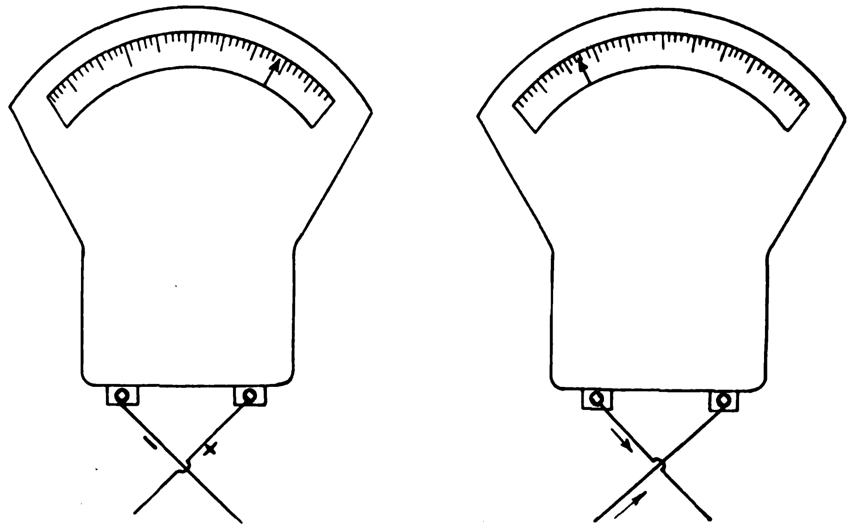

Fig. 2.

Care should always be taken to avoid putting out lights suddenly where people are assembled, as it may cause a panic in which many will be injured.

There are two ways for turning on lights gradually, one of which is to provide a rheostat or resistance box, by means of which the amount of current passing to lamps may be controlled, thus causing them to glow at first and burn brighter later on. The objection to this plan is that it is not practical to continue it for a long time, as every lamp on a given circuit is supposed to be adapted to the voltage carried, therefore if burned at any other it does them no good, to say the least, and sometimes it results in positive injury, depending on conditions.

The better plan is to wire the room so that lamps will be on several circuits, making it convenient to turn on a part of them at full voltage.

In the case which forms the subject of this article, a junction box which is also a fuse box and switchboard, is located near this assembly room where it cannot be seen by the audience, but is convenient to the comparatively large stage provided.

This is fitted for the three-wire system, but as only two wires are used to supply current from the main switchboard, the two outside lines in the fuse box are made positive, leaving the central negative.

Fig. 3 illustrates the ceiling of this room as it appears from the floor. There are four chandeliers each containing six groups of three lamps each, and six lamps arranged about a central fixture, or 24 lamps to each chandelier.

When one switch is thrown in, it lights one-half of the lamps in two chandeliers, or 24 in all. It includes three groups on each, taking each alternate group of three and every other lamp in the central group. Another switch controls one-half of the lamps in the two other chandeliers, arranged in the same way.

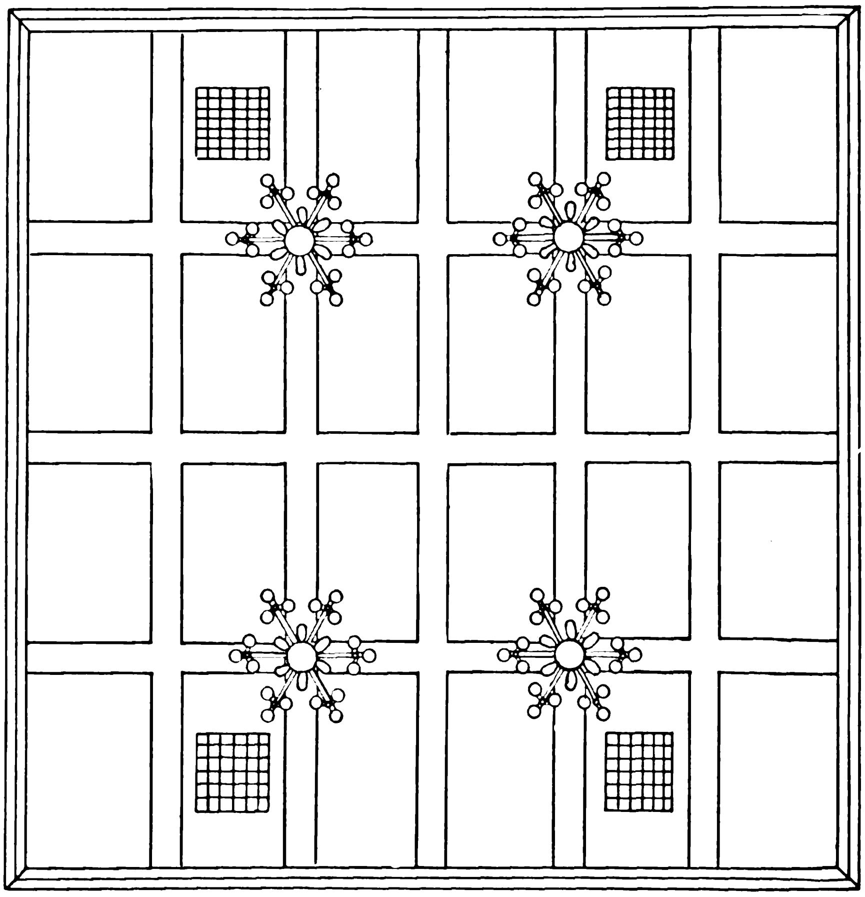

Fig. 3.

When these lamps are viewed from the floor they appear in symmetrical form, as if no more were available, and a soft light is evenly distributed throughout the room. When more is wanted two more switches are thrown in, causing all lamps to be lighted and giving the appearance shown in Fig. 3.

Whatever heat is generated by these lamps assists in ventilating the room, as it warms all air which passes out of four ventilators shown, thus causing the flues to act as chimneys.

Automatic Telephone Exchange in Vienna.

Since April 1 a 200-line automatic exchange on the Strowger system has been experimentally in use at the Berggasse telephone exchange in Vienna. According to the "Elektrotechnische Zeitschrift," provision has been made for an ultimate extension to 10,000 subscribers, if the first experiment is successful.

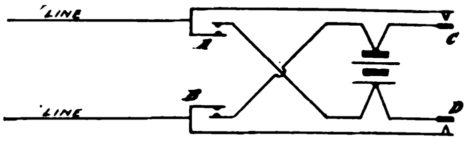
ELECTRICITY LEAFLETS.

BY NEWTON HARRISON, E. E.

TELEGRAPHY BY WIRES.

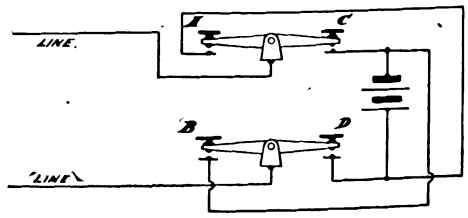
Signaling by means of electricity was attempted many years before Morse was born. It was necessary for the invention of the electromagnet by Joseph Henry to be made before such efforts could be attended with success. In all, three distinct contributors to the invention of the telegraphic system appear—first, Daniell with his constant closed circuit battery; second, Joseph Henry with his electromagnet, and, third, Morse with his crystallized invention. The Daniell cell became modified into the well-known form of the gravity battery in almost universal use in the United States for telegraphic purposes for over 40 years. The electromagnet was applied to telegraphic purposes by Morse, by means of an armature, an arm extending from it and a stylus or marking device attached to this arm which made impressions upon a piece of paper tape, passing beneath it.

The Two Systems.—Examination discloses the obvious fact that two systems of telegraphy exist. They are called the open-circuit and closed-circuit systems. The original Wheatstone or needle system is operated in such a manner that the needle, surrounded by a coil of wire, is deflected either to the right or left by means of a tapper or telegraphic key, which closes the circuit in either one direction or another. It is in fact, a reversing key, through which the needle swings as desired. It possesses two levers, the action of each when pressed controlling a particular direction of the current.

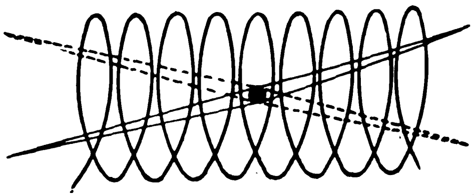


Current reversed in line, when A and B are joined to line or C and D to line.

In one case the key when pressed sends a current out over the line to the distant station. This is called a positive current because it issues from the station through the line returning through the earth connection. The other key when depressed sends the current into the earth to the distant station from which it returns by means of the line; it is therefore called a negative current. The single needle Wheatstone telegraph instrument consists of a coil arranged in a vertical position, operating a vertically poised needle which is connected to a larger dial needle. The movement or combination of movements of this needle to the right and left constitute a series of characters to the telegrapher which are readily understood and represent the code employed. When the needle is affected by positive and negative currents respectively the circuit is being closed by either one key or the other. The system is therefore one in which the circuit remains open when not in use, in complete contradistinction to the Morse system, which always remains on closed circuit except when in use.



Principle of reversing keys shown for sending positive or negative currents in the line.



The two positions assumed by needle when the current is reversed in the coil.

The Morse Closed-circuit System.—According to the data supplied by authorities on the history of telegraphy, such as Prescott, Culley or Preece, Lesage of Geneva as far back as 1774 exhibited a system of telegraphy. This, however, was electrostatic in character and therefore impractical. The information on this point, however, is interesting and presents itself in the following form:

Inventor.	Character of the invention attempted.	Date.
Lesage	Electrostatic signals	1774
Lomond	“ “	1787
Cavallo	“ “	1795
Ronalds	“ “	1816
Soemmering	Electrochemical “	1808

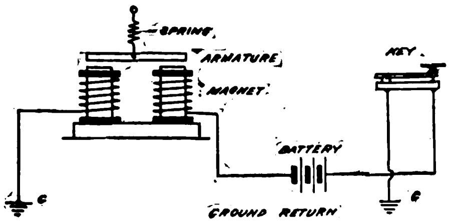
Bosscha	“ “	1855
Heaviside	Quadruplex “	1873
Edison	“ “	1873
Varley	Harmonic “	1870
Gray	“ “	1874

Then follows, in addition to these inventors, the work done in the printing telegraph by Hughes, the efforts of Cowper in 1876 and of Elisha Gray in 1893 to perfect an automatic system of telegraphy. In conjunction with this epoch making series of investigations and experiments the cable came into existence through the efforts of Lord Kelvin who invented the mirror galvanometer and the famous and unreplaceable siphon recorder. This mass of inventive work has left a permanent impression in the form of the English or European needle telegraph, the cable system for transatlantic signaling, the Morse or sounder system, the printing telegraph used in the well-known ticker and the telautograph of Gray, by means of which handwriting is transmitted with all the speed of telegraphic signaling. Among all these, the Morse sounder system, a development from a tape system formerly employed, calls for consideration. It is, as stated, a closed circuit system in which the current is always circulating through the line and instruments. Signaling is done by means of a telegraph key, which simply opens the circuit instead of closing it, as in the Wheatstone system. When thus opened a sounder is thrown into operation and gives a loud click.

The Sounder.—The sounder consists of a pair of vertically mounted electromagnets which attract an armature against the tension of a spring. The action of the key either releases or attracts this armature, the sound of which, as related to the intervals between the sounds, represents the equivalent of the telegraphic code invented by Morse. The original code was used in conjunction with tape in which a cut or mark was made consisting of dots and dashes.



Elements of a closed circuit system, including sounder, key, battery and earth connection.

The Morse code is called by the two names of International code and the American code. The latter is employed in the United States and Canada. The International code is given as follows:

A	. –	J	. – – –	S	. . .
B	– . . .	K	– . –	T	–
C	– . – .	L	. – . .	U	. . –
D	– . .	M	– –	V	. . . –
E	.	N	– .	W	. – –
F	. . – .	O	– – –	X	– . . –
G	– – .	P	. – – .	Y	– . – –
H	. . . .	Q	– – . –	Z	– – . .
I	. .	R	. – .		

The American Morse code differs in certain respects and is given in the following with numbers. The difference is in the spacing between the dots and in the use of more than four signals to represent some characters. In Y for instance, the spacing between the four dots is important as in Z. On the other hand P is made up of five dots, etc. The numbers also disclose the use of more than four signals in some instances, although no such precaution in spacing is necessary as in the alphabet itself. The various typographical signs are added to make the illustration more complete.

The American Morse is as follows:

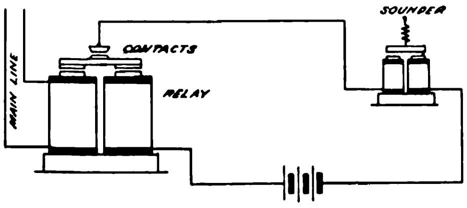
A	. –	M	– –	Y	. . . .
B	– . . .	N	– .	Z	. . . .
C	. . .	O	. .	1	. – – .
D	– . .	P	. . . . .	2	. . – . .
E	.	Q	. . – .	3	. . . – .
F	. – .	R	. . .	4	. . . . –
G	– – .	S	. . .	5	– – –
H	. . . .	T	–	6	. . . . . .
I	. .	U	. . –	7	– – . .
J	– . – .	V	. . . –	8	– . . . .
K	– . –	W	. – –	9	– . . –
L	–	X	. – . .	0	——

Punctuation marks:

Period	. . – – . .
Comma	. – . –
Semicolon	. . . . .
Colon	– . – . .
Exclamation	– – – .
Quotation marks	. . – . – .
Parenthesis	. . . . . – .
Interrogation	– . . – .
Paragraph	– – – –
Dollar mark	. . . . – . .

The American system of telegraphy is spreading all over the civilized world to the exclusion of other systems. The French, Germans and English are adopting it almost entirely at their principal telegraphic centers. It is only a question of a few more years and other methods of telegraphic communication will have become obsolete.

Purpose of the Relay.—Although the chief constituents of a simple telegraph system, consist of a sounder, battery, key and line, another important adjunct, became necessary in the shape of a relay. A relay is a device employed for the purpose of receiving the incoming signal, throwing into action a new set of batteries, and with these new cells reproducing the signal with greater emphasis. It is evident that its usefulness is dependent upon the condition of the line. If such leakage occurs, that the current becomes too weak to produce an effective signal, either due to the length of the line or the poorness of its insulation, then it is necessary to interpose an instrument which is sensitive to delicate currents. A relay is of this character, in that it consists of an electromagnet which attracts an armature over a distance not greater than the thickness of a sheet of paper with a very weak current.



Elements of a local circuit, showing relay, its contacts and sounder in circuit.

When the armature is attracted it closes a new local circuit in which is a sounder. Therefore, every time the relay operates, and its contacts meet, the sounder and its operating cells are thrown into action. A station therefore contains the main line, and in addition its own local circuit by means of which it is able to reinforce the current. In telegraph stations there is found

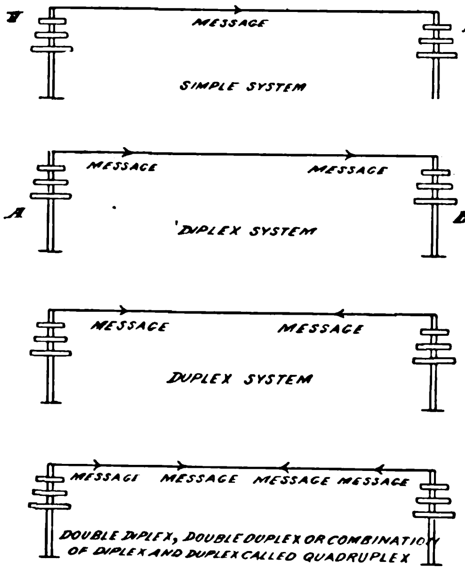
First—The main circuit.

Second—The local circuit.

A sounder has two binding posts which connect direct to the battery via the relay. The relay possesses four binding posts; two of which connect with the incoming line, and two of which complete the circuit of the sounder and its battery.

The sounder, relay and key are generally mounted on one board for convenience. The relay is really a very high resistance sounder with a very limited action, no sound, but a pair of platinum contacts connecting to the local circuit. If a sounder takes $\frac{1}{4}$ or $\frac{1}{10}$ of an ampere to operate, the relay will take about $\frac{1}{10}$ of this. The relay current is so small that it cannot be measured in an ordinary manner. It is estimated in one-thousandths of an ampere, milliamperes as they are called. A relay takes about 10 milliamperes if well adjusted, and sometimes less.

Messages Over One Wire.—The messages that may be sent over one wire at the same time depend upon the character of the apparatus at the ends of the line. The following shows the extent to which the telegraphic system has developed at the present time:



A
MESSAGE
B
SIMPLE SYSTEM
MESSAGE
MESSAGE
A
DIPLEX SYSTEM
B
MESSAGE
MESSAGE
DUPLEX SYSTEM
MESSAGE MESSAGE MESSAGE MESSAGE
DOUBLE DIPLEX, DOUBLE DUPLEX OR COMBINATION OF DIPLEX AND DUPLEX CALLED QUADRUPLEX

The analysis of the telegraphic systems in common use.

From either end—One message over the line at once—The simple system.

From one end—Two messages over the line at once—The diplex system.

From both ends—One message over the line at once—The duplex system.

From both ends—Two messages over the line at once—The quadruplex system.

From both ends—Four messages at once—The multiplex system.

From both ends—Any number of messages at once—The Delany system.

In explanation of the above it may be stated, that the simple system is merely a case of transmitting a signal, *one at a time*, over the wire, which of course is returned by way of the ground connection.

A Diplex System is one by means of which two distinct signals may be sent at the same time *from one end* of the wire without confliction and be received at the other end without trouble. These signals or messages both travel in the same direction, thus making the simple system and diplexing a line related to each other. One being only one message in one direction, the other being two messages in the same direction simultaneously.

A Duplex System permits a message to be sent from each end of the line at the same instant without confusion. It differs from the diplex as regards the direction of the messages. The diplex sends both one way, the duplex both in opposite directions at the same time.

A Quadruplex System is one in which two messages may be sent from each end of the line at the same instant, making four in all, two moving in one direction, and two in the opposite direction. This system might be called either a double diplex, a double duplex, or a combination of a diplex and duplex system. The latter idea is carried out in practice, that of using devices by which the line is diplexed and duplexed for the purpose of conveying four messages at one time.

A Multiplex System.—This idea can be carried out beyond this point, in fact to such an extent that eight messages may be transmitted simultaneously, in which case, octuple name given to the system. But a development of this order would naturally call for the use of a more and more complicated system of devices beyond the reach of human intelligence to manipulate successfully. Patrick B. Delany invented a system in which complications of this order are avoided. But a new set of difficulties appear in the invention entitled the Delany Synchronous System of Multiple Telegraphy. The difficulty, which it is claimed, has been overcome, is one from which the system derives its name. It is that of keeping in synchronism a set of levers which must rotate in perfect accord with each other, even in so far as a part of a revolution is concerned. They are situated one at each end of the line, and in their rapid rotations touch exactly the same points at the same instant on a pair of corresponding dials over which they swing. The arms themselves are connected to the line, and the dials to the various branch stations in the near radius. As the arms rotate, they touch successively contacts arranged around on the dials, the same contacts at the same instant. By this means before the telegrapher can lift his hand from the key, the arm has touched the contact connecting to his station and the signal has reached its destination through the distant arm touching a corresponding contact.

ELECTRICAL REPAIRS AT SEA.*

The applications of electricity in the navy are so many and varied in their nature, and the conditions under which repairs and the accompanying tests have to be carried out often so adverse, that in many cases ordinary shore-going methods are in a great measure inapplicable. Consequently it is very often that makeshifts have to be resorted to and rough tests applied, which would appear strange to those who are accustomed to work in the ordinary lines of everyday life.

To begin with, a man-of-war carries a certain fixed proportion of stores, instruments and spare gear, based upon the average demands as they have been represented in time past, and anything that is required outside these limits must be supplied by the ingenuity, craftiness or liberality of the torpedo lieutenant in charge of the ship's installation.

Owing to the use of electricity in the big guns and explosives generally, it is essential that there should be no possibility of tests being carried out with instruments capable of giving sufficient current, under any circumstances, to bring in an element of danger.

The two principal instruments which are supplied for all ordinary testing use the form of gravity Daniell cell known as the Minotto sawdust battery.

These instruments have been described in former articles in detail, and it will be sufficient here to remind our readers that one known as the single-cell test battery consists of a low-resistance detector mounted on a single cell, while the other consists of six smaller cells in a box with a high resistance astatic detector joined up so that any number of cells from one to six can be put in circuit by shifting a plug.

As a matter of fact, these detectors are both known in the navy as galvanometers, and are distinguished by their approximate resistances, which are respectively 20 and 1,000 ohms, but they can hardly be regarded as measuring instruments as they are not calibrated and the magnetic saturation of the needles is liable to vary considerably. The single-cell instrument is used for detecting continuity in a circuit by giving a pronounced swing, and is capable of showing as low a conductance as 1,000 ohms, roughly speaking, the deflection then being only just distinctly perceptible; the cell has an average internal resistance of 50 ohms, which with the detector in circuit is brought up to 70 ohms, and therefore it can never give a greater current than about one-seventieth of an ampere, or less than one-hundredth of that required to fire the ordinary naval fuse used for explosions. The six-cell battery is used for detecting faults in insulation and may be relied on to discover faults of the order of 40,000 ohms. With this instrument, which is used for all ordinary tests, the operator is satisfied if he can detect no movement of the needle when the key is pressed.

---

*Abstract of a communication to the "Electrical Review," London.

Both instruments are in a very portable and convenient form, and are capable of standing a great deal of rough handling. Their utility, however, does not end here for a great deal of measuring and comparison work can be done with each of them.

Every ship carries a large number of cells of the Leclanche type for gun circuits, bells, telephones and all manner of open circuit work, and it is necessary to test these cells continually to see that they are in good working order, and capable of giving the full current required. The test that is laid down for these cells is based upon their capability of fusing a certain length of platinum-silver wire, equal to that in an ordinary gun fuse, through a specified resistance.

The process of testing in this way with the instrument supplied for the purpose is exceedingly tedious in practice, and the torpedo lieutenant has other things to do besides spending the best part of his life testing batteries; consequently he is often tempted to make a short cut with that invaluable instrument, the single-cell test battery.

The methods employed must be somewhat as follows: A cell is chosen which is expected to be in good condition, and the service test is carefully carried out with it by fusing platinum-silver wire.

If it gives a satisfactory test it is put aside while the detector of the test battery is shunted by a moderate length of low-resistance wire; the Daniell cell of the instrument will not be used and is disconnected. The shunt wire is now adjusted by trial until the detector gives a convenient deflection, when the particular cell under test is joined to its terminals and the deflection is noted. Now it is obvious that any other cell which will give the same deflection when momentarily joined up to the detector is in as good condition as the cell first tested. The arrangement can very easily be carried about and the test applied to all the cells in the ship. Those which are at all doubtful can be removed and tested in detail at leisure.

Another use to which the single-cell test battery may be put, and which is useful in measuring voltage, is as a standard in conjunction with an improvised potentiometer. In this case the cell is taken as giving 1.04 volts, and moderate voltages can be compared on an ordinary black-lead pencil split in two, with divisions marked off on the wood in which the carbon lies. Care, of course, must be taken to see that the lead is not broken.

The way in which such a potentiometer is made is as follows:

A really good drawing pencil is taken and soaked in water; the glue is thus softened, and the half which has not got the plumbago embedded in it comes away fairly easily.

The remainder of the pencil is now carefully dried; a couple of notches cut close to either end are then made in the wood and a binding of copper wire wound into them so as to make good contact with the plumbago. The ends of these copper bindings can either be used as leads themselves, or have flexible leads soldered to them. The slider consists of a piece of similar wire taken once round the pencil and twisted to its own part rather tightly, so as to make a fair contact with the core of the pencil.

The arrangement is now tested by marking a half-way point and putting the slider on to it.

Two test cells from the test battery are connected to the ends, and the slider with the sensitive detector and a single cell joined in series connected to one of the ends so as to reduce the difference of potential; if the instrument is properly constructed the galvanometer needle will not be deflected. The slider is then moved until a perceptible deflection is noted, which shows the minimum scale that may be used. The wood surface is now divided off into a suitable scale, and the potentiometer is constructed.

This little device, it must be remembered, can be carried about in the pocket and applied in all sorts of holes and corners, and herein lies its virtue; the six-cell test battery, taking the difference of potential of each cell as 1.07, gives with all the cells in series 6.42 volts, while the voltage most common on board ship is from 80 to 100, hence no very material error need be expected even in testing the lighting mains, and where batteries for the firing circuits are suspected of giving a low voltage, the results are proportionately accurate.

The batteries are used in sets of three, six or ten cells, according to the kind of gun they are used for, and therefore in order to quickly test all the batteries on he upper deck after, say, a night attack by torpedo boats, when in consequence of sustained firing a considerable strain has been put on them, and another attack is expected shortly, it is easy to apply the potentiometer to the terminals of each in turn without disconnecting anything and detect at once any that seem likely to run down. The slider being set once for this type of battery need not be shifted, the deflection of the galvanometer showing at once if they are above or below the standard fixed by its deflection either way.

There is another method of calibration which is far more simple and proportionately rough; it consists in joining the searchlight resistances all in series. Each of these has a resistance of .2 ohm and can carry 100 amperes of current with safety, consequently four of these can be put across the dynamo terminals and there will be 20 volts fall each. Presuming that the pilot lamp will show approximately if the dynamo is giving its correct 80 volts, three other readings may be obtained. Ammeters can always be checked if one's voltmeter and Wheatstone bridge are in order and besides they do not intrude themselves upon the torpedo lieutenant's notice to the same extent as the voltmeter, for it must be remembered that the lights in the captain's cabin are among the most distant from the dynamo and that captains are very liable to be very low reading voltmeters on their own account and are not inclined to enter into lengthy arguments where their eyesight is at stake.

By all means let the meter in the dynamo room read only 80 volts, but at the same time let it not be at variance with the captain's judgment; he is not likely to go pottering about down below for the purpose of proving himself in the wrong, and if Mahomet will not come to the mountain there is only one course open to the market if peace is to reign among the torpedo staff.

PROPOSED NEW SUBWAY FOR NEW YORK.

Routes for new four-track subways extending the entire length of Manhattan Island on both the east and west sides, involving an expenditure of $125,000,000, were laid out formally by the Rapid Transit Commission last Friday, and will be acted upon by the Board of Aldermen.

The mayor declared that every effort would be made to have the routes approved before the bills were signed in order that the determination of the aldermen to test the constitutionality of the laws would not delay the construction of these subways.

The lines approved were for Lexington, Third and Seventh and Eighth avenues. This week the commission expects to approve of the 34th street, crosstown and the Brooklyn routes, the week following the lines laid out for the Bronx, and a week later the bridge loop, the First and Ninth avenues, and the Grand, 14th, 23d and 59th street cross-town lines.

As adopted the routes cannot be changed by either the Board of Aldermen or by the Board of Estimate, should the routes be referred to it under the new laws. The municipal authorities must accept the lines laid down by the commission as a whole or reject them entirely. The final plans provide for three subways through Herald Square, one four-tracked line through 34th street from the East River to the North River and two two-tracked lines, one through 35th and the other through 36th street, from Third avenue to Eighth avenue.

Mr. Rice, the acting chief engineer to the commission, stated that trains would be running to Battery Park over the Broadway section of the Brooklyn extension in about six weeks. He notified the commission also that the tunnel under the Harlem River was completed and had been turned over to Mr. Belmont's company by the sub-contractor. He added that trains would be running into the Bronx under the Harlem River in about six weeks.

Boston Edison Company Pushing Refrigerating Apparatus.

The Edison Electric Illuminating Company of Boston has recently exploited the sale of electrically driven refrigerating machines run upon the ammonia compression system, and particularly adapted to the requirements of cold storage in meat markets, creameries, dairies, drug stores, restaurants and hotels. The operation of the motor is automatically controlled by a thermostat in the refrigerating box; the feed of ammonia is automatically regulated by the pressure in the expansion coils, and the supply of cooling water is determined automatically by the condenser pressure. The development of these automatic devices has been the only obstacle which has heretofore prevented central stations from taking up and pushing mechanical refrigeration.

During a recent test of nearly 600 hours, a motor driven refrigerating machine was stopped automatically more than 1,500 times at the predetermined temperature of 36 degs. Fah., and started again when the temperature had risen to 38 degs., thus absolutely maintaining the inside temperature within a 2 degs. limit. Such a performance as this indicates a large saving over the cost of ice, and greater cleanliness and convenience of operation is also secured. In a heat insulated space of 4,000 cubic feet ice will maintain a minimum temperature of 45 degs. in hot weather, and will cool about 4,300 pounds of food supplies in 24 hours. Equivalent automatic mechanical refrigeration in the same space and under like conditions will easily produce 45 degs., or the usually desired cold storage temperature of 36 degs. in the smaller space of 2,300 cubic feet, and will cool about 4,600 pounds of food supplies per day.

Big Independent Telephone Company Incorporated.

The Great Eastern Telephone Company, capitalized at $30,000,000, has been incorporated in South Dakota. The company purposes operating a general telephone system, with messenger service. Its principal office is to be in Huron, S. D., and it will have a branch office in New York City.

The new corporation is in some manner connected with the State Line Telephone Company, the Atlantic Telephone Company and the New York and Eastern Telephone Company of New York City. It has been incorporated largely by the same interests.

The incorporators are Loyal Ward Reynolds, Stephen M. Conger, Eugene H. Brock, Henry N. McCay, John I. Wheaton, Edward Neuman and Elias J. Beach, of New York City, and Philip Lawrence, M. H. Lawrence, Marion Hoke and L. S. Robbins, of Huron, S. D.

This incorporation represents an important step in the extension of the Independent Telephone interests of New York and neighboring States, and there are grounds for believing that an Independent service will shortly be offered in what is called the "metropolitan district," including New York City and its thickly settled environs. The project has been laid before several important banking houses in the financial district. It is declared that the activity of the Independents in this direction is the real cause of the recent successive reductions in the scale of prices charged by the Bell Companies.

The General Electric Company sends out the statement that it is now employing 18,500 men in its Schenectady plant —the largest force it has ever employed.

End of the Railway Congress.

After one of the most interesting as well as successful meetings in its history, the International Railway Congress formally closed its sessions in Washington, D. C., on Saturday, and the delegates are now on their tour of inspection of the various railways of the country before leaving for their homes. Among the important official conclusions reached by the Congress, probably the most timely, is the resolution passed regarding rates, as follows:

"Tariffs should be based on commercial principles, taking into account the special conditions which bear upon the commercial value of the services rendered. With the reservation that rates shall be charged without arbitrary discrimination to all shippers alike under like conditions, the making of rates should, as far as possible, have all the elasticity necessary to permit the development of the traffic, and to produce the greatest results to the public, and to the railroads themselves."

Concerning automatic signaling devices, the Congress concluded, "That automatic signaling properly designed and installed, be recognized as a suitable means of protecting trains and switching movements. The Congress notes there has been much improvement and extension in automatic signaling since the last Congress, and that those who have used it have found it effective for their purposes. The Congress is not prepared to recommend automatic signaling for general installation to supersede existing systems, but it considers there are cases where this system may present general advantages."

Full of Instructive Matter.

Electricity Newspaper Company:

Gentlemen: Your sample copy of Electricity came to hand some time since. I have perused same very carefully and am sending you check for one year's subscription, as I do not know of any similar journal so full of instructive matter and splendid suggestions.

Your favor of April 29 in reference to Electricity has been preserved on my desk, and having again come to light this morning has served to remind me of my tardiness in sending in my subscription. I shall be glad to receive the next issue. I thank you for the sample copy and trust the coming numbers may afford as great interest.

With best wishes for your success, I am

Very respectfully,

O. H. Caldwell.

Ohio street and Capitol avenue, Indianapolis, Ind., May 8, 1905.

New York-Denver Special Train.

Arrangements have been completed for a special train of Pullman sleeping, dining, parlor, smoker and observation cars, via Pennsylvania and Burlington Railways, leaving New York at 10:25 A.M. Saturday, June 3, and running as the second section of the Limited, for the National Electric Light Association Convention. The train will arrive at Chicago at 8:25 A.M. June 4, leave at 11:15 the same morning, and arrive at Denver at 2:30 P.M. June 5.

Space has been engaged on this train for the following Eastern delegates: C. O. Baker, Jr., N. F. Brady, D. A. Bertolette, W. H. Blood and wife, J. F. Blauvelt, P. C. Brown, Charles B. Burleigh, H. J. Buddy, A. E. Carrier, C. H. Coit, H. F. Coggeshall and wife, J. S. Codman, W. P. Conover and wife, E. Corrigan, H. C. Cushing, Jr., H. P. Chandler, A. J. De Camp and wife, Miss De Camp, A. F. Dow and wife, W. C. L. Eglin, Miss Eglin, W. R. Eaton and wife, H. W. Fitz, D. Farrand and wife, S. S. Gleason, W. R. Gardner, W. P. Hancock, H. T. Hartman and wife, R. C. Hall, H. W. Hillman and wife, C. I. Hille, W.E. Holmes, C. H. Hodskinson and wife, Bert Houghton, Percy Ingalls and wife, E. H. Johnson, Harry Kirkland, C. A. Learned, C. E. Lucke, C. W. Lee, E. T. McCabe and wife, J. B. McCall and wife, N. C. McPherson, George Manson, T. C. Martin, K. G. Martin, Miss. Martin, W. E. Moore, H. P. Moore, Francis Murdock, I. E. Moultrop, A. H. Patterson, Warren Partridge, C. W. Price, George F. Porter, J. S. Pyle, H. E. Ryder, E. F. Rowell and wife, E. W. Rockafeller, Paul Spencer and wife, J. C. Spear and wife, H. L. Shippy, H. D. Simpson and wife, Orin Smith, George B. Stetson, George L. Smith and wife, C. E. Skinner and wife, Miss. Skinner, J. W. Wakeman and wife, Arthur Williams, J. S. Whitaker and P. S. Young.

A High Grade Bureau for Technical Employers and Employes.

In 1893, Frederick A. Peckham, at that time Western manager of the "Engineering News," in traveling over the country, had constant demands made upon him for competent help by technical companies, manufacturing interests and the like. In addition he was visited daily by men who wished him to help them to secure positions. Herein was the great need.

To meet this need, the Engineering Agency was started by Mr. Peckham, Monadnock Block, Chicago. During the 12 succeeding years, this Bureau has filled approximately 10,800 positions with competent technical men. This means that the wants of 21,600 employers and employes have been satisfied. One feature has been the supplying of instructors and professors for the principal colleges of engineering. It is significant that all these 10,800 men have been placed at maximum salaries. To-day, the agency has 500 open positions on its books. They must and will be filled. More men are coming. More vacancies are coming. The scope of the business is increasing magically. During the past two years, the registrations have exceeded 4,000. And still there is room. To reach the men needed, the Agency regularly uses the "want" columns of over 200 publications. It has spent thousands of dollars in advertising. And yet even this strenuous method has not coped adequately with the exigency. It has been necessary for the Agency to publish a new monthly journal, the "Engineering World." This publication has jumped into immediate popularity and surprised all connected with it. Inasmuch as it acts as an intermediary or agent between employer and employe, it stimulates hearty co-operation, in which neither forgets or neglects the other, and is unique in covering a broad and fertile field. It aims to be simple, interesting, of practical value. By such heroic measures as the foregoing, has the Engineering Agency met great needs.

Applicants for membership give complete records of past experience, and furnish references as will guard the Bureau in placing only skilled men. The experience of years, a reputation for unimpeachable reliability with the leading railroad, manufacturing and industrial companies, and up-to-date methods have made the Engineering Agency an influential corporation, whose assistance and counsel is sought by all classes from all parts of the civilized world.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED MAY 9, 1905.

Electric Railways and Appliances

789,171. Electric Signal System for Railways. Ara P. Rickmire, Rhinelander, Wis. Filed Aug. 11, 1904.

789,221. Electric Safety Appliance for Railway-Trains. John A. Larkin, Glen Ridge, N. J. Filed Nov. 12, 1903.

789,225. Underground Conduit for Electric Railways. John H. Munson, Chicago, Ill., assignor of one-half to Charles G. Hawley, same place. Filed July 10, 1896.

789,340. Contact Apparatus for Electric-Traction Systems. Ellsworth Sperry, South Windsor, and David F. Broderick, Hartford, Conn. Filed Nov. 4, 1904.

789,383. Electric Trolley. Charles L. Rogers, Uxbridge, Mass. Filed Nov 30, 1903.

789,613. Trolley-Wire Splicer. William L. Kerlin, Wyoming, O., assignor of one-half to Josiah Kirby, same place. Filed Jan. 4, 1905.

789,649. Electrofluid-Pressure Switching Mechanism. Walter J. Bell, Los Angeles, Cal., assignor of one-half to Leon F. Moss, same place. Filed Jan. 18, 1904.

789,666. Trolley. James W. Patterson, Cutler, O. Filed Jan. 5, 1905.

Electric Lights and Appliances

789,519. Electric-Drop-Light Bracket. Carl E. Zeisinger, Durand, Wis. Filed Aug. 13, 1904.

789,540. Globe-Holder. Charles E. Harthan, Lynn, Mass., assignor to the General Electric Company. Filed Feb. 9, 1903.

789,609. Arc-Electrode. Duncan A. Holmes, Samuel A. Tucker and Edward Van Wagenan, New York City. Filed Aug. 6, 1904.

789,618. Apparatus for Automatically Lighting Smudge-Pots. Henry H. Lyon, Riverside, Cal. Filed Nov. 21, 1903.

Electrical Machinery and Apparatus

789,365-366. Electric Snap-Switch and Electric Switch. Monroe Guett, Hartford, Conn., assignor to the Hart & Hegeman Manufacturing Company. Filed Nov. 16 and 18, 1903.

789,367. Electric Switch. Henry F. Keil, Bronxville, N. Y. Filed July 19, 1904.

789,377. Unsymmetrically-Wound Electric Motor. Frederick J. Newman, Chicago, Ill., assignor to the Woods Motor Vehicle Company, same place. Filed Jan. 9, 1905.

789,379. Static Electric Machine. Theodorus H. Patee, Greenfield, Ind. Filed June 14, 1901.

Telephones and Telephone Apparatus.

789,188. Combined Drop and Jack for Switchboards. Henry Tideman, Menominee, Mich. Filed Aug. 13, 1904.

789,208. Signal Instrument for Telephone-Substations. Henry M. Crane, New York City, assignor to the Western Electric Company, Chicago, Ill. Filed Jan. 2, 1904.

Miscellaneous.

789,161. Dental Electrode for Medicamental Diffusion. Samuel H. Linn, Rochester, N. Y. Filed Sept. 30, 1903. Renewed Sept. 19, 1904.

789,215. Apparatus for Galvanizing or Otherwise Plating Wire or Other Metallic Bodies. George A. Goodson, Providence, R. I., assignor to the Goodson Electric Galvanizing Company Minneapolis, Minn. Filed April 7, 1904.

789,239-240. Electric Signal System. Howell W. Souder, Tamaqua, Pa., assignor of one-half to W. D. Zehner, Lansford, Pa. Filed May 16 and 26, 1904.

789,256. Electrical Test Set. Alva J. Carter, Ida Grove, Iowa. Filed Dec. 23, 1902. Renewed April 4, 1905.

789,295. Electrical Cut-Out. William D. Packard, Warren, O. Filed May 8, 1903.

789,353. Plant for the Electrodeposition of Metals. Anson G. Betts, Troy, N. Y. Filed April 11, 1904.

789,378. Apparatus for Teaching Telegraphy. Howard G. Page, Fitchburg, Mass. Filed Sept. 26, 1904.

789,402. Electrical Collector. Peter Ackermann, Chicago, Ill. Filed Sept. 4, 1902.

789,411. Charging-Station for Electrically-Propelled Vehicles. Frank P. Cox and Charles E. Holmes, Lynn, Mass., assignors to the General Electric Company. Filed June 13, 1901.

789,419. Magnetic Controlling Device. Charles E. Eveleth and Oran O. Rider, Schenectady, N. Y., assignors to the General Electric Company. Filed June 3, 1903.

789,456. Automatic Rheostat. George H. Rupley, Schenectady, N. Y., assignor to the General Electric Company. Filed Sept. 20, 1901.

789,458. Lightning-Arrester. Howard R. Sargent, Schenectady, N. Y., assignor to the General Electric Company. Filed Aug. 28, 1902.

789,463. Reactive Coil. Elihu Thomson, Swampscott, Mass., assignor to the General Electric Company. Filed Oct. 1, 1904.

789,475. Circuit-Breaker. Jonathan E. Woodbridge, Schenectady, N. Y., assignor to the General Electric Company. Filed July 3, 1902.

789,488. Synchronism-Indicator. Paul L. Clark, Chicago, Ill., assignor to the General Electric Company. Filed Oct. 19, 1903.

789,508. Attaching-Plug. Howard R. Sargent, Schenectady, N. Y., assignor to the General Electric Company. Filed Oct. 9, 1902.

789,514. Storage-Battery Plate. Charles H. Whiting, New York City. Filed June 25, 1904.

789,515. Leading-in Conductor. Willis R. Whitney, Schenectady, N. Y., assignor to the General Electric Company. Filed Sept. 14, 1904.

789,523. Process of Electrolytically Refining Copper-Nickel Alloys. Anson G. Betts, Troy, N. Y. Filed April 11, 1904.

789,573. Insulator. Louis Steinberger, New York City. Filed July 17, 1903.

THE TELEPHONE WORLD.

California Independent Telepone Association Organized.

At a meeting held in Los Angeles May 5, in the office of the Home Telephone Company, an association of the Independent telephone companies was formed, to be known as the California Independent Telephone Association.

The aim of this organization is to bring about a closer relationship between the various Independent telephone companies operating in California. Meetings will be held the second Tuesday is each month, when matters pertaining to the betterment of service, the requirements of the various communities will be considered and acted upon. Constitution and bylaws were adopted and the following officers were elected:

President—John Van Liew, of Los Angeles.

First Vice-president—D. S. Parker, of Pomona.

Second Vice-president—Roscoe Howard, of San Diego.

Secretary—P. T. Spencer, of Whittier.

Treasurer—Will L. Frew, of Compton.

It is stated that few people realize the progress the Independent telephone movement has made in Southern California. The fact was brought out at the meeting that more than $10,000,000 is invested in telephone plants of the various Independent companies who are now operating 30 exchanges with over 30,000 telephones and toll line circuits reaching 110 towns in Southern California. All this being accomplished in less than two years.

A Clock to Regulate Telephone Talk.

A dispatch from Paris states that the Paris telephone administration has introduced into its public offices a register with a clock face —like the taximeter —the circumference whereof indicates 12 minutes, divided into units of conversation periods, namely, three, six and nine minutes When the machine is set going the person using the telephone can see precisely how long he has been speaking.

The Pennsylvania Telephone Company is about establishing an automatic exchange at Fleetwood, similar to those at Palmyra and Birdsboro. The necessary number of subscribers having been secured, the men are now engaged in arranging the details. The subscribers live in Fleetwood and surrounding districts.

The Valdez, Marshall Pass & Northern Railroad has been incorporated, to build and operate a railroad and telegraph and telephone lines from the eastern shore of Valdez Bay, 413 miles, to Eagle City, on the Yukon River, Alaska.

At a recent meeting of the selectmen of Newport, Me., it was voted to give the Plymouth Telephone Company the right to erect poles and to string wires on the streets of that village and it is understood that this will be done at some time in the near future.

In Robeline, La., a telephone system has been subscribed for, both long-distance and local, and its construction is in progress.

Annual Meeting Shows Rapid Extension.

The Nuckolls County Telephone Company held its annual meeting in Nelson, Neb., this month, and nearly all the shares that have been issued were represented. A statement of the company's condition shows total expenditures to date are $15,472.31; total indebtedness, $7,677.22; material on hand, $2,062.00; average investment for year, $4,360; rents and tolls to date, $1,609.56; operating expenses, $334.97. The capital stock was increased to $50,000, the time of the annual meeting was changed from May 1 to the first Tuesday in April, and the number of directors reduced from 17 to 7. After a lengthy and animated discussion it was agreed to issue bonds not to exceed $10,000.

The board of directors for the coming year was elected as follows: S. A. Lapp, J. C. Day, J. C. Chamberlain, B. F. Scroggin, J. A. Wehrman, W. A. Voigt and J. R. Parsons.

During its one year of operation the company has erected 127 miles of lines, installed 260 'phones and established exchanges at Ruskin, Nora, Cadams, Oak and Angus.

Telephone Bids Wanted.

The Interior Department has given notice that sealed proposals will be opened June 1 at the office of the U. S Reclamation Service Office, Glendive, Mont., for installing, in connection with the Fort Buford reclamation project, a telephone system having four telephone stations and about 70 miles of pole line, beginning opposite Glendive and ending at a point nearly opposite Fort Buford. Specifications, forms of proposal and particulars may be obtained by applying to the chief engineer of the Reclamation Service, Washington, D. C., or to F. C. Weymouth, engineer, Glendive, Mont.

Plans are being perfected by the Southern New England Telephone Company of Boston, Mass., for a rural service by which the farmers and others will have the use of telephones at a minimum cost of 75 cents per month. The farmers are to construct their own lines and furnish poles and labor, the company supplying wire and telephones. The farmers will own the lines and keep them in repair, the company keeping the telephones in order.

The Missouri, Kansas & Texas Telephone Company has filed a mortgage of $1,250,000 to the Old Colonial Trust Company of New York in the register of deeds' office Kansas City, Kan. The mortgage is to secure the 5 per cent. bonds issued in 1899, on wire and equipment.

The United States Government will establish in the fifth life-saving district a system of patrol telephones extending from Cape May to Sandy Hook. Work will begin soon that the system may be ready when the crews are put on, August 1.

The North Collins, N. Y., Telephone Company has increased its capital stock from $5,000 to $10,000.

The Goodhead Telephone Company, of Winchester, Ill, has changed its name to the Scott County Telephone Company.

Farmers Want Telephones.

At a recent meeting of the farmers of the southeast part of Oklahoma County, held in Oklahoma City, Okla., it was practically decided to put in a system of rural telephones, with city connections. The Pioneer Telephone Company of that city has made the farmers a proposition to furnish them with instruments and maintain the line at $1 per month after it is built. Some opposition was at first made to the city connection, but this was voted down almost unanimously after some discussion, as the convenience of the city connection was shown to be one of the most important features To start with there will be about 50 telephones, and these will have city connections so that the farmer may transact a considarable amount of business with his city brothers. This plan of communication is being established in many parts of the territory and is giving satisfaction.

Announcement was recently made that the Wayne-Monroe Telephone Company has secured possession of the Kelly exchange at Newark, N. Y. The Kelly system was established in the town of Arcadia several years ago and is now the largest system in any one town in Wayne County. It was recently overhauled and several thousand dollars spent in placing it in excellent condition. The deal is considered the most important one that has been made in several months in telephone matters. The toll business is large. It will be handled between the Wayne-Monroe and the Interocean into Rochester and Buffalo and Western New York. The board of directors has elected John A. Driscoll, general manager and president; Judson L. Transue, secretary and treasurer; Dr. J. S. Brandt, Albert Yeomans and Judson L. Transue, executive committee.

The recent annual meeting of the stockholders of the Albany, N. Y., Home Telephone Company was held at the Exchange Building. The following officers were elected: President, Howard Hendrickson; vice president, Irving H. Griswold; treasurer; George C. Lee, Jr.; secretary, Henry J. Prince, Jr. The annual report showed a gratifying increase in business and a large addition to the surplus and earnings of the company.

C. W. Scott, of the Deposit, N. Y., telephone exchange, is building a new line to Hambletville and China. He will also make connections with North Sanford as soon as possible.

The Northeastern Telephone Company is extending its lines at East Gorham, Me.

Telephone Incorporations.

The Albany Telephone & Telegraph Company, Albany, Me. Capital stock, $3,000. Officers: President, Amos G. Bean; treasurer, Lucius J. Andrews, both of Albany.

The Sherburne County Telephone Company, Elk River, Minn. Capital stock, $50,000; Incorporators: J. C. Jacobson, George Patterson, Charles F. Knapp and Jesse A. Gutzler.

The Coventry & Greene Telephone Company, Greene, N Y. Capital stock $1,000. Incorporators: Dr. George O. Williams, Dr. Frank Preston and Matthew F Smith, Coventry.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Auburn, N. Y.—The city council has let the contract for lighting the city with electricity to the Auburn Light, Heat & Power Company.

Glenwood, Ia.—The Glenwood electric light plant is to be enlarged and improved.

Guthrie, Okla.—The Guthrie Electric Light & Power Company, of which Thomas H. Smith is president, will enlarge its plant in the near future.

Harrington, Wash.—Mr. Brodie, of the firm of Shaw & Brodie, promoters of the Harrington electric light system, will soon complete the light plant here.

Haverhill, Mass.—E. P. Shaw has made a proposition to the Amesbury Electric Light, Heat & Power Company to supply electric light at Salisbury Beach.

Knoxville, Ill.—It is probable that the Electric Light Company of this city will extend its wires to Gilson and Maquon.

McComb, O.—The electric light plant has been purchased by this town for $5,000. Bonds will be issued to pay for the same.

Minneapolis, Minn.—A central lighting plant, supplying both gas and electricity, will be established in this city at a cost of about $50,000.

Monmouth, Ill.—This city has informally made an effort to purchase the electric light plant of the Monmouth Gas & Electric Company, and the matter is receiving the consideration of the officials of that company.

Paducah, Ky.—Work has been commenced on the construction of a new electric light plant here. David G. Wright, of St. Louis, Mo., representing St. Louis and New York capitalists, may be addressed.

Portland, Me.—The Centerville Light & Traction Company, of this city, capitalized with $500,000, has been incorporated by M. W. Baldwin, H. E. Mason and others, to operate an electric lighting plant.

Robeline, La.—This town is to be supplied with electric lights.

Rose City, Mich.—The Rose City Manufacturing Company is figuring on putting in a city electric lighting plant. Andrew King, an electrician of Bay City, has been figuring out the cost. Superintendent W. A. Humphrey will confer with Greif Brothers, of Cleveland, who own the plant of the company and thinks it probable that the city will soon be lighted by electricity.

Sandy Hill, N. Y.—The Glens Falls Electric Light Company has been given a 50-year franchise to operate in this village. Under the terms of this franchise the company must furnish incandescent lights for 10 cents per kilowatt hour, and supply current for manufacturing purposes at 5 cents per kilowatt hour.

Tower City, Pa.—H. T. Bressler has completed arrangements for the erection of a new electric plant to provide lights for this city, Williamstown, Lykens, Wiconisco, Reinerton and Johnstown. The plant will be located here.

Waterford, N. Y.—The Waterford Electric Light, Heat & Power Company has filed a certificate of increase of capital from $50,000 to $500,000.

Wynnewood, I. T.—This city will soon have electric lights.

STREET RAILWAYS.

Adrian, Mich.—The Toledo & Michigan Electric Railway Company, which plans to build an electric line between this city, Clayton, Janesville and other places, is offering for sale several blocks of its bonds. P. P. Duket is president of the company.

Amboy, Ill.—It is learned from a reliable source that the Illinois Central Railway Company plans to operate suburban service between here and Freeport by electric power instead of steam.

Atlanta, Ga.—Active steps have been taken looking to the immediate construction of the Atlanta-Macon Interurban Railway, a proposed new trolley line between this city and Macon.

Boyertown, Pa.—The city council has granted a franchise to the Boyertown-Palm Electric Railway Company to lay tracks on Reading and Philadelphia avenue, conditioned on the payment of $1,000 if the road is not built within one year, but with the clause "unless hindered by legal obstructions" not included. This proposed line will connect this city with the Oley Valley line, and passing through Gilbertsville, will form a connection at Limerick with the Schuykill Valley line.

Brookings, S. D.—Madison business men are considering the proposition of putting in an electric railway line from this city to Salem.

Catskill, N. Y.—The Catskill Electric Railway Company has filed with the Secretary of State a certificate of an extension of its lines in this town.

Clinton, Ill.—J. G. Eversham, private secretary of William B. McKinley, the electric railway magnate, was lately present at the meeting of the city council and was granted a franchise for the establishment of an electric line.

Elgin, Ill.—It is reported that an electric road will be built on the north route through Garden Prairie, Marengo and other cities.

Findlay, O.—An increase in the capital of the Lima, Findlay & Toledo Electric Railway has been made from $700,000 to $900,000.

Ft. Wayne, Ind.—J. Levering Jones, of Philadelphia, will erect an electric line between this city and Marion.

Hamilton, Tex.—S. S. Wright, one of the directors of the Municipal Bond & Trust Company, has closed a contract to build a trolley line from Dublin to this city.

Kansas City, Mo.—An electric line will be erected to connect this city with Excelsior Springs.

Lansing, Mich.—Jacob Stalb and Fred Thomas, the original stockholders of the company organized to construct the Lansing & St. John Electric Railway, will soon begin work.

Mexico, Mo.—It is announced that an electric line will be built from Jefferson City through here and north of Eldon, Ia. J. E. Houghan is interested in the enterprise.

Philadelphia, Pa.—The Philadelphia Rapid Transit Company will shortly award a contract for an addition to its power house in Wyoming avenue east of Third street. W. S. Twining, chief engineer, has the plans in his possession.

Red Bluff, Cal.—The California Promotion Committee is advised that a franchise has been granted and rights of way obtained for an electric railroad from here to Tuscan Springs, a distance of nine miles. Surveys have already been made, and it is said development work will start in 90 days.

San Francisco, Cal.—W. M. Gibson, of this city, has asked for a franchise in Santa Cruz, for an electric railroad from Chittenden to Watsonville.

Santa Ana, Cal.—The Pacific Electric Company will push construction on a line to this city and hopes to have it completed by October 1. The route is straightaway from Watts station to Santa Ana, a distance of 27 miles. The line from Huntington Park to Newport Beach also will be built at once.

Shawnee, O. T.—A franchise has been granted by the council of Tecumseh for an electric railway in that city, with the proviso that the promoter, Alfred Hart, president, of the Exchange Bank there, shall commence construction of a line to this city within 90 days. Mr. Hart put up a $5,000 bond to do the work. The two cities are only a short distance apart, and the new line will be connected here with Shawnee's electric line.

Terre Haute, Ind.—Tucker, Anthony & Co., have financed and will shortly build a high speed electric interurban road between Indianapolis and this city.

Waterloo, Ia.—The Mason City and Clear Lake Railway and the Waterloo, Cedar Falls & Northern Railway will consolidate the two systems, and contemplate constructing electric lines from Mason City to Waverly and from Sumner to West Union.

POWER PLANTS.

Albany, N. Y.—The Electric Power & Transmission Company of Niagara County has filed articles of incorporation with the Secretary of State. It has $5,000,000 capital, and may operate anywhere between Albany and Buffalo. Its directors are Edward B. Bruce, Allan C. Rearick, Edward E. Stowell, Frank H. Cole, New York, and John J. Daly, Brooklyn.

Riverside, Ill.—The Chicago & Southern Traction Company has purchased a site here and will erect a large power plant to cost about $100,000.

BIDS WANTED.

Washington, D. C.—Sealed bids will be received until May 31 at the office of Commissioners Henry B. F. McFarland, Henry L. West and John Biddle, for the construction and installation of a heating, lighting and power plant at the Industrial Home School at Blue Plains. A certified check for $1,000 is required.—The Navy Department, through the Bureau of Supplies and Accounts, is inviting sealed proposals until May 31, for furnishing various Eastern navy yards with the following supplies: Schedule 251, electrical wire; Schedule 253, battery cells; schedule 254, motors; schedule 256, insulating tape, etc. Blank proposals and detailed information can be obtained at the Navy Pay Office in New York, or upon application to the Bureau in this city. The Bureau will open bids on June 6, for furnishing an electric traveling crane. Intending bidders should call for schedule 245, which can be obtained at the Navy Pay Office in New York, or upon application to the Bureau.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 14⅞@15c.; Lake 14⅞@15c.; casting, 14⅝@14¾c.

The annual meeting of the Kansas City Railway & Light Company will be held in Jersey City on June 26.

The recent decline in the shares of the American Telephone Company (Bell) from 144 to 137½ has excited considerable interest.

The city of Chicago will appeal from Judge Grosscup's decision in the 99-year case whether the Union Traction Company does or not.

The American Graphophone Company has declared a dividend of 1 per cent. on its common stock, payable June 15, to holders of record June 1.

The annual report of the Chicago Edison Company recently made public shows an increase in net earnings of $100,995. Dividend payments increased about $70,000.

The American Railways Company (Philadelphia) has declared the regular quarterly dividend of 1½ per cent., payable June 15 to stock of record May 31.

The annual report of the Commonwealth Electric Company of Chicago shows an increase in net earnings of about $72,000 and an increase in gross earnings of about $450,000.

President John I. Beggs of the National Electric Company, Milwaukee, Wis., who was recently elected to succeed S. W. Watkins, announces that the company would either be reorganized or sold to outside persons.

E. W. Moore of the Everett-Moore Syndicate says that the Toledo (O) Railways & Light dividend will probably be increased to 3 per cent. and finally to 4 per cent. He says the present dividend rate will surely be maintained.

The Montreal Street Railway Company announces that the issue of $1,000,000 bonds for extensions has been indefinitely postponed. Legal formalities must be arranged before the shareholders can be asked to ratify the issue.
